NOTE.—There is a model of St. Helena in the Rotunda, at the Royal Academy, Woolwich; also a collection of its rocks, minerals, and soils in the Sedgwick Museum, Cambridge. A collection of dried indigenous plants exists in The Herbarium, Royal Botanic Gardens, Kew. A collection of marine fishes, birds, and insects is at The Natural History Museum, South Kensington, W.; and much valuable literature, relating to the island, is to be found in the Library of the Royal Colonial Institute, Northumberland-avenue, W.C.

DISCUSSION.

The CHAIRMAN (Sir William Hood Treacher), in opening the discussion, said that the little island of St. Helena was of peculiar interest so far as its fauna and flora were concerned, because it produced 50 different kinds of plants, 20 varieties of marine fish, 20 species of land shells, and 120 sorts of beetles which were found nowhere else on the globe. The problems there presented to naturalists, zoologists, and geologists had not yet been solved, but a not altogether improbable hypothesis which might solve the conundrum was, he believed, that the island was a relic of a vast submerged continent. The author had stated that nearly all the flowering shrubs produced pure white flowers; that the island was free from earthquakes and other atmospheric disturbances, and also from malarial fever and lawyers, so that it would seem to be a little earthly paradise; a statement tempered somewhat by the fact that occasionally, even in dead calms, rollers lifted big vessels out of their anchorage and laid them broadside on the shore. It had been described by a Russian traveller as an emerald set in granite. The island was called after St. Helĕna, and, that being so, he wished to ask the author why it was always called St. Helēna? St. Helena was the mother of Constantine the Great, one of the first of the noble Roman ladies baptised into Christianity, and it was stated in one account of her life she was a native of Britain. It, therefore, seemed fitting that the little emerald set in granite should be one of the natural jewels of the British Crown, and it seemed a pity that this great nation could not afford a little financial assistance to the island, which had fallen on bad times, not through its own fault in any way, but simply because a Frenchman cut the Suez Canal, and because the British nation had no more prisoners of war who required board and lodging. The author had stated that the island was still of great imperial importance, and he was sure all present would wish good luck to the efforts of the St. Helena Committee, which was trying to soften the hard hearts of the Colonial Office, although he believed no Government office had any hearts to soften. At any rate the real invincible person whom they could not get over was the Chancellor of the Exchequer. Having regard to the present state of public opinion he was afraid there was very little chance of St. Helena being re-garrisoned, so that the fortifications which were re-constructed not many years ago would moulder into decay. He had read that whale fishing used to be a great industry with the islanders, from £13,000 to £30,000 a year being obtained from it. The author had not referred to that subject, and it would be interesting to know whether the whale fishing still existed, or whether the statement was a myth.

MR. A. G. WISE (Secretary of the St. Helena Committee) desired to remove a misconception that

had arisen with regard to the purpose of the St. Helena Committee. It had aimed at relieving the distress on the island, and it had endeavoured, not altogether without success, to soften the hearts of the Colonial Office and the Chancellor of the Exchequer; but it had not appealed to the public, nor was it the intention to do so, for funds to distribute as charity among the islanders. Lord Elgin, when he was Secretary of State for the Colonies, thought that would be a proper course for the Committee to pursue, but after carefully considering the matter, the Committee decided that it was not their place to be a kind of Charity Organisation Society, but that it was an Imperial duty to get the island out of the mess into which the Government had put it. Mr. Haldane pointed out with triumph that by withdrawing the troops from St. Helena a saving of £35,000 per annum had been effected, but it it did not seem a large order to suggest that some of that money should be spent in starting reproductive industries for the benefit of the island. That view had been adopted to a certain extent, £5,000 being voted for starting of a flax industry and £500 for the commencement of a lace industry for the women and children. While the flax industry had been fairly successful, he had just heard from the island that in all probability it would be necesssary to close down the factory for three months, because there was not a sufficiency of the flax to enable it to go on working. That was due to the fact that there were 2,000 head of cattle on the island, which, so long as they were allowed to remain, made it impossible for the flax industry to be a success. The Admiralty had made an offer to purchase 200 head of cattle, but the amount offered was not such as the farmers could accept, and the committee were now urging upon the Colonial Office to make a grant of about £1,000 to supplement the offer made. The Admiralty pointed out that they were not a philanthropic body, and could not offer more than the definite market value of the cattle, which were wanted for naval requirements on the Cape station. He maintained there was some kind of Imperial obligation in regard to the question of cattle, because, at the request of former Governors, and for the benefit of the military, the farmers were continually asked to improve the breed of their live stock, being assured that they would always be taken for military purposes. Those promises had not been fulfilled, with the result that the farmers had been left with 2,000 cattle on their hands which were practically useless, as the people on the island were unable, owing to their poverty, to purchase meat. The cattle were a great impediment to the growing of the flax because if they were not there the pasture lands they now occupied would be used for the cultivation of that plant. The Committee had learned with great interest that the Salvation Army had formulated a scheme in connection with the island. It was necessary to avoid any tendency to exaggerate the state of affairs in the island. The latest official report which was, unfortunately, two years old, stated that two children had died of starvation, the Governor reporting that it was due to the apathy of the parents. Personally he could not conceive any parent being so inhuman, and although the Governor of St. Helena had done his work admirably, he thought there must be some kind of official negligence if such a condition of affairs existed. His latest information was to the effect that there was a very slight tendency towards improvement, but the present state of things could not go on for long. The labouring classes could only get occasional employment at very low wages; this re-acted on the merchants and farmers, and consequently things were at a very low ebb all round. He, therefore, contended it was the bounden duty of the Government to come to the rescue of the island.

Mr. B. R. BALFOUR stated that some years ago he spent a few months on the island in the capacity of a lay reader, the clergy being very short of help. Between 4,000 and 5,000 Boer prisoners of war were then resident there. He noticed that the roads on the island were in a very bad state, and thought it was a pity some attempt was not made to utilise the services of the prisoners in repairing them, as they were very glad to do any kind of work, particularly gardening. While there were some depressing items in the Governor's Report, there were also some encouraging features, among them being the statements that the jail was empty for 116 days of the year, and that on some occasions, when acting as Judge, he had been presented with a pair of white gloves on account of the absence of crime. The Governor further stated that he believed the new industry of flax growing was likely to be prosperous; and that if the owners of property would all pull together and work for the benefit of the island progress would be made. The climate in the higher part of the island was exceedingly good, but he would not recommend anyone to settle in Jamestown, the town being hemmed in between huge masses of rock which had the effect of making the place very hot. The St. Helena Committee had suggested that the island might be made a tourist resort, and he thought it would be an exceedingly good thing for the island if somebody with capital converted one of the many available houses into a first-rate hotel, which would induce people to go there. There was only one doctor on the island, who received a very small salary, and he suggested the Government should make a larger grant in this direction. Much benefit to St. Helena might also result if trees were planted there. He hoped the paper would have the result of interesting the people of this country in an out-of-the-way island which was in need of help.

On the motion of the CHAIRMAN, a hearty vote of

thanks was accorded to Mr. Melliss for his interesting paper.

Mr. MELLISS, in reply, said a good deal of difference of opinion existed with regard to the question of the pronunciation of the name of the island, but it had never been satisfactorily proved why it should be called St. Helēna. He believed the whale fishing was still carried on, but entirely by a large American fleet, so that it was not of much benefit to the island, the ships only obtaining a certain amount of fresh water and provisions from it.

JAPANESE EXHIBITION IN LONDON.

The Times announces that it is officially informed that an exhibition of the arts, sciences, manufactures, industries, and products of Great Britain and Japan, on an extensive scale, will be held at Shepherd's-bush next year.

The Imperial Japanese Government are supporting the scheme with keen interest, and financial aid will also be forthcoming. A Bill relating to the exhibition has just received the approbation of the Imperial Diet, and in the case of the House of Representatives the sanction was given unanimously.

There is reason to believe that the British Government are also in sympathy with the project.

Some officials of the Japanese Department of Agriculture and Commerce sent by the Government have lately been in London, and they have returned to Japan, after having concluded satisfactory arrangements with the British organisers.

Distinguished personages in this country have already identified themselves with the proposed exhibition, and signs are not lacking that it will prove to be a very important and successful event in the coming year.

DRYING PLANT FOR INDIA.

The Director-General for Commercial Intelligence, India (Mr. F. Noel-Paton), draws attention to the need in India for special drying plants capable of dealing with the conditions as regards atmospheric humidity existent in that country. In the rainy season certain industries in India suffer from the difficulty of drying their products or materials.

An example of this is furnished by the flour-milling industry in India. The ordinary wheat of Indian commerce contains a relatively large percentage of dirt, although the penalties imposed under the export contract now in force has tended to abate this defect so far as grain for shipment is concerned. Before wheat in a dirty state can be milled, it must be not only screened and scrubbed but washed, and the process of subsequent drying is troublesome, costly, and at times injurious. The usual method is that the wet wheat after passing through a centrifuge is discharged into the head of a vertical shaft containing baffles, and as it descends it meets an ascending current of increasingly hot air from gills that are heated by steam. This method is successful except in the rains; but during the rains the miller must let his wheat go to the silo and ultimately to the rolls with an excessive percentage of moisture, seeing that an indefinite intensification of the heat results in destruction of the starch globules, and consequent injury to the flour. The excessive moisture is apt to entail inefficient milling and a decline in the percentage of fine flour in relation to offals. This is to some extent made good by the larger percentage of water sold as flour, but to an equal extent the flour loses value in the eyes of the baker. The baker founds his estimation of a flour largely on the weight of bread he can produce from a given measure of it, and this depends mainly on the quantity of water that may safely be added to it; and, in fact, the effort to reduce moisture in flour during the rains to such proportions as will insure the keeping qualities of the product is often attended by injury resulting from the employment of an injuriously high temperature. Indian bakers know that the processes of their calling are fraught with peculiar difficulties in the rains, not only because of accidents to the yeast, but because of the comparative weakness of the flour and its liability to decomposition of various kinds.

The tanning industry would also gain greatly by an appliance that would dry the air in the monsoon without reliance on condensation processes. In one large tannery in India no attempt to dry hides is made during two months of the year. This, of course, involves serious interference with the ordinary course of manufacture and an incomplete employment of capital. In some parts of the country the most serious difficulty is that of retarding the drying of the hides during the hot weather. At other seasons drying is artificially and very slowly effected by the use of steam pipes. The hides are suspended over and above these pipes; but the saturation of the atmosphere is such that the drying process occupies a number of days. During that time the hides have to be frequently wiped to free them from the moulds that grow profusely under such conditions; but it need scarcely be said that those moulds work considerable mischief in the course of a week or so, and even if they are superficially removed they may leave their spores in the leather to germinate so soon as favourable conditions recur, as they frequently do in India.

In the manufacture of sugar, deterioration in colour results from the creation of invert sugar during drying. At present a relatively low colour as distinguishing the indigenous article is considered a recommendation in some Indian markets, but in India as a whole the consumption of true refined sugar is increasing steadily and the prejudice referred to cannot be expected to persist. The drying of sugar after it leaves

the centrifuge is commonly effected by means of a cylinder that is heated by steam and rotates upon an inclined axis. But when the air is virtually saturated, a disproportionate expenditure of heat is necessary to impart to it any drying power.

So also in the drying of copra and in the desiccation of plantains for plantain meal and of various substances for the production of starch, it is the custom in other countries to rely upon a simple heating of the atmospheric air with such measure of humidity as may be present. But several of these substances are not only peculiarly liable to decomposition and discolouration through prolongation of the process of drying, but are also sensitive as regards excessive heat. There is reason to believe that if a suitable drying plant were devised a very great stimulus might be given to these industries, which are already attracting considerable interest.

In all these cases the drying is conducted or attempted by raising the temperature of a damp air to such a point that it may be enabled to assimilate more moisture. But in proportion as the humidity of the air increases any increment in temperature becomes more injurious. It would, therefore, be preferable to desiccate the air and pass it over the goods to be dried.

There are also other processes, such as wool-washing and the scrubbing of seed lac, to which an apparatus of the kind in question might not improbably be applied with advantage.

COMMERCIAL USES OF THE DOGFISH.

Fishermen on the Nova Scotia coast have been complaining for some time past about the prevalence of the dogfish, which is proving very destructive, as the pests not only take the bait, but often destroy the trawls and scare the fish from the fishing grounds, besides destroying large quantities of them. Very recently the dogfish has been on the increase, and, naturally, more hurtful to the fishing industry; but action has now been taken to make the pest financially valuable. According to the American Consul at Yarmouth, Nova Scotia, a dogfish reduction factory was established, about a year ago, at Canso, on the north-eastern coast of Nova Scotia, and large quantities of these fish have been treated there. In fact the works became so beneficial that the plant has been largely increased, and has become very remunerative to the proprietors as well as to the fishermen. Another plant has recently been established at Clark's Harbour, about thirty-five miles from Yarmouth. There is also a third at Shipegan, in New Brunswick. The Clark's Harbour plant is larger, and is said to be better and more modern than either of the others. The building is 138 by 40 feet. and has a very perfect machinery equipment. A splendid wharf has been built, leading out to the deep water, to facilitate loading. The fish are taken from the vessels and piled into wagons and carried to the "cooker," which is a long iron cylinder boiler-like affair. Steam is forced into this cylinder from both ends, and the fish thoroughly cooked, when they are transported to the press, where the oil is extracted. From the press the oil flows into tanks arranged with steam-pipes at the bottom, and supplied with water. The oil floating in the first tank is drained off through a conduit to the next tank, and so on to the fifth and last, when it is perfectly clear, drawn off into casks, and is ready for the market. Up to the present time New York has taken all the output of the factory, and also all that from the Canso works, the average price being 1s. 4d. per gallon. After the oil is drained off, the remains of the fish fall into a screw conveyer and are taken to the dryer, to which dry heat is supplied from a large brick furnace, a steam driver forcing the air into the dryer, after which the fertiliser is conveyed by a screw conveyer to the packing-room, where it is put into bags, for sale to the farmers of the country. With the exception of the 40 horse-power engine, which was built in Nova Scotia, all the machinery comes from New York. The Canso works are planned for day and night work, and reduce about twenty-five tons of fish in twenty-four hours. The Clark's Harbour plant will, it is said, reduce thirty tons of fish in ten hours, employing from ten to twelve men. These are Dominion Government plants. Not only will dogfish be utilised and reduced to useful fish oil and fertiliser, but all kinds of fish offal will be made use of and reduced to a commercial value. Much that is now useless to the fishermen and thrown away, will find a ready sale, and will add very considerably to the fishermen's profits. It is not expected that the local fishermen can supply material enough to keep the factories fully working, but small vessels will be employed, and collecting stations established along the coast, for the purpose of obtaining the dogfish and other non-eatable fish, and fish remains. Fishermen are greatly pleased with this new industry, as it will make a market for thousands of pounds of fish otherwise useless. These dogfish have been caught in the past in large quantities, and, after being killed, thrown overboard, but now they may become valuable, and, in a way, will prove of commercial importance.

TURKISH MEERSCHAUM DEPOSITS.

Meerschaum is mined at Kahe, in the vilayet of Angora, but principally in the Eski-Shehr. It is found in nodular form. At one time the fuller's earth, found about three feet thick overlying the meerschaum deposits, was collected and shipped to the coast, but this industry has died out, and the mining of the meerschaum alone is of commercial interest. Any person wishing to mine this substance can obtain a permit to do so from the Turkish Administration of Mines. It is said that the pits at Nemlau have been worked for two thousand years.

The meerschaum mined here is, according to the American Consul-General at Constantinople, in small yellowish nuggets, very resistant and compact. The meerschaum mines, which at one time reached from Kahe to Mihalitch, on the Sea of Marmora, are to-day reduced to some twelve hundred and seventy pits, concentrated round the city of Eski-Shehr, and giving employment to some five thousand miners. These mines are worked in the most primitive manner by a foreman and two to five workmen, with picks. The depths of the pits vary greatly, and depend upon the depth at which a reddish-brown earth is met, which is the first indication of the existence of magnesite. Sometimes this red earth is found only a few yards beneath the surface, but ordinarily at a depth of twenty yards, often forty, and even sixty. In this layer of red earth meerschaum is fonnd, disseminated in nuggets of irregular shape. The size of these rarely exceeds twelve to sixteen cubic inches; the greater part are of the size of a walnut. When the diggers reach this stratum they continue their working in one or two horizontal galleries, leaving natural columns. No explosives are necessary as there are no rocks. Some of these galleries have a length of over four hundred yards, and, as they are dug without any plan, it is not uncommon for two properties to meet. The first treatment received by the meerschaum after being brought to the surface is to clear it from the adhering earthy matter by scraping with a special knife. In this state it is sold to the local merchants, who dry and clean it, polish it with wax, and then sort it into qualities and sizes. There are thirteen recognised qualities, and these are again assorted into four principal sizes, the names of which and the number of pieces to the case are as follows:—Lager (*sira-mali*), 30 to 40; gross baumvolle (*biri-binlik*), 70 to 90; klein baumvolle (*pamoukli*), 140 to 170; soliste kaeten (*taneli*), 300 to 350. These are the principal sizes, but there are four smaller sizes, of which each case contains the following number of pieces: 500, 800, 1,200, and 1,500. These smaller cases are classed in only two qualities. There are two standard sizes of cases. For the first three sizes of nuggets, the case is 6¾ by 13½ by 28 inches, and for the five other sizes, 7½ by 14¾ by 32 inches. These are the sizes recognised by the Government, no other sizes being permitted. The prices of these cases are as follows, according to the size and quality of the nodules:—Sira-mali, from £18 10s. to £45 17s.; biri-binlik, from £11 to £18 19s.; pamoulki, from £4 12s. to £9 4s.; taneli, from £1 17s. to £3 14s. There is much waste in preparing the product for the market, the adherence of earthy matter thereto rendering it useless. Almost the entire output of the article is sent to Vienna, and thence distributed to the various European countries and to the United States, the latter country taking only the first four sizes, and that only in the first seven qualities. The United States is considered to be the best customer, and it therefore seems surprising that American purchases should not be made on the spot, or through Constantinople instead of through Vienna. If the Turkish meerschaum mines were developed they would be an important source of income to the Empire. Derindge, in the Gulf of Ismidt, which is connected by the Anatolian railway with Eski-Shehr, is the port of shipment for meerschaum. Shipments for Austria are sent *viâ* Trieste, and those for France *viâ* Marseilles.

HOME INDUSTRIES.

The Port of London.—Yesterday, the Port of London Act came into operation, and brings with it the new Port Authority, whose duty it will be to deal with the whole business of the Thames, from its mouth to Teddington. The Port of London Authority will be responsible for the administration of what has long been, and under sagacious control may long continue to be, the greatest port in the world. Into it pass every year some 5,000 vessels, of a total tonnage of, in round figures, 34,000,000, the value of their cargoes, outward and inward, being estimated at not less than £400,000,000. The docks cover a superficies of 640 acres of water and 1,800 acres of land, and have a capital value of £25,000,000. As Sir Hudson Kearley pointed out at the first meeting of the Port of London Authority, held a few days ago, rival ports, not only on the Continent, but in this country also, by the wise expenditure of capital have been enabled to keep abreast of the requirements of the day. Circumstances, unfortunately, have prevented London from doing all that is necessary in this respect, and the reason is not far to seek. There has been paralysing division of authority. Interests have worked in different ways, and without larger authority and revenue powers than Parliament has been willing to entrust to them, those responsible for making provision for the trade of the Port have done much less than was necessary. The new Authority comes into existence with adequate administrative and financial powers, it is admirably constituted, and there is confident expectation that it will be equal to its opportunities. German and Belgian ports are serious competitors now-a-days, but the splendid natural advantages of the Port of London; its geographical position; the magnitude, wealth, and energy of the population behind it; the fine approach from the sea; the river tides, strong enough to transport traffic easily to all parts yet not so violent as to make navigation difficult; these and other advantages insure the continued pre-eminence of the Port of London if only there is systematic execution of adequate improvements.

The Trade Boards' Bill.—The President of the Board of Trade has introduced his Bill to abolish sweating and establish a minimum wage. It is proposed to schedule certain trades in which "by

reason of the prevalence of evil conditions no organisation has yet taken root, and, in consequence, no parity of bargaining power can be said to exist." Certain trades are scheduled; others may be added by and bye. The scheduled trades are four—ready-made and wholesale bespoke tailoring; card-board box making; machine-made lace and net finishing; and ready-made blouse making. The want of natural organisation is to be met by setting up an artificial organisation for these sweated industries. The Trade Boards are to consist of representatives of masters and workpeople in equal numbers, together with official members nominated by the Board of Trade. One of them is always to be chairman, while there can be no quorum unless one of them is present. The primary duty of these Trade Boards is to regulate the rates of wages by establishing a *minimum* wage for the trade or branch of a trade with which they are concerned. When their decisions have been confirmed by the Board of Trade they are to be binding upon all employers, who may not pay anything less than the *minimum* under penalties enforceable in any court of summary jurisdiction. Officers appointed by the Trade Boards or the Board of Trade will have full power to inspect books, documents, or premises, and to prosecute in person without recourse to a lawyer. Everyone will sympathise with the object of the Bill. It remains to be seen whether, assuming it becomes law, it will effect the object aimed at, or materially improve the condition of the class it is intended to assist. It has to be remembered that these sweated trades are poor trades from every point of view, and there are those who think that if the Act succeeds in killing the sweating it will kill the trade altogether.

The Victoria Experiment.—The Bill is frankly experimental, and the proposed limitation of its operations, to begin with, seems wise. Of course, the principle of the *minimum* rate is no new principle in this country. In all Government works fixed minimum rates exist for the different classes of labour employed. Collective bargaining has given the great organised trades such rates for themselves. The mining, the engineering, and the cotton industries have them. Others have succeeded in setting up similar standards by means ot arbitration under the Board of Trade, when the arbitrator, sitting as chairman of a joint committee of employers and employed, has fixed piece-work rates for industries like the boot and shoe trade, and even for so complicated an industry as the Nottingham lace trade with success. In Australia the Special Boards Legislation of Victoria furnishes something more than a working model of Wages Boards. Victoria started her system of Wages Boards in 1896 with five special Boards, which in 1907 had multiplied to forty-nine. The trades chosen for the first experiments were the most heavily sweated in Melbourne—clothing, boot and shoe making, shirt making, furniture, and bread making. The first Wages Boards Act was passed for four years only, in the teeth of considerable opposition from the representatives of employers in the Legislature. But when the time came for renewing the Act some of its leading opponents supported its re-enactment, not only as an engine for putting down sweating, but as a useful instrument for the suppression of the dishonest employer, and the Act has now been made permanent. In his report on "the Wages Boards and Industrial Conciliation and Arbitration Acts of Australia and New Zealand," Mr. Aves says that as regards sweating "there is abundant testimony to the fact of improvement, under Wages Boards." He states that in the matter of "levelling up," the Boards "may almost be regarded as having won general approval," and he alludes to the "widely-spread belief that the Boards have been instrumental in diminishing, some say in abolishing, sweating." The Bill now before Parliament is not identical with the Victorian Act, but it proceeds on the same lines, and its operation will be watched with keen interest and even anxiety.

Short Time in the Spinning Industry. — The replies to the circular sent out by the Federation to spinners of American cotton does not justify any recommendation to a general decrease in production. As anticipated in these Notes, the necessary four-fifths majority was not obtained. It is the new mills that have been the determining factor in the rejection of the short time policy, and individual spinners must now consider what is best in the individual case. Many spinners are already running short time. The cotton trade could hardly be worse than it is just now. Short time would seem to be particularly suited to those definite and general contractions in the demand for labour due to what may be called cyclical fluctuations. The method was applied with great success in the severe depression of 1903-4. In the previous year the Federation of Master Cotton Spinners passed a resolution to close their mills during the whole of Whit week, and on every Saturday and Monday, from the 27th June onward. The effect was to reduce the normal week from 55 to 40 hours. This first period of short time ended in the autumn of 1903, but after a short interval of slightly improved activity short time was reimposed in the spring of 1904, and lasted till September or October, when the depression gave way to extreme prosperity.

Traders and the Railway Amalgamation.—There has been considerable anxiety among traders and others using the lines affected at the possible results of the working union proposed by the Great Northern, Great Central, and Great Eastern Railway Companies, but the new clauses which these companies have agreed with the Board of Trade to insert into their Bill for amalgamation should go far to allay this anxiety. As is generally known, the conveyance rate per mile for merchandise falls as the distance increases, the highest scale of charges operating for

the first twenty miles, or any part of such distance. The charges are lower for the next thirty miles, lower again for the next fifty miles, and still lower for the remainder of the distance. It was reasonable to stipulate that in the calculation of minimum rates for merchandise conveyed over the railways of the three companies, or any two of them, the distance should be reckoned continuously as one railway, and thus avoid more than one application of the higher rates. This has been secured by the first of the clauses referred to above. The second provides that the ordinary passenger fares in force on the railways of the three companies on the date of the passing of the Act (including the charges for season tickets, market tickets, and week-end tickets), shall not be increased by reason of the passing of the Act, or at all unless the Joint Committee can prove on complaint that such increase is not due directly or indirectly to the passing of the Act. And much the same stipulation is to be enforced in respect of the rates and charges of merchandise and minerals, whilst Clause IV. provides that the facilities as a whole afforded by the Joint Committee for either passengers, goods, or mineral traffic shall not be unreasonably diminished as compared with the facilities afforded by the companies during the year 1908. And compensation is to be provided for servants of the companies in their permanent employment prior to the 1st of January, 1908, who shall be discharged by reason of the passing of the Act.

CORRESPONDENCE.

THE WOOLLEN AND WORSTED INDUSTRIES.

Your paragraph on this subject in last week's *Journal* is certainly misleading not to say inaccurate. The term "woollen industry" is by no means confined to the shoddy manufacturers in the heavy woollen district, nor is the term "worsted industry" confined to those who use raw wools. Dewsbury, Batley and the Calder Valley are known as the "heavy woollen district." but outside those districts there are large centres manufacturing woollen goods and using large quantities of raw wool, such as Huddersfield, the Spen Valley, Leeds, Hawick, &c. With regard to raw wools the long wools are combed for the "worsted" industry, whilst short wools are carded and used for the "woollen" trade. Now with regard to London giving up its place to Bradford for the sale of Colonial wools at auction, there is another side of the question which has to be carefully considered, viz., the effect it would have on the foreign trade for colonial wools.

London is a port and all the wools are stored and inspected by buyers at the docks or in the neighbourhood, and consequently can be re-exported at a minimum of expense.

Bradford, on the other hand, is far inland and if the auctions were held there a large expense would be entailed on wools for re-export viz., carriage by rail from the port to Bradford and back again to the port.

At the sales just closed in London 187,252 bales were catalogued and 182,000 sold as follows:—To the home trade, 95,000 bales; to the Continent, 69,000 bales: to America, 18,000 bales. It will thus be seen that nearly half went abroad and if these had been sold in Bradford an additional expense of about 3-16ths per lb. for inland carriage would have been entailed to foreign buyers, or a total sum of nearly £20,000.

The question is, would this not have the effect of driving these foreign buyers away, direct to the sources of supply, and thus losing a large commission to those engaged in the trade in this country. Bradford is undoubtedly a very large user of Colonial wools and is entitled to every consideration, but before making such a stupendous change the question would require careful consideration from every standpoint.

QUESTIONS AND ANSWERS.

ANSWERS TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

What is the relation of the two practices (at least as old as Roman times) of decorating pottery with "slip" and glass with "prunts"? Is it merely that, working in whichever material, it was equally natural to do what amounts to the same thing? Or is there anything to show that either potter or glass-worker was indebted to the other? I have seen it stated that the potter borrowed the idea from the glass-worker. Yet pottery is the more ancient art. Is there any evidence that one or other of them was first in the field?—GLASS-BLOWER.

Can anyone give me in short the genealogy of the Fleur-de-lis? If it begins as the Assyrian date-palm, by what stages does it become an iris, and when precisely does that turn into the lily of France?—ENTENTE CORDIALE.

I am interested to see that the subject of "Fire-walking" is receiving attention in the *Journal*. Like your correspondent "Maori," I have always been puzzled by this problem. I do not suppose anyone now doubts that in India as well as in Polynesia persons often walk harmlessly over yards of red-hot ashes. I can supply abundant testimony to the fact, apparently quite trustworthy, if desired. Could any of the learned members of this Society tell us how it is done? Has the problem been scientifically investigated?—W. Coldstream.

I have an ivory miniature, about 4¾" by 3¾", subject "The Music Lesson," with a cupid holding the music. The initials and date on it are E. E. 1700. Can anyone inform me who E. E. was? I have been quite unable to discover.—Torquay.

I have reeently purchased a large mill here which has some 300 horse-power of water-power from the River Derwent. It also has a very fine chimney about 160 feet high. Having regard to the large amount of water-power at my disposal, it is very unlikely that I shall make any use of the chimney for steam-raising purposes.

It has occurred to me to utilise this chimney as a shot tower for the manufacture of lead shot.

I have ascertained from the makers of shot-making plant that the chimney is very suitable, and the point I now wish to clear up is: What profit may one reasonably look forward to from the carrying on of the industry.

If you could furnish me with any reliable information on this point, I should feel extremely obliged.—Alf. R. Sennett.

ANSWER.

In reference to the note in the *Journal* of the 19th inst. about the ridding of grain from weevil, we desire to call your attention to the obvious disadvantage of bi-sulphide of carbon, *i.e.*, its great inflammability—this most dangerous property renders it practically prohibitive in the case of ships, whilst it is also extremely poisonous. On the other hand, sulphur dioxide, which is largely and regularly employed for this purpose, is compressed into a liquid, in which form it is supplied in various receptacles, from tins holding 12 oz. up to copper cylinders holding 2 cwt., and has been for a long time used for killing weevil in grain. None of the objections applying to bi-sulphide of carbon can be urged against pure sulphur dioxide gas, whilst the latter has the additional advantage of improving the colour of the grain.—A. Boake, Roberts, and Co., Ltd.

GENERAL NOTES.

Vienna International Shooting and Field-Sports Exhibition, 1910.—An International Shooting and Field-Sports Exhibition will be held in Vienna in 1910, which will include exhibits of all agricultural and trade products having any sort of connection with these matters. The object of the Exhibition is to show the amouut of economic profit to countries where hunting and shooting are encouraged, and the extent to which art, traffic, commerce, industry and trade are interested in the maintenance of those branches of sport, and the remarkably large profit which is derived from them, not only by the parties immediately interested, but also by the whole population. The Exhibition (which has the fullest support and co-operation of the Imperial and Royal Government and the Municipality of Vienna) will last about five months, from May till October, 1910. The general plan is that every State—including Austria—should have a separate space allotted to it, that the exhibits of each country should be displayed in a building or pavilion erected at that country's expense and representing either some famous historical shooting box or country seat typical of that country. The Exhibition will also afford an opportunity for holding International Hunting and Shooting Congresses, at which all the questions relating to these sports will be discussed.

The Feeble Minded and the Unemployed.—In considering the various causes of unemployment one not unimportant factor has received less attention than it deserves. Some ten years ago Parliament made it possible for education authorities to make day school and other provisions for mentally defective children. Since then special schools have been provided in which these children are taught, and to some extent, trained. London leads the way and many of the provincial towns have since followed its example. The number of defective children in the country is not as yet known with certainty, but Mrs. Mary Dendy, who has given much attention to the subject, considers the proportion to be not less than 1 per cent. of the school-going population. Heredity, drink, lack of nourishment, consumption, are among the reasons of their existence. What becomes of these weak-minded children after they leave the schools? When they leave school they are still mentally defective, but after they leave it, that is after sixteen, the law takes no further notice of them until they bring themselves again within its grasp as criminals, unemployed, or paupers. Mrs. Dendy says that two years ago they were leaving the London special schools at the rate of 800 a year. Many of them are only suitable for an asylum, but they are allowed to be at large and to become parents. They often get situations but they cannot keep them, for they are unstable and weak of will. Plainly the casual work of the mentally defective affects the work of all unskilled labourers. They take up odd jobs, and when working in gangs may do fairly well when pinched by necessity, but they cannot save against a rainy day, and seldom earn any wage that would enable them to save. Mrs. Dendy suggests that if there were special day schools for all the weak-

minded, and a colony to which to pass them on when they leave the day schools, the unemployable in the towns would soon be greatly lessened, and one of the greatest sources of physical deterioration would be removed.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

APRIL 21.—"The Foundations of Stained Glass Work." By NOEL HEATON, B.Sc., F.C.S. SIR WILLIAM B. RICHMOND, K.C.B., R.A., will preside.

APRIL 28.—"The Resources of the Peruvian Andes and Amazon." By C. REGINALD ENOCK, F.R.G.S.

MAY 5.—"English Furniture Design and Construction." By PERCY A. WELLS.

MAY 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S. The RIGHT HON. VISCOUNT MIDLETON, late Secretary of State for India, will preside.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

APRIL 6.—"Ceylon: its Industries and Material Progress." By JOHN FERGUSON, C.M.G. The RT. HON. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., will preside.

APRIL 20.—"South Africa." By the HON. CHARLES GIDEON MURRAY. LORD BRASSEY, G.C.B., D.C.L., LL.D., will preside.

MAY 18.—"Canada as a Field for British Investment." By J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

GEORGE GERALD STONEY, M.Inst.C.E., "Steam Turbines." Three Lectures.

LECTURE III.—APRIL 5.—The marine steam turbine—Early history—"Turbinia"—Comparative trials between reciprocating engine and turbine ships—Application to war ships—The great express Cunarders, "Mauretania" and "Lusitania"—Conclusion.

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

April 26, May 3, 10.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 5 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. George Gerald Stoney, "Steam Turbines." (Lecture III.)

Farmers' Club, Whitehall-rooms, Whitehall-place, S.W., 4 p.m. Mr. J. H. Diggle, "The Equipment and Cultivation of Small Holdings."

Engineers (in the Theatre of the United Service Institution, Whitehall, S.W.), 7½ p.m. Mr. Ernest R. Matthews, "The Corrosion of Steel-Reinforcement in Concrete."

Chemical Industry (London Section), Burlington-house, W., 8½ p.m. 1. Mr. Watson-Smith will Exhibit a Specimen of the now extinct Boghead Cannel Coal, or "Torbane Hill Mineral," and give a brief Historical and Chemical description of it. 2. Mr. S. Cowper Coles, "Vapour Galvanising." 3. Messrs. C. N. Hake and M. Bell, "The Action of Sulphuric and Nitric Acids in the Nitration of Cellulose."

Cold Storage and Ice Association, at the London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 7½ p.m. Mr. W. D. A. Bost, "Apparatus for Determining the Conductivities of Insulating Materials."

Victoria Institute, 1, Adelphi-terrace, W.C., 4½ p.m. Mr. C. A. Carus-Wilson, "Ezekiel's Vision of the Divine Glory."

TUESDAY, APRIL 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Mr. John Ferguson, "Ceylon: its Industries and Material Progress."

Asiatic, 22, Albemarle-street, W., 4 p.m. Dr. M. Moszkowski, "The Pagan Races of East Sumatra."

Alpine Club, 23, Savile-row, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. Arnulph Mallock's paper, "Construction and Wear of Roads." 2. Mr. C. T. Purdy, "The 'New York Times' Building."

Photographic, 66, Russell-square, W.C., 8 p.m. Messrs. C. E. Kennett Mees and S. H. Wainwright "Some Interesting Absorption Spectra."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Sir Lewis Michell, "Greater South Africa."

WEDNESDAY, APRIL 7...Royal Archæological Institution, 20, Hanover-square, W., 4½ p.m. Messrs. W. H. St. John Hope and Harold Brakspear, "Excavations at Haughmond Abbey in 1906."

Astronomical, Burlington-house, W., 5 p.m.

ERRATUM.—Dr. Nisbet asks that the following correction may be made in the text of his paper read last week, on page 390 of *Journal* for March 26th. 1909, column 2, lines three and four from top, *for* "£313,000 and £843,000, or £1,156,000 in all," *read* "£530,000 and £313,000, or £843,000 in all."

Journal of the Royal Society of Arts.

No. 2,942. VOL. LVII.

FRIDAY, APRIL 9, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURE.

On Monday evening, April 5th, Mr. GEORGE GERALD STONEY, M.Inst.C.E., delivered the third and last lecture of his course on "Steam Turbines."

On the motion of the CHAIRMAN (Sir William H. White, K.C.B., F.R.S.) a vote of thanks to the lecturer was unanimously passed.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

On Tuesday afternoon, April 6th, Mr. JOHN FERGUSON, C.M.G., read a paper on "Ceylon: its Industries and Material Progress." The Right Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., presided.

The paper and discussion will be published in the *Journal* on the 23rd inst.

INDIAN SECTION.

Thursday afternoon, March 25th; the Right Hon. LORD AMPTHILL, G.C.S.I., G.C.I.E., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that Mr. Thurston had been for many years the Curator of the Government Museum at Madras. In that, as well as in his personal and private capacity, he was held in the highest esteem, in fact he was known and respected throughout the whole of the scientific world. There was a story of him which illustrated better than anything else what manner of man he was. Mr. Thurston had the misfortune to lose most of his private means through a great bank smash, a calamity which he bore with a philosophic calmness which almost amounted to indifference; but when a little later a few ancient coins which were under his charge in the museum were stolen by one of the students or assistants, he was absolutely inconsolable, that apparently trifling loss affecting him infinitely more than the loss of his private fortune. The author was one of those men on whom the progress of science very much depended, and he was also one of the public servants who maintained the honour and power of the country in the distant parts of the Empire. It was well known that many of the great discoveries and triumphs of science had been due to men who disregarded every personal consideration — their health, safety, welfare, and comfort in the pursuit of science; and Mr. Thurston was such a man, because he put everything behind his duty as the curator of the museum and as a scientist engaged in research. A visit to the Government Museum at Madras was always a very pleasant experience, although at first alarming. Such was the author's zeal for anthropometry, that he seized every man, woman, or child in order to measure them. At first this scared people who did not know his ways, but they generally went away converted and flattered by some complimentary assurance that either the size of some part of their cranium, or the particular shape of their brain, or some other physical attribute was exceptional and admirable.

The paper read was—

NATIVE MAN IN SOUTHERN INDIA.

By EDGAR THURSTON,
Superintendent, Ethnographic Survey, Madras.

The vast tract of country over which my investigations in connection with the ethnographic survey of Southern India during the last eight years have extended is commonly known as the Madras Presidency, and officially as the Presidency of Fort St. George and its dependencies. Included therein are the Native States of Travancore and Cochin, and the smaller Feudatory States of Pudukōttai, Banganapalle, and Sandūr. Briefly, the task which was set before me in 1901 as Superintendent of the Survey was to record the manners and customs and physical characteristics

of more than 300 castes and tribes, representing more than 40,000,000 individuals, spread over an area exceeding 150,000 square miles, which is 30,000 square miles in excess of that of Great Britain and Ireland.

The five principal languages spoken in Southern India are Tamil, Telugu, Malayālam, Canarese, and Oriya. Of these, the first four belong to the Dravidian family, while Oriya, which is spoken in Ganjam and a portion of the Vizagapatam district, belongs to the eastern group of the Indo-Aryan family. In the preparation of the following brief summary of the other languages and dialects, I have drawn mainly on "The Linguistic Survey of India," and "The Madras Census Report, 1901."

Savara.—The language of the Savaras of Ganjam and Vizagapatam. One of the Mundā languages.

Gadaba.—Spoken by the Gadabas of Vizagapatam and Ganjam. One of the Mundā languages.

Kond, Kandhi, or Kui.—The language of the Kondhs of Ganjam and Vizagapatam.

Gōndi.—The language of the Gōnds, a tribe which belongs to the Central Provinces, but has overflowed into Ganjam and Vizagapatam.

Gattu.—A dialect of Gōndi, spoken by some of the Gōnds in Vizagapatam.

Kōya or Kōi.—A dialect of Gōndi, spoken by the Kōyis in the Vizagapatam and Godāvari districts.

Poroja, Parjā, or Parji.—A dialect of Gōndi.

Tulu.—The language largely spoken in South Canara (the ancient Tuluva). It is described by Bishop Caldwell as one of the most highly developed languages of the Dravidian family.

Koraga.—Spoken by the Koragas of South Canara. It is said to be a dialect of Tulu.

Bellera.—Spoken by the Belleras of South Canara, and regarded as a dialect of Canarese or Tulu.

Toda.—The language of the Todas of the Nīlgiri Hills, concerning which Dr. W. H. R. Rivers writes as follows*: — "Bernhard Schmid,† who wrote in 1837, appears to have known more of the true Toda language than any one who has written since, and he ascribes two-thirds of the Toda vocabulary to Tamil, and was unable to trace the remaining third to any other language. Caldwell‡ believed the language of the Todas to be most closely allied to Tamil. According to Pope,* the language was originally old Canarese, with the addition of a few Tamil words, but he has included in his vocabulary words which have probably been borrowed from the Badagas."

Kota.—A mixture of Canarese and Tamil, spoken by the Kotas of the Nīlgiri Hills.

Badaga.—The language of the Badagas of the Nīlgiri Hills. Said to be an ancient form of Canarese.

Irula.—Spoken by the Irulas of the Nīlgiris, and said to be a dialect of Tamil. Kasuba or Kasuva is recorded as a dialect of Tamil spoken by the sub-division of the Irulas which bears the same name.

Kurumba.—Spoken by the Kurumbas of the Nīlgiri Hills, Malabar and Mysore, and regarded as a dialect of Canarese.

Konkani.—A dialect of Marāthi, spoken almost entirely in the South Canara district by Sārasvat and Konkani Brahmans and Roman Catholics.

Marāthi.—In the Tanjore district, the descendants of the former Marātha Rājas of Tanjore speak this language. It is also spoken in the Bellary district, which was formerly under Marātha dominion, by various Marātha castes, and in the State of Sandūr.

Patnūli or Khatri.—A dialect of Gujarāti, spoken by the Patnūlkārans, who have settled for the most part in the town of Madura. They are immigrants from Saurāshtra in Gujarāt, who are said to have come south at the invitation of the Nayāk kings of Madura.

Lambādi.—The language of the nomad Lambādis, Brinjāris, or Sugālis. It is described in the Census Report, 1901, as a patois "usually based on one of the vernaculars, and embroidered and diversified with thieves' slang and expressions borrowed from the various localities in which the tribe has sojourned."

Korava or Yerukala.—A dialect of Tamil spoken by the nomad caste bearing these names. Like the Lambādis, they have a thieves' slang.

Vadāri.—Recorded as a vulgar Telugu dialect, spoken by a wandering tribe of quarrymen in the Bombay Presidency, the Behars, and elsewhere. They are doubtless Oddēs or Wudder navvies, who have migrated from their home in the Telugu country.

The population of Southern India may be roughly divided into long-heads and round-heads, of whom the former prevail in the Tamil

* The Todas, 1906.

‡ "Comparative Grammar of the Dravidian Languages."

* Outlines of the Toda grammar appended to Marshall's "Phrenologist Among the Todas."

country and Malabar. I cannot here enter into a discussion of the influences which have brought about the marked difference, shown in the following Table, in the type of cranium in the northern and southern portions of the area under consideration; and must content myself with the bald observation that, whatever may have been the influence which has brought about the existing mesaticephalic or sub-brachycephalic type, with high cephalic index, in the north, this influence has not extended southward into the Tamil and Malayālam countries, where Dravidian man remains dolicho- or sub-dolichocephalic.

Class.	Language.	Cephalic Index.
Sukun Sāte	Marathi	82·2
Vakkaliga	Canarese	81·7
Billava	Tulu	80·1
Rangāri	Marathi	79·8
Agasa	Canarese	78·5
Bant	Tulu	78·
Kāpu	Telugu	78·
Golla	Telugu	77·5
Pallan	Tamil	75·9
Mukkuvan	Malayālam	75·1
Nāyar	Malayālam	74·4
Vellāla	Tamil	74·1

A character, with which I am very familiar, when measuring all sorts and conditions of Natives in Southern India, is the absence of convexity of the segment formed by the posterior portion of the united parietal bones. The result is that the back of the head, instead of forming a curve gradually increasing from the top of the head towards the occipital region, forms a flattened area of considerable length almost at right angles to the base of the skull. This character is shown in a marked degree in the photograph exhibited, which represents a prosperous Linga Banajiga in the Canarese country.

The Linga Banajigas are a trading section of Lingayats, who are a religious sect, abounding in the Canarese country, whose distinctive characteristic is the wearing of a linga—the symbol of the god Siva—made of steatite, or soapstone, and enclosed in a metal casket, often of silver, and sometimes encrusted with precious stones, or, among the poorer classes, enclosed in a cloth of a particular colour. The linga should always be worn, both by males and females, and is buried with the corpse. A Lingayat shopkeeper, who was not wearing it, explained that he removed it during working hours, as it was necessary to tell a little lie when doing business. The linga is worn on various parts of the body—the head, arm, chest, and waist. Sometimes, in addition to the linga, a rosary of rudrāksha beads is worn as a necklace. In connection with the rudrāksha, the legend runs that Siva or Kālāgni Rudra, while engaged in Tripura Samhāra, opened his third eye, which led to the destruction of the three cities, of which Rākshasas or Asuras had taken the form. From this eye liquid is said to have trickled on the ground, and from this arose the rudrāksha tree (*Elæocarpus Ganitrus*). The mere mention of the word rudrāksha is believed to secure religious merit. Rudrāksha beads are valued according to the number of their lobes (or faces, as they are called), which are usually five in number. A bead with six lobes is believed to be specially good, and one with two lobes, called Gauri sankara rudrāksha, is very highly valued. Dikshitar Brāhmans wear a two-lobed bead mounted in gold.

Among the Arādhya Brāhmans, who wear both the sacred thread and the linga, the popular belief is that if, by some accident, the linga is lost, an individual must either fast until it is recovered, or not survive so dire a calamity. The linga is the life of him who wears it, and, when he loses it beyond recovery, he loses his own life. Incredible stories are told of miraculous recoveries of the linga. In one case, it is said to have returned to its owner, making a loud noise in water; and in another it was found in a box under lock and key. In this connection, the following story is narrated by Colonel Wilks:—* "Poornia, the present Minister of Mysore, relates an incident of a Lingayat friend of his, who had unhappily lost his portable God, and came to take a last farewell. The Indians, like more enlightened nations, readily laugh at the absurdities of every sect but their own, and Poornia gave him better counsel. It is a part of the ceremonial preceding the sacrifice of the individual that the principal persons of the sect should assemble on the bank of some holy stream, and, placing in a basket the lingam images of the whole assembly, purify them in the sacred waters. The destined victim, in conformity to the advice of his friend, suddenly seized the basket, and overturned its contents into the rapid Caveri. 'Now, my friends,' said he, 'we are on equal terms; let us prepare to die together.' The discussion terminated according to expectation. The whole party took an oath of inviolable secrecy, and each privately

* "Historical Sketches of the South of India."

provided himself with a new image of the lingam."

The Lingayat priests are called Jangams, some of whom are religious mendicants. One of the latter, whom I saw at Sandūr, was clad in very elaborate begging attire, which included sandals studded with blunt nails. On one occasion a friend came across a man sitting in the verandah of his house, from within which groans proceeded. It was explained that his wife was swinging on a swing studded with sharp nails, to cure him—by sympathetic magic—of some trifling ailment.

Some Pandāram mendicants wear the linga in a casket, and have an apparatus consisting of iron triangles round the neck in performance of a vow. When proceeding on a pilgrimage to the Temple of Subramaniya Swāmi at Palni, some devotees pierce their cheeks with a long silver needle, which traverses the mouth cavity; pierce the tongue with a silver arrow, which is passed vertically through the protruded organ; and place a silver shield (mouth-lock) in front of the mouth. Some Dāsaris (Vaishnavite mendicants) have permanent holes in their cheeks, into which they insert the needle when they go about the country in pursuit of their profession.

I turn for a few moments to a consideration of the various peoples, past and present, in Southern India. The pre-historic inhabitants are abundantly represented by tumuli, cairns, cromlechs, palæolithic, and neolithic implements, pottery, &c. Pre-historic stone celts are believed by the Malaiālis of the Shevaroy Hills to be the thunderbolts of Vishnu, and are stacked as votive offerings in their shrines dedicated to Vignēswara, the elephant god who averts evil. The Burmese believe that, when the powers above quarrel, they throw celts at one another, and that, when one misses, it falls to the earth. They attach considerable importance to them for medicinal purposes, and powdered celt is said to be equally good for a pain in the stomach or an inflamed eye. The cromlechs on the Nīlgiri Hills are believed to have been built by a race of pygmies, assisted by hares and porcupines. In like manner, the big earthen burial urns, which are found in many parts of the country, are believed to have been made for a race of pygmies, or for the disposal of old women who would not die. Some Khōnds in Ganjam wear blue beads and cut agates, which are said to be dug out of ancient burial places in Central India.

The most archaic type of existing man is represented by the jungle or forest tribes, the microscopic remnant of an ancient race, living in the seclusion of the jungle, where they have more or less retained their racial purity, which is disappearing as the result of contact metamorphosis from communication with the outside world. They are short of stature, dark-skinned, and broad-nosed (platyrhine), and have nothing in common with the tall, hairy, and narrow-nosed (leptorhine) Todas, who inhabit the Nīlgiri plateau. The Todas live in picturesquely situated settlements, called mads or mands, breed a large-horned race of buffaloes, and practice the form of polyandry, in which the husbands of a woman are own brothers. "There is," Dr. Rivers writes,* "no doubt that, in former times, the polyandry of the Todas was associated with female infanticide, and it is probable that the latter custom still exists to some extent."

In former days, the Kondhs of Ganjam practised female infanticide, in the belief that the sun god, in contemplating the deplorable effects produced by the creation of feminine nature, charged men to bring up only as many females as they could restrain from producing evil to society. It was possible to come across villages, in which there was not a single female child.

The main bulk of the population is represented by the Dravidians of the plains, and, in addition, there are the Brāhmans. It is, I believe, a common idea among Anglo-Indians, that the Brāhmans alone wear the sacred thread, with which they are invested at the upanayana ceremony. This is, however, by no means the case. For example, the thread is worn by the Patnūlkārans, an extensive and go-ahead colony of weavers at Madura, who claim to be the descendants of Saurashtra Brāhmans, who migrated southward from the Saurashtra country in Gujarat. The thread is also worn by the Kōmatis, a clan of Telugu traders, who claim to be Vaisyas—the third caste of Manu. The Kōmatis have a quaint marriage custom, and one from which their families derive their distinguishing names. The figure of a cow is made of flour, and into the stomach is put a mixture of turmeric, lime, and water. After the cow has been worshipped in due form, it is cut up, and to the different families is sent that portion which they are entitled to receive, one getting the horns, another the neck or

* "The Todas," 1900.

hump, and so on. The sacred thread is also worn by the Kammālans or artisan class, who claim to be descended from Visva Karma, the architect of the gods, and to be Visva Brāhmāns, calling the true Brāhmans Gō or Cow Brāhmans. By some Kammālans of Malabar the adelphic form of polyandry is practised. It is said that a girl may have a series of brothers, ranging in age from five to twenty-five, whom she has to regard as her husbands. The Malabar Kammālans boast that their system of polyandry is the result of the sojourn of the exiled Pāndavas, with their common wife Panchali, and their mother Kunthi, in the forests of the Valluvanād division of Malabar.

Civilisation is fast bringing about changes in manners and customs, which are sad from the ethnographist's point of view. The Shānan females, like those of some other castes in the Madura and Tinnevelly districts, have the lobes of their ears dilated by a process of gradual dilatation from infancy. A Tinnevelly missionary was an expert at removing the deformity among his converts to Christianity by operative surgery. The converts at first objected to the operation, as the shortened lobes made them look like Dēvadāsis or dancing girls, whose morality is notoriously frail. Altercations between Kallan women constantly lead to one or both parties having the dilated ear-lobes, which reach down to the shoulders, violently torn asunder. It is stated, in the Gazetteer of the Madura district, that "even at the present day, in quarrels between women of the lower castes, long ears form a favourite object of attack, and lobe-tearing cases figure frequently in police records."

Females of many castes on the west coast go about nude down to the waist. But the custom of covering the upper part of the body with a kind of towel, as a more elaborate garment, is fast gaining ground. When I was inspecting a jungle tribe in South Canara, females, young and old, removed the cotton wrapper from their chests as I passed down the line. Here the upper garment, by a reversal of Western ideas, indicated immodesty. And it is not the feeling of shame that has given rise to the covering of the body, but the covering that has provoked the feeling of shame.

Leafy garments, representing the fig leaf stage of society, are fast disappearing. Such garments, or aprons, are still worn by the Thanda Pulayans of the Cochin State. They are made from the thanda sedge, and put on, when a girl reaches maturity, with a formal ceremony called thanda kalyānam (marriage). The wearing of this garment is accounted for by a tradition that "a certain high caste man had been sowing grain and planting vegetables in his fields, but found that his daily work was in some unknown way frustrated. For whatever he planted or sowed in the day was carefully picked up and taken when men slept. So he set a watch, and one night he saw coming out of a hole hitherto unknown to him certain beings like men, but quite naked, who set to work destroying his hopes of a crop. Pursuing them, he succeeded in catching a man and a woman, and he was so ashamed of their condition that he gave the man his own upper cloth; but, not having one to spare for the woman, she (following mother Eve's example) made herself an apron of grass*." The jungle Vettuvans, of Malabar, wear aprons of leaves stitched together. The origin of this gear is said to be that, when the god Paramēswara was distributing gifts of clothing to the various peoples of the earth, he asked the Vettuvans whether they would prefer a daily or yearly change of apparel. They decided in favour of the former, and the god, to punish them for their ambition, decreed that their daily dress should consist of leaves. They change, or should change, their foliage every day at noon. A festival, which is attended by huge crowds, takes place annually at the village of Periyapalayam, near Madras, where the goddess Mariamma is worshipped under the name of Periyalayathamman. Those who attend are under a vow to wear a garment made of leafy twigs of the nīm or margosa tree (*Melia Azadirachta*), which is purchased from hawkers, who do a brisk trade. Those who belong to the more respectable classes go through the ceremony in the early morning, before the crowd has collected in its tens of thousands.

The primitive jungle man is now attempting to raise himself in the social scale, adorns his forehead with a quasi sect mark, made with ashes or tinned aniline dye, shaves his head in imitation of the Hindus, and smears his body with sandal paste in mimicry of his superiors.

Lucifer matches are now replacing the making of fire by friction, or flint and steel. The Todas of the Nīlgiris did not object to lighting the cheroots, which I gave them, with matches. But they must light the fire by

* Rev. W. J. Richards, Ind. Ant. ix., 1880.

friction at some of their daily ceremonies, and at the funerals of males. At the funeral of a Toda female, I myself supplied the matches for lighting the pyre. A fire stick, which was in current use in a Toda dairy, was polluted, and rendered useless by the touch of my Brāhman assistant! Among the Nambūdiri Brāhmans of the West Coast, the sacred fire for sacrifices should be produced by the friction of two pieces of wood. And, during their marriage rites, fire is made with pieces of wood of the jak tree (*Artocarpus integrifolia*) and pipal (*Ficus religiosa*).

A ceremony, called hook-swinging, is now viewed with disfavour by Government. Some years ago a man in a village north of the Godavari river, who had four holes in his loins from previous swingings, complained to the Deputy Commissioner that his occupation was gone, as he was no longer allowed to be swung. During one of the tours of a recent Governor of Madras, the villagers complained that, since the practical abolition of hook-swinging, the rainfall had been deficient, and the crops scanty, cholera had been prevalent, and the child-bearing capacity of the females had diminished. There is a legend that in a fight between the goddess Kāli and the demon Darika, the latter was completely defeated, and the former, biting him on the back, drank his blood to gratify her feelings of animosity. Hook-swinging symbolises this incident, and the blood shed by the insertion of the hooks through the flesh of the back is intended as an offering to the goddess. In cases of famine, cholera, or other calamity, a swinging festival used to be held, for the purpose of propitiating the deity, and, at the same time, a sacrifice of goats, sheep, pigs, fowls, and even male buffaloes, took place. As human hook-swinging is forbidden, a substituted ceremony is sometimes performed. Such a ceremony was gone through for my edification at the shrine of Mariamma at Chennapatna, in the Mysore Province. The goddess borne by a priest, and a little wooden figure of Sidi Vīranna carried by a boy, were worshipped at a tank (pond), and brought in procession to the scene of the swinging ceremony. To a long beam, Sidi Vīranna, dressed up in a gaudy turban and silk-bordered cloth, and carrying in his hands a sword and shield, was secured by means of a rope of human hair, which was tied to a hook in the middle of his back. The beam was then hoisted on high, and Sidi Vīranna was rotated round and round. Sometimes a cradle is tied to the beam, and children are swung in performance of a vow. And occasionally men, tied to the beam by ropes round the waist, are hoisted.

Turning now to the jungle tribes, let me correct a statement which is sometimes made that they are woolly-haired. Curly hair abounds, but woolly hair is never found. As a typical example of the physical characteristics of these tribes, who are represented by Paniyans, Kurumbas, Shōlagas, Irulas, and others, I may cite the Kādirs of the Anaimalais (Elephant Mountains) in the Coimbatore district. These Kādirs are excellent hands at climbing trees by means of pegs driven in with a bill-hook. The method of climbing is exactly the same as that in vogue among the Dyaks of Borneo, as described by Wallace in his "Malay Archipelago." And, like some Malay tribes, *e.g.*, the Semangs, the Kādir females wear a bamboo comb in the hair, ornamented with a design which corresponds very closely with the design on the combs worn in the Malay Peninsula. It is noted by Skeat and Blagden* that the Semang women wore in their hair a remarkable kind of comb, which appears to be worn entirely as a charm against diseases. I am informed that the Kādir combs are not looked on as charms, and the markings thereon have no mystic significance. A Kādir man should always make a comb and present it to his wife just before marriage, or at the conclusion of the marriage ceremony, and the young men vie with each other as to who can make the nicest comb. The Kādirs, like some tribes in the Malay Peninsula, have some of their teeth chipped. In the Malay Peninsula, the common way of expressing the fact that a girl has reached marriageable age is that she has had her teeth filed. The operation of chipping the teeth is performed by the Kādirs with a chisel or bill-hook and file, and carried out on both males and females at about the age of puberty. In their search for honey, the Kādirs will only remove the hives during dark nights, as the darkness gives them a feeling of security in descending a precipice by means of a fragile rope ladder. As a guarantee of their safety, they take care that their wife or son watches above, to prevent a possible enemy from letting the ladder go. And sometimes they take with them the wife of the man who is in charge of the ladder above.

The Pulayans, who inhabit the jungles at

* "Pagan Races of the Malay Peninsula. 1900."

the base of the Tinnevelly Hills, are the most unpromising specimens of dejected humanity whom I have come across. Some missionaries once attempted to conciliate them by means of a feast. When summoned to the banquet which had been prepared for them, they retired much offended, as with the food were put betel leaves and tobacco, which were of evil omen, as these articles are offered at the grave on the occasion of a funeral. I cite this incident as an example of the ignorance of the habits and superstitions of the Natives, which sometimes leads to unfortunate mistakes by those responsible for Indian administration. And I am in entire sympathy with the recent memorial, urging, *inter alia*, that selected candidates for the Indian Service should be required to take a course of study in the ethnology, sociology, and religion of the races among whom their life-work will lie.

The Ulladans of Travancore are, so far as I am aware, the only tribe who use a cross-bow. The existence of this weapon puzzled me until the word Feringhi, meaning Frank or European, was used in connection with it, and it is doubtless of Portuguese origin. Many Portuguese names still survive among Eurasians and Native Christians on the west coast, and a recent telegram, "Da Gama taking leave. Proposed that Albuquerque officiate for him," has an old time ring about it.

The jungle tribesmen depend, for shooting animals and birds for food, on bows and arrows, with barbed or blunt heads. At a long distance shooting match among the Chenchus of the Nallamalai Hills, the prize was won with a carry of only 144 yards. We have it, on the authority of a celebrated archer of Charles I., that the ordinary range of the bow was from sixteen to twenty score yards. A Chenchu, who gained the prize in a shooting match, with the face of a straw scarecrow as bull's-eye, was in an advanced state of intoxication, and naively used his success as an argument in favour of drink. It was noted by Captain Newbold that the Chenchus are not remarkably expert as archers, to judge from the awkwardness they exhibited in dispatching an unfortunate sheep picketed for them at forty yards, which was held out to them as the prize for the best marksman. Some time ago a Chenchu, who was the bully of his settlement, beat another Chenchu and his wife. The injured man appealed to the District Forest Officer, and, explaining that he knew the law did not allow him to kill his enemy, applied for a written permit to go after him with a bow and arrow.

The visual acuity of the Chenchus was tested with Cohn's letter E, No. 6. The visual acuity is represented by a fraction, of which 6 is the denominator, and the number of metres at which the letter was recognised by the individual tested is the numerator, *e.g.*,

$$V.A = \frac{13\,m}{6} = 2{\cdot}16.$$

The average distances in metres at which the letter was recognised by the various castes and tribes examined by myself and Dr. Rivers were as follows :—

16 Shōlagas (Rivers)	12·9
94 Kotas	12·8
180 Badagas	12·6
50 Paraiyans	12·5
58 Telugu ryats	12·4
28 Chenchus	12·3
55 Urālis (Rivers)	12·2
30 Brāhmans, Mysore	12·2
30 Non-Brāhmans, Mysore	12·2

In all classes, it may be noted, the average acuity was between 12 and 13 metres (13 to 14 yards), and ranged between V.A = 2·15 and V.A = 2·03. The maximum distances at which the position of the letter was recognised were : —Shōlaga, 18m.; Paraiyan, 19m.; Badaga and Dikshitar Brāhman, 20m. The nine classes, or groups of classes examined, cover a wide range of degrees of civilisation, from the wild jungle Chenchus, Shōlagas, and Urālis to the cultured Brāhman. And, though the jungle man, who has to search for his food and mark the tracks and traces of wild beasts, undoubtedly possesses a specially trained keenness of vision for the exigencies of his primitive life, the figures show that, as regards ordinary visual acuity, he has no advantage over the more highly civilised classes.

On the occasion of a Viceregal visit to Travancore, the Kānikars constructed an elaborate "tree house." They are very expert at building huts in trees, called ānamadam (elephant huts), for watching the crops, and driving away marauding wild beasts, such as pigs and elephants. The huts are made of bamboo thatched with jungle leaves, and a crude bamboo ladder connects them with the ground. When all the inmates are safely housed for the night, the ladder is removed aloft out of the reach of elephants, who, mischievously inclined, might remove the obstruction, and leave the Kānikars to regain *terra firma* the best way they can.

The Gadaba women of Vizagapatam wear a bustle or dress-improver made of fibre. This article of attire is accounted for by a tradition that a goddess visited a Gadaba village *incognita*, and asked leave of one of the women to rest on a cot. She was brusquely told that she must sit on the ground. It was ordained that thenceforth all Gadaba women should wear a bustle to remind them that they should avoid churlishness. The Gadaba females also wear cloths manufactured from cotton thread and fibre. According to a legend, when Rāma, during his banishment, was wandering in the forests of Dandaka, his wife Sīta accompanied him in spite of his entreaties to the contrary. It was one of the cruel terms of his stepmother Kaika that Rāma should wear only clothing made from jungle fibre, before leaving the capital. According to the Hindu religion, a virtuous wife must share both the joys and sorrows of her lord. Consequently Sīta followed the example of Rāma, and wore the same kind of clothing. They then left the capital, amidst the loud lamentations of the citizens. During their wanderings they met some Gadaba women, who mocked and laughed at Sīta. Whereupon she cursed them, and condemned them to wear no other dress but the cloth made of fibre.

DISCUSSION.

Sir WILLIAM LEE-WARNER remarked that Mr. Thurston's interesting and able paper, with its excellent illustrations, possessed a double value, for the historian of the past and for the statesman who had his part to play in the present. The materials for Indian history were so scant that the chips from the workshops of every man of science were of the greatest importance. One explorer brought a coin, another an edict graven on stone, a third interpreted architecture, and a fourth cut into a tumulus, and now the lecturer had shown that the human remains discovered in sepulchral jars might help us to say what manner of man once carried that skull and whence he came in the migrations of old time. All these threads helped to guide us to some knowledge of the men of old, their habits, and their lives. Chiselled teeth, a round or a long head, these and other hints enabled the anthropologist to confirm or correct the theories based on pottery, art, or architecture. But perhaps the most important lesson which the paper suggested was that which the administrator of India might learn, and this led the author to recommend that the selected candidates for the Civil Service should be instructed in anthropology. The camel, however, could not bear more than a certain load. In his year of probation the civilian, exhausted by the strain of competition and his University studies, could only go through a limited course, and languages, law, and other subjects must be his first care. But there were others in this country who were more and more using their positions to control and direct Indian administration. On them such a paper as they had just heard might exercise a salutary influence. It might give pause to theorists who looked upon the peoples of India as one nation, or on the requirements of her various races as simple and uniform. It might be well if our legislators could have seen the types of large sections of the Indian community which had been thrown on the screen and drawn their own conclusions. The Indian Section of the Royal Society of Arts was endeavouring to provide in each season one or more papers upon the various classes and sections of the Indian population, and Mr. Thurston's contribution to the series would be regarded as one of high value by those who had had the pleasure of hearing it and seeing the photographs that so clearly illustrated the paper.

Sir JAMES THOMSON, K.C.S.I., said that while the paper, like the author's numerous and famous reports, contained excellent anecdotes and information, which were very entertaining and scientific in their way, it did not contain exactly what he was most in search of. Being a busy man, he wished to be provided, at short notice, with cut-and-dried judgments or conclusions on the subject, something for immediate use. With regard to the matter of hook-swinging, he remembered thirty-seven years ago, when quite a young man, straying into a village in the district of South Arcot, and finding a festival in active operation. The unfortunate man had the flesh of his back softened by the instrument to which Mr. Thurston referred, and the hooks were then inserted, one on one side of the back and the other on the other. He remembered feeling very uncomfortable when he saw the blood trickling down the man's back, although the man seemed perfectly happy. He had never had the good fortune to see the Periyapalayam festival during its progress; but he could not help feeling sorry for the destruction of the large quantities of twigs of the nim tree which were used in decorating the people. He was inclined to agree with the author that it would be a most excellent thing if the young men who went out to administer the British Empire in the East, and even those who engaged in ordinary industrial pursuits, received a training in the sociological and ethnological characteristics of the people amongst whom their life's work was to be passed, but, at the same time, he thought it would probably be better carried out in India than at home.

Sir ARUNDEL T. ARUNDEL, K.C.S.I., agreed with Sir James Thomson's remarks with regard to

the training of men for the Indian Civil Service, although he had not sufficiently studied the subject to put forward definite suggestions. He also agreed with Sir William Lee-Warner's plan of educating Members of Parliament on Indian affairs.

The CHAIRMAN proposed, and Sir WILLIAM LEE-WARNER seconded, a hearty vote of thanks to Mr. Thurston for his interesting paper.

The resolution was carried unanimously.

Mr. THURSTON, in reply, thanked the Chairman for adding another to the many acts of kindness he had shown him while in Madras by presiding over the meeting. His lordship had referred to a trifling monetary loss which he (Mr. Thurston) sustained in a bank smash. Although he did lose a certain amount, he did not lose the whole of the vast fortune which an Uncovenanted Indian official was able to save out of his income, but he thought the state of his feelings at that time and on the occasion of the loss of the coins was sacred to the Club Bar at Madras. Sir William Lee-Warner had referred to his remarks on the subject of training the suckling administrator. Before going back to India he was thinking of taking his discourse down to Cambridge, and inflicting it on the undergraduates there, because they were the men who must be instructed. Sir William Lee-Warner occupied a high position of responsibility, and if that gentleman could arrange matters, he (Mr. Thurston) was perfectly prepared to take his discourse, lantern slides and all, and deliver it before the members of either the House of Commons or the House of Lords! Sir James Thomson, a great friend of his, had charged him with having reached the melancholy stage of anecdotage. He could have dealt with the subject of the paper in two entirely different manners. In the first place, he could have given a great many statistics and technical details, or he could treat the subject in a more popular fashion. He had thought it better to adopt the latter course, as more suitable to a general audience. He had a standing invitation to visit Sir James Thomson at his house, and when he did so he was prepared to puzzle him by discussing anthropological problems with him.

THE COST OF LIVING IN FRENCH TOWNS.

The Board of Trade has followed up its investigations in the cost of living to the working classes in towns of the United Kingdom and Germany, by a similar investigation of thirty French towns, inhabited by people occupied in all sorts of industries. The result of the enquiry is a valuable collection of facts, but it is very necessary to bear in mind the observation of the report itself, that "International comparisons of this nature are full of difficulties arising from differences of national habits and tastes, and from varieties of national organisation, and therefore comparisons based on statistic data alone, must always be read as subject to limitation by conditions which it is impossible to measure statistically." There is abundant proof in this Blue-book of the great difficulty of making trustworthy comparisons between England and a foreign country, in these matters. For example, the report gives prominence to the large percentage of the French working-classes who live in a single room, as compared with the same classes in England and Germany. The tables show that, while in England and Wales dwellings of four and five rooms are the most usual amongst the working-classes, and in Germany dwellings of three rooms, in France tenements of two and three rooms are equally frequent, and tenants of a single room, which were not of sufficient importance to tabulate either in England or Germany, are characteristic of working-class housing in more than half the French towns visited; but in considering this statement two facts have to be borne in mind: the most typical sizes of rooms occupied by working-class families in England and Wales lie between 100 and 150 square feet in area, whereas in France they are between 120 and 200 square feet, and whereas the French rooms are considerably larger than the English, the French household is much smaller. But the difference of accommodation is relatively greater than the difference in the size of the household would warrant, and the smallness of the number of children cannot serve entirely as an explanation of the large number of single room dwellings. Take again the question of house rent, which is such a vital item in the English workman's budget. The figures quoted show that French rents are much lower than English. They are just over three-fourths of the rents of London tenements, but whilst in England the landlord usually pays the rates and recoups himself from the tenant, the rates being approximately 18 per cent. of the gross rent paid in English industrial towns, the French tenant does not as a rule appear to include any element of local taxation, nor has he to pay water rate, as water appears to be freely available to him as a rule, even though it may have to be fetched from the street. If local taxation be excluded from both sides of the account, the Frenchman pays about 2 per cent. less than the Englishman for the same number of rooms.

As to wages and hours of labour, the French workman would appear to be at a distinct disadvantage as compared with Englishmen. Judging by the policy of wages agreements, *i.e.*, agreements made between employers and employed, and established for a particular industry throughout a prescribed area, the rates of wages seem to have made little progress in France, a fact which is probably due to the comparative weakness of trade unionism in most of the towns.

But it is quite plain from the information collected that the Frenchman works longer hours for smaller pay than the Englishman. The report estimates that, taking the building trades, engineering trades, and printing trades, the hours of labour of the French artisan are from 13 to 23 per cent. higher than the hours of labour usual in this country amongst corresponding classes of workpeople. The weekly wages in France for the trades considered stand to English weekly wages for the same trades approximately as 75 to 100, the corresponding ratio for Germany being 83 to 100. The comparison is based on a limited number of trades only, so that there is room for doubt as to how far the conditions in such trades may be taken as generally typical of the conditions in France; but, while it is not possible to make exact comparisons of wages in other trades, the data given in the detailed reports tend to confirm the general impression that rates of wages are, with few exceptions, relatively low in France.

On the whole the Frenchman seems to feed himself better than the Englishman. Taking a man with a weekly income of 25s. and under 30s. in the United Kingdom, 3s. 4d. of it would go on food and drink per head, excluding alcohol; in Germany 3s. 9d., in France 4s. 3d. Considered as a whole, the dietary of a French working-class family is much more varied than that of the British family possessing the same income, and when allowance is made for the smaller number of children in France it is also relatively greater in quantity. The *per capita* consumption of bread, of meat and and fish, of eggs, of butter and other fats, and of potatoes, is distinctly higher, and of all vegetables and fruit very much higher than that shown by the British Budget, while that of milk is slightly higher. Sugar is the only item of which the consumption is much less in France than in England.

The conclusion arrived at by the report is that if the prices of rents in England were changed to their respective levels in France, the expenditure of the average British artisan would need to be increased by nearly one-seventh to enable him to maintain the same standard of life. The weekly money wages of the working-classes in the trades it has been possible to compare with similar ones in England are as 75 to 100; the average usual working hours as 117 to 100; and the hourly rates of money wages as 64 to 100. The basis of this estimate, however, is limited by the fact that the wages and hours of labour which it was possible to compare were only those of the various sections of the building and engineering trades and one section of the printing trade. It must also be remembered that the comparison of prices could not be extended to all the items of the British Budget, and that the comparison of food prices is made from the standpoint of the British artisans' ordinary dietary and not from that of the French dietary. The cost of the ordinary French family budget at French prices will not bear to its cost at English prices so high a ratio as 118 to 100.

THE INDUSTRIES AND RESOURCES OF EASTERN BENGAL AND ASSAM.

A very exhaustive report on the above subject has just been issued from the Shillong Government Press. It is from the pen of Mr. G. N. Gupta, M.A., of the Bengal Civil Service, and contains a detailed review of the various industries of the province, concluding with a summary and suggestions for their improvement and development. The industries themselves are too numerous to specify, but they may be briefly classified as consisting of textile, metal, and leather industries; carpentry, pottery and earthenware; artistic handwork; and agricultural, forest, fish, mineral and miscellaneous industries. When we mention that the above review covers a hundred closely printed foolscap pages, its elaborate nature will be understood. From a practical point of view interest naturally centres on the summary and recommendations for reform, and in approaching this part of the subject, the author makes some preliminary remarks of importance. The indigenous industries of India are decadent, and those which have sprung up instead during the last twenty years have been promoted by foreigners with imported capital, and the profits are remitted abroad. The management and direction are not in Indian hands, and no fund of experience is being accumulated in the country to enable further progress to be made. Among the chief reasons which militate against large industrial enterprise being undertaken by Indians may be mentioned the insufficiency of fluid capital and the want of trained labour. For some time to come such Indian capitalists in Eastern Bengal and Assam as do come forward are recommended to get expert supervision from more advanced parts of India, or, better still, engage properly qualified and competent Europeans.

The province itself is one of the least advanced, so far as industrial progress is concerned. There are no cotton-weaving mills worthy of the name, no cotton-spinning mills, no jute-manufacturing mills, neither wool nor paper mills, glass factories nor pottery works. The exports of the province are also all in raw materials; there are no large industrial centres—like Madras, Cawnpur or Calcutta—and out of the sixty-two larger towns of India, East Bengal and Assam possesses only one (Dacca) with a population of over 50,000 souls. There is a discouraging increase of opium consumption among the indigenous population of Assam, and even agriculture is not very flourishing there. Eastern Bengal is by far the most progressive part of the province; the majority of the population are Mohammedans, and a virile and strongly constituted race, while among its Hindus are to be found some of the most skilful artisans in the whole of India. Here, thanks to jute and the natural advantages of the land, agriculture is in a more prosperous state than elsewhere in India. There is, however, a general desire on the part of the people to encourage and patronise their own manufactures, as well as a desire on the part of moneyed

people, and the middle classes, to engage in industrial enterprises. As to the advent of the literary classes in the field of industry, the following remarks by Mr. Gupta are worth quoting:—"When I saw two young men, who had both passed the entrance examination, going through all the dirty manual work of unhairing leather in a Dacca factory, I was very agreeably surprised. A hosiery firm in Dacca is being worked by a young graduate, whose father is a well-to-do pleader. In Bogra, I met with a graduate who had settled down comfortably as a dealer in rice and jute. The new industry of button-making in Dacca is being largely pursued by men of the higher castes."

Taking the situation as a whole, the outlook is by no means discouraging, especially when one bears in mind, in addition to the foregoing facts, the mineral and agricultural resources of the province, and the various waterways and other communications which afford facilities for trade.

The chief recommendation for improving the present state of things consists in the creation of a separate department to deal with industrial questions and control technical education, a course which has been already adopted in Madras, Bombay, and by other Local Governments. The functions of the department will be, broadly speaking—(1) educational, (2) commercial, and (3) administrative. Its educational duties will be to organise and maintain a system of central and local technical and industrial art institutions in the province; its commercial functions will be to pioneer new industries, and by rendering financial assistance, and by other means to encourage private enterprise; while its administrative functions will consist in the difficult task of securing a co-operation of the people by the creation of industrial committees or bureaux, or similar institutions, and in the establishment of co-operative credit societies among the artisans. Government, it is suggested, should actually pioneer some selected new industries, as has been done in Madras, and (to go further afield for an example) in Japan. In the last-named country after the Restoration, the new Government systematically encouraged the use of Western methods, setting the example by establishing a model filature, a silk spinning mill, a woollen factory, a cotton spinning mill, a cement factory, a glass factory, a paper mill, and other model workshops, besides lending money for the purchase of the necessary plant. In time, as these enterprises were taken up by private individuals, the Government began to sell its own factories.

The most promising future industries in Eastern Bengal and Assam would appear to be—(1) The tanning of leather and manufacture of leather goods; (2) the manufacture of sugar; (3) power mills for silk weaving; (4) power mills for spinning and weaving cotton; (5) tobacco manufacture; (6) match factory; (7) paper mill; and (8) lac factory. Besides these there are numerous other industries of a somewhat minor importance, including such items as enamelled ware, glass, soap, tiles, and preservation of vegetables and animal products; regarding these careful inquiries might be made, and if favourably reported on, they might be set on foot experimentally.

Mr. Gupta concludes his report with several extracts from the speeches of Sir Arthur Lawley and the more elightened leaders of native Indian opinion, all tending to prove that the Swadeshi movement has been running on the wrong lines, that boycott by itself can never solve an industrial problem, and that the realisation of political ideals is to a great extent, if not wholly, dependent upon India's progress as a nation in the paths of useful knowledge, industry, and commerce, as well as co-operation.

ARTS AND CRAFTS.

Exhibition of Work from London Technical Institutes.—It is a good plan to show from time to time the work executed in the various technical institutes aided by the London County Council, and the Whitechapel Art Gallery is in many ways an excellent place for the exhibition. If its lighting arrangements are better suited for pictures than for craft work, it is still possible to see most of the exhibits fairly easily, and its topographical situation is admirable—not too far east to be accessible to people who live in the west and yet on the fringe of a district inhabited by large numbers of wood-workers, jewellers, and other craftsmen whose trades are connected with art. The works collected at Whitechapel were not all of them of very recent date (the vividly-coloured little embroidered triptych from the Clapton and Stamford-hill School of Art, for example, took a gold medal at National Competition two or three years ago), but they represented very fairly what is being done in at least four crafts—woodwork, jewellery, house-decoration, and embroidery. Was it chance or design which happily arranged that of the crafts most fully represented, two should be largely taught and practised within a short distance of the gallery while classes in the other two are rather to seek in the neighbourhood? Anyway by this means the dwellers in the East-end have the satisfaction of seeing that the metalwork turned at Aldgate by the Sir John Cass Institute is at least as good as any produced in other parts of London; and they can also feel pride in the excellent wood-work, ranging from simple carpentry to very complicated joinery from the Shoreditch Technical Institute and elsewhere—though they will have noted, if they are wise, that the best wood-carving comes from the West-end. It is rather a pity that the East-end woodworker should not be taught to do really well the sort of simple carving which lends itself to the decoration of furniture.

The large show of embroidery, coming from nearly all parts of London, emphasises the fact that embroidery classes are scarce in East London. Yet, surely there must be many a trade embroideress, say,

of military decorations (not to mention dressmakers), who would benefit as much by instruction in more all-round work as does, for instance, the trade jeweller. The embroidery covered a very wide field, and showed very plainly how much more methodically the craft is taught than it was a few years ago.

The little collection of work executed in the classes for house painters and decorators was also encouraging. The positive bad taste which characterised the productions of some years back seems to be steadily decreasing, and a very fair proportion of the exhibits at the East London Art Gallery showed, if no very great artistic feeling or promise, yet a certain taste and refinement which mark a decided advance. There was nothing very wonderful about the exhibition at Whitechapel, but it certainly did show, as local exhibitions of a similar nature have shown on a smaller scale, that the work being turned out in the technical classes under the London County Council is surely and steadily improving in quality.

A New Banner for Malvern Priory Church.—A really noteworthy banner has just been presented to the Priory Church at Great Malvern. It has been specially designed by Mr. J. N. Comper, after the old Prior's seal, and executed in the workroom of the Wantage Community, under the direction of Sister Dora. Modern church banners are not generally very interesting either in design or workmanship, but the one just dedicated at Malvern is a marked exception to the rule. Not only has nearly every detail of the restrained Gothic design been planned by the donor and the designer to contain some reference to the history of the Priory, but the embroidery is peculiarly fine. Instead of being of the ordinary shape, the banner, made to the dimensions of the famous Oriflamme of Conrad of Halberstadt, is practically a square with pendant tabs. The ground is formed of alternate strips of murrey and blue damask (the livery colours of the house of York), so equally balanced in weight that there is no unpleasant effect of stripiness. The main subject consists of a seated figure of the Madonna with the Holy Child, supported on either side by St. Michael (the patron saint of the Priory), and St. Martin of Tours (patron of another church held by the monks of Malvern) and, since kings of both houses were munificent donors to the foundation, the figures are encircled by an embroidered wreath of York and Lancaster roses. The brilliant greensward in the foreground dotted with flowers of varying hues, serves the double purpose of helping the colour scheme and of drawing the figures together, so that, in spite of the dividing tendency of the striped ground, they form a compact subject within their circular frame. In each of the pendant tabs is an heraldic shield bearing arms connected in some way with the history of the abbey: the arms of Edward the Confessor, who granted its first charter; the arms of France and England quarterly; the arms of the dioceses of Worcester and Gloucester, in which the possessions of the priory lay. These shields are well worth looking at for the vigour with which the martlets, lions, &c., are executed—very unlike the dull commonplace of so much modern heraldic work.

The four figures are carried out entirely in stitchery—the faces and part of the drapery in floss, the rest in *nué* gold work. They are, of course, Gothic figures, simple and severe, such as it is possible to execute satisfactorily in needlework; and not only are they worked with delicacy and feeling, but the drawing is very well preserved. The stern, ascetic face of the elderly St. Martin is remarkably well rendered, while the wings of the archangel (a peculiarly gentle St. Michael, by the way) in gold and blue and green floss, veined with the merest touch of silver passing, are a beautiful piece of colour and of workmanship. The stitchery is very fine, and not only bears but demands close inspection—but none the less the design tells well at a distance. The whole production, though too strictly mediæval in feeling to be really characteristic modern work, is worthy to go down to posterity as a twentieth century addition to the treasures of the Priory church at Great Malvern.

Recent Metal Work and Jewellery.—Metal work, and more especially jewellery and silversmiths' work, is the branch of artistic craftsmanship which for some years past has, perhaps, more than any other, been most universally pursued by the amateur and by the artist-craftsman. It is really rare now-a-days to come upon an exhibition which does not include a case or two devoted to silversmiths' work of some kind. Other crafts, such as leather work, bookbinding, and embroidery, are often represented, but metal work is always there; and, though there is still too much amateurish jewellery and badly-hammered copper work about, as well as a certain amount of streaky, rather unhappy-looking enamel, the cases scattered about the rooms of the London galleries at the present time contain, for the most part, workmanlike productions quite worth looking at—and at times real works of art.

The Exhibition of Fair Women at the New Gallery, besides affording an opportunity to show Mr. Charles Conder's paintings on silk and gauze, which have attracted so much attention of late, offered, by its very title, a home for the show of jewellery. As a matter of fact, there were only two cases of it—a small one containing tasteful necklaces and pendants by Mr. and Mrs. Gaskin, and a larger one devoted to the work of Mr. H. Wilson. The most interesting objects in this case from the point of view of workmanship were two large hair combs decorated with silver work and little plaques of *plique à jour* enamel. The position in which a comb is worn in a woman's hair naturally allows its ornamentation to be seen pretty frequently against the light, and so gives excellent scope for the display of transparent *plique à jour*; and the workmanship on Mr. Wilson's combs, which is of the delicate kind, met with in old

work, and not to be compared with the beautiful but less carefully finished modern Scandinavian enamelling, deserves to be shown to advantage.

The Lyceum Club generally has some jewellery amongst the objects on view in its Arts and Crafts room, and at the present time the show includes the handiwork of most of the best women jewellers. The work of Miss Kirkman is always interesting; whilst that of Mrs. Roscoe Mullins, who has been turning her attention with very happy results to buttons and sleeve links in silver without stones, is very well worth looking at. Another gallery which, amongst a large quantity of pictures found room for the display of some jewellery and silversmiths' work, was the Grafton. At the exhibition held there by the Ridley Art Club there was a small case of Miss Ramsay's jewellery, as satisfactory in design as it was excellent in workmanship, and a very much larger case devoted to jewellery and silver and copper work by Mr. Nelson Dawson. The exhibits in this case ranged from the lightest of light jewellery, all aglow with brilliant translucent enamel, to heavy copper and steel candlesticks ornamented with opaque *champlevé* enamel rather after the manner of some of the old English brass work at the Victoria and Albert Museum. The colour of the translucent enamel on the chains is quite beautiful, but the plaques of the same material used to decorate some of the vases are less satisfactory. One of the most pleasing of the larger pieces of work was a hot-water jug after a model not very far removed from an old-fashioned French *bouillotte*. Altogether Mr. Nelson Dawson had got together a little collection admirably fitted to show the compass of his work.

CORRESPONDENCE.

DEW-PONDS.

I have seen Mr. A. E. Carey's letter which appears in your issue of the 26th ult.

I an not aware that White, of Selborne, made any "luminous" notes on the subject of dew-ponds; the phenomenon of the water remaining in the pond without any visible supply was perplexing to him, but his notes can hardly be called "luminous."

The point, however, which interests me in Mr. Carey's letter is that he would not commend the method suggested by myself to those who are anxious to obtain a water supply by means of a dew-pond, and he thinks that he can suggest a better plan. Doubtless he is referring to the patent method, about which he spoke in a former letter to the *Journal*.

I may at once say that I have no axe to grind. My only desire is that the best condensing surface should be made known, and that its cost should not be a prohibitive one. Assuming that this is also Mr. Carey's desire, I beg to make the following proposition:—

That he and I, on some spot to be determined, should each construct a condensing surface, having the same area, the limit of cost of the respective methods to be within 10 per cent. of each other, and that neither surface is to be mechanically chilled, but that both are to work automatically.

The methods adopted, and the results obtained by condensation, are to be the measure of the merits of the respective surfaces, and the methods and results are to be published in the Royal Society of Arts *Journal*. Each party is to pay the costs of his own experiment, and to share such costs as may be common to both.

George Hubbard.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

Cuir Bouilli.—This method of treating leather is described as a lost art in all books on leather work which I have had an opportunity of consulting. Can any reader inform me where a description of the process can be found, or give information on the following points:—Is the leather (cowhide) used for embossing suitable for *cuir bouilli*? Is the leather boiled in water, or are any, and what, ingredients added? Is any part, more particularly the incising of the outline, of the work done before boiling? If not, what means are used to keep the leather soft after boiling for a time sufficient to allow the incising and modelling to be carried out.—E. H.

The River Orange.—I should like to know what English, French, or American geographical accounts there may be of the river Orange (South Africa)? Of English war literature and school books I have knowledge, but I can trace no thorough geographical paper.—Edwin A. Walford.

ANSWER.

Japanese Waltzing Mice.—I think it is the generally accepted theory that these mice originated from ancestors with diseased brains, and that continual inbreeding has established a fixed variety. The waltzing is, no doubt, due to a defective brain. Excessive inbreeding of the ordinary species of mice will bring about a similar result.—Mrdicus.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

APRIL 28.—"The Resources of the Peruvian Andes and Amazon." By C. REGINALD ENOCK, F.R.G.S. SIR CLEMENTS ROBERT MARKHAM, K.C.B., D.Sc., F.R.S., will preside.

MAY 5.—"English Furniture Design and Construction." By PERCY A. WELLS.

MAY 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S. The RIGHT HON. VISCOUNT MIDLETON, late Secretary of State for India, will preside.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

APRIL 20.—"South Africa." By the HON. CHARLES GIDEON MURRAY. LORD BRASSEY, G.C.B., D.C.L., LL.D., will preside.

MAY 18.—"Canada as a Field for British Investment." By J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

LECTURE I.—APRIL 26.—The principles of dynamic support—The action of an inclined plane—The law of pressure reaction as a function of velocity—The law of pressure as a function of angle—Frictionless flight—The law of power expenditure as based on the laws of the pressure reaction—The laws of pressure reaction and power expenditure quantitatively considered: a discrepancy—The dipping front edge and its lesson—Cyclic motion in its relation to the supporting reaction—Direct evidences of cyclic motion—The quantitative treatment on the hypothesis of a cyclic component—The power expenditure under real conditions—Skin friction, its nature and magnitude—Skin friction as affecting power expenditure—Skin friction and other factors as limiting the wing area—Aeroplane *versus* pterygoid form—Meaning and influence of *aspect*—Importance of aspect ratio—The gliding angle, as measure of resistance—The minimum gliding angle as a function of the velocity of flight—The coefficient of skin-friction and the aspect ratio as affecting the value of the minimum gliding angle—The angle of inclination as related to the minimum gliding angle—The pressure proper to least resistance—The theory of screw propeller efficiency—Comparison of theoretical results with measurements of birds, flying machines, &c.—Controversy as to influence of skin-friction—Conclusions as affecting the problem of mechanical flight.

LECTURE II.—MAY 3.—The principles of stability—The simple glider—The ballasted aeroplane—Form of the flight path as observed—The flight path as plotted from the equation—The phugoid chart and its teaching—Changes of amplitude of the phugoid curve and influences that lead to such changes—Conditions of flight path, stability and the equation of stability—Effects of propulsion on stability—Influence of the flexibility of the aerofoil—Lateral stability—Rotative stability—The stability of birds and of flying machines in practice—Flight path stability desirable but not essential to flight—Steering in altitude and azimuth—Gyroscopic couples—The boomerang—The gyroscope as an aid to stability.

LECTURE III.—MAY 10.—*The Flying Machine.*—The function and uses of the flying machine—Possible types—The conditions to be fulfilled as defining the type—The need for high velocity—The difficulties of high velocity—The horse-power problem—Motors for flying machines and the conditions governing their weight—Fuels available and the relative importance of fuel economy—Propulsion and the propeller—The use of gearing—The limitations of flight as due to the mode of propulsion—Other modes of propulsion—Wing flapping and its efficiency—Soaring—Starting and alighting—Questions of design and construction—Steering and steering mechanism—Flying at a height—The advantages and disadvantages of altitude—Types of flying machine in practice—The future of flight—The flying machine as a mode of locomotion, in peace and war.

Journal of the Royal Society of Arts.

No. 2,943. VOL. LVII.

FRIDAY, APRIL 16, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, APRIL 20th, 4.30 p.m. (Colonial Section.) HON. CHARLES GIDEON MURRAY, "The Road to South African Union."

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY'S EXAMINATIONS.

[In the year 1897 the International Congress of Technical Education held its meeting in London, at the Society of Arts' House. At this meeting a paper on the history of the Society's Examinations was read by the Secretary, Sir Henry Trueman Wood. The paper with certain additions was reprinted in the *Journal* in 1903, and it is now republished with such further alterations and additions as are required to bring it up to date.]

The Society's Examinations are conducted simultaneously at a number of different centres throughout the kingdom, through the agency of local examination committees established for the purpose by the Society. The papers in each subject are sent down in separate envelopes to the secretary of the committee immediately before the day of examination. The envelopes are opened in the presence of the candidates, and the papers distributed. The worked papers are sealed up at once and despatched to the office of the Society. They are then distributed among the various examiners who report upon them, and the results are published.

EARLY HISTORY.

The examination system of the Royal Society of Arts was an outcome of the Great Exhibition of 1851, which, as is well known, was originated by the Society. In November, 1851, Mr. Harry Chester, then a Vice-President of the Society and afterwards Chairman of the Council, submitted to the Council a scheme for the formation of a union of mechanics' institutions, the principal object of which was to encourage the founding of such institutions, and to develop the educational facilities which they provided.

Among the early suggestions for the utilisation and development of these institutions was a proposal for a general system of examinations among their members. In December, 1853, Mr. Chester definitely proposed the establishment of such a system, and in the spring of 1854 a scheme of examinations was published. The scheme was of a very comprehensive character, and included the following subjects:—1. Mathematical Sciences; 2. Experimental Sciences; 3. Sciences of Observation; 4. Mechanical Sciences; 5. Social Sciences; 6. Fine Arts; 7. Moral and Metaphysical Sciences; 8. Literature. This very elaborate programme proved a little impracticable, and it is not to be wondered at that only a single candidate offered himself for examination in March, 1854. The promoters of the movement were not, however, discouraged; the scheme was remodelled, principally by Dr. Booth, at that time an active member of the Society, and in 1856 an examination of 62 candidates was held at the Society's house. The subjects of this first examination were:—1. Book-keeping; 2. Arithmetic; 3. Algebra; 4. Mensuration; 5. Geometry; 6. Mechanics; 7. Chemistry; 8. Animal Physiology; 9. Botany; 10. Agriculture; 11. Geography; 12. Physical Geography; 13. English History; 14. English Literature; 15. Latin and Roman History; 16. French; 17. German; 18. Freehand Drawing.

In the following year, 1857, the first attempt at provincial examinations was made, and an examination was held at Huddersfield, as well as in London, the examiners of the Society going down for the purpose. The desire of

increasing the number of examination centres and the obvious impossibility of sending examiners simultaneously all over the country, led in 1858 to the elaboration of the system of local committees to supervise examinations worked from a single centre.

The College of Preceptors.

The Society of Arts, however, cannot claim the sole credit of the invention of the system of local examinations. In 1850 the College of Preceptors (established in 1846) was considering the best means of examining the schools of its members. It commenced by sending down examiners, its first school examination having been held in December, 1850, at Nottingham, but in 1853 the experiment was tried of collecting pupils to a centre and examining them by means of papers sent down from London. The experiment proving successful, the system was regularly organised in the following year, 1854, and has been continued ever since.

It will be seen that the College of Preceptors' Examinations preceded those of the Society of Arts by two years, but the objects, the conditions, and the methods of the two systems have been so different that there has never been any but the most friendly rivalry between them. In 1856 a conference was held at the Society's house between representatives of the two bodies, the College being rather afraid that the Society's Examinations would interfere with their own. It was soon apparent that the two systems were intended to occupy different ground, and were not likely to affect one another. In practice this has proved to be the result, and it has never been found that they have interfered in the least with one another.

To the Society's Examinations in 1858, 58 institutions sent up 288 candidates; in the following year there were 480; in 1860, 586. The numbers increased steadily till 1865, when there were 1,899; the next year showed a slight diminution, and then there was a further increase, till the number of 2,160 was reached in 1869. This was largest number examined under the original system.

University and Government Examinations.

The University Local Examinations were established in 1858. The establishment of Elementary Drawing Examinations by the Department of Science and Art was about contemporaneous with that of the Society's Examinations. The Science Examinations began later, in 1861, and as these developed, it was found that the Society's Examinations were in many respects competing with those of the Department. The same candidates were being examined in the same subjects, and there was an evident waste of power. In 1870 this led to the abandonment of 17 out of the 36 subjects then included.

Changes in System, 1876.

In 1871, when the Council was considering the establishment of a system of Technological Examinations, of which an account is given below, they passed a resolution to discontinue the General Examinations, but on the application of some of the more important of the Institutions in Union, they rescinded the resolution and determined to continue the examinations for a further period. This was done, on the same system as before, till 1876, when the programme was revised, and the plan on which certificates were granted was somewhat modified. Previously, certificates had been granted for single subjects, but in that year a "Commercial Certificate" was established in addition, to take which it was necessary to pass in, at least, three subjects. Very few of these certificates were ever taken, the system of single certificates for single subjects being more popular and better suited to the needs of the class of students who take up the Society's Examinations.

Proposed Abandonment, 1879.

In 1879, the question of abandoning the Examinations again arose, it being thought that the ground was covered by other agencies. To quote from the report of the Examination Committee in 1879:—

"The Committee feel that the time has now come when the Society should cease to compete with other educational agencies more influential in the work of examination. With the Education Department examining millions of children in elementary schools, and thousands of young persons in night classes; with the Universities holding their local examinations throughout the country, for young persons of a higher class; with the Science and Art Department examining students in every branch of science and art; with the new City Institute developing yet further the Technological Examinations just handed over to them by the Society; with other agencies, such as the College of Preceptors, doing kindred work, the Society of Arts may well retire from the field, having in all these various directions acted as pioneer. It held science examinations before the Science Depart-

ment, examinations in literature before the Universities went afield to meet the classes who could not go to Oxford or to Cambridge. It has seen the system it established develop, with the aid of Government funds, as it could never have grown without such help, and the time has now arrived when it may cease to compete with the agencies it has done so much to foster."

The System Re-modelled, 1882.

In pursuance of the course mentioned in this report, no examination was held in 1881, but again, some of the institutions where the examinations were held protested, and on further consideration it was determined to continue the Examinations, but to try whether they could not be made self-supporting. Hitherto they had been free. In 1882 a fee of 2s. 6d. was charged to each candidate, and this charge has since been continued. The "Commercial Certificate" was abandoned and the old system was resumed of giving a separate certificate for each subject. The natural result of fees being charged was a considerable falling off in the numbers examined. In 1882 only 695 papers were worked as compared with 2,325 in 1880. The numbers, however, soon began to increase again. In 1890 there were 2,474; in 1895, 5,108; and in 1900, 9,808. This very considerable increase was doubtless, to a very great extent, due to the facts that the London County Council had, by the Technical Instruction Act, 1889, been placed in possession of large funds available for the promotion of technical education; and that certain commercial subjects were scheduled by the Science and Art Department as subjects coming within the scope of the Act. The commercial subjects so scheduled were precisely those in which the Society of Arts examined.

Elementary Examinations.

In addition to its Commercial Knowledge Examinations, the Society conducted, from 1856 to 1894, Elementary Examinations. These were really carried on by District Unions and Local Boards in connection with the Society. All the Society did was to supply identical examination papers, the results being examined and certificates awarded by examiners appointed by the Local Boards. The Society supplied the certificates, but accepted no responsibility as to their award. The system, though useful at its first establishment, was never found to work in a very satisfactory manner, and in 1895 it was abandoned.

There was, however, always a demand for examinations of a more elementary character than the general examinations, and in consequence elementary examinations in modern languages (French, German, and Spanish) were established in 1897. These were fully appreciated, and eventually, in 1901, an Elementary or Preliminary Grade was added. The subjects selected for this Grade included Handwriting and Correspondence, Shorthand, Book-keeping, Arithmetic, Typewriting, Commercial Geography, French, German, and Spanish. In the first year in which the Elementary Examinations were held (1901), there were 4,458 papers worked in the different subjects, of which 2494 passed and 1,964 failed. The percentage of successes and of failures was, therefore, 56 and 44. There has since been a continuous growth, till last year (1908) the numbers reached 9,811 with a percentage of 64·35 successes and 35·55 failures. It may, therefore, fairly be concluded that the increased numbers have been accompanied by a slight improvement in quality.*

Present System Started in 1905.

In 1905 some considerable modifications were made in the Programme. In the system existing in 1904 there were two grades—Senior and Junior. In the Senior there were three classes, and in the Junior, or Elementary, one. For some years past suggestions had been made from various quarters to the Council that it would be desirable to establish a higher grade of examination, which might be taken by more advanced students than those entering for the examinations as they then were. After very careful consideration, and a good deal of correspondence with the local committees, it was determined that the examinations should be arranged under three stages. Stage I. was to be Elementary; Stage II., Intermediate; and Stage III., Advanced. The Elementary was to be as before, a pass examination, and in each of the two upper Stages there were to be two classes. It was proposed that the Advanced Stage (No. III.) should practically correspond with the First-class of the old Grade II. and the upper part of the Second-class, while the idea was put forward that the standard should be very gradually advanced. The Intermediate Stage was made up of the Third-class and the lower part of the old Second-class of Grade II.

* During the preceding ten years, no changes of importance were made. Domestic Economy, which had been in the Programme almost from the beginning, was dropped in 1901.

This system has since been carried on without any alteration, and it has been found to work very well. The advance in the standard has been very trifling, as it was found from the general character of the papers sent in that any considerable elevation of the standard would involve an undue amount of rejections, that is to say, more than a third of the candidates entering. Some new subjects were also added to the Advanced Stage, the principal of which were Commercial Law and Accounting and Banking. A slight change was also made in the fees, those for the Advanced and Intermediate being left as before at 2s. 6d., and for the Elementary Stage the fee was fixed at 2s., with a reduction of 1s. for every subject after the first subject taken up.

The new system resulted in a very large increase of candidates, from 17,771 in 1904, to 21,253 in 1905. This total gradually grew to 22,597 in 1908. In the present year there will be a still further increase, but the precise number is not yet known.

In 1907, at the request of the Army Council, it was arranged that a special annual examination in Shorthand should be held for soldiers at any centre fixed by the Army Council throughout the Empire. Last year (1908) a similar examination was arranged in Typewriting.

Value of the Certificate.

As regards the practical value of the three sets of certificates, it may safely be said that a certificate of the Advanced Grade (especially of the First-class) may be taken to afford an employer a reasonable assurance of a competent knowledge of the subject (so far as it can be tested by examination) on the part of a candidate for employment who presents it. A certificate of the Intermediate Grade may be taken as evidence that the person presenting it has made a study of the subject and has made some progress in that study. An Elementary certificate in the hands of a young person shows that special study of the subject has been attempted, and its successful pursuit looked forward to in the future. It must be remembered that this grade is only intended for young persons of, or just over, school age.

Viva Voce Examinations in Modern Languages.

A question which had been for a long time before the Council was the holding of *vivâ voce* examinations in Modern Languages, and as far back as 1870 suggestions, made by the late Mr. Hyde Clarke, for holding such examinations locally, were included in the programme. Nothing, however, came of these suggestions. It is quite obvious that no paper examination can be an adequate test of knowledge of a spoken language; but the difficulties connected with the holding of colloquial examinations simultaneously at a number of different centres for a long time proved insuperable. In 1902 the idea of holding such examinations at the same time as the other examinations was abandoned, and it was announced that examinations in French, German, and Spanish would be held at any date at any of the Society's examination centres where proper arrangements could be made. Portuguese and Italian have since been added to the list of subjects. The experiment proved very successful. In the first year 280 candidates were examined. The numbers rose to 681 in 1905. Since then there has been a slight falling off. Last year (1908) there were 615. The percentages of success and failure in 1902 were 72·2 and 27·8. In 1908 they were 76 and 24. This points to improvement in the preparation of the candidates. It is found on the whole that nearly all the candidates who entered have a very fair colloquial knowledge of the language, while certificates of distinction have been granted to a great many who have shown thorough proficiency. No difficulty has been experienced in conducting the examinations satisfactorily, thanks to the energy and ability of the gentlemen whose services as examiners the Society have been successful in securing.

Technological Examinations.

The Technological Examinations, referred to above, were instituted in 1873, at the suggestion of the late Sir John Donnelly. These examinations were intended to test the knowledge possessed by artisans of the subject-matter of their respective industries. It was arranged that they should be held in connection with the May examinations of the Science and Art Department, the technological papers being given out with those of the Department. Before a candidate could obtain a certificate, he was required to pass a Department examination in certain specified science subjects, these varying according to the technological subject taken up. Certificates of three grades were given, elementary, advanced, and honours, corresponding with those of the Department examination. No attempt was made to test practical skill, but

each candidate was required to produce a certificate from his employer in which his competence was stated. The number of candidates was never great. In the first year (1873) only six entered and the numbers gradually increased to 68 in 1870, and 184 in 1878.*

In 1879, on the foundation of the City and Guilds of London Institute, the Technological Examinations were handed over to that body. From the funds placed at its disposal by the City companies the Institute was able to offer to teachers payments on the results of the examination like the grants of the Science and Art Department. Teachers were thus enabled to form classes and to send pupils in for the examination, and a large increase in the number of candidates took place. These examinations now form an important part of the Institute's work, and attract annually a very large number of candidates. In 1908 the number examined was 22,458. Large additions have also been made to the list of subjects, which now number 75. No great change has been made in the general character or system, which remains much the same as that proposed by Sir John Donnelly, but the details have been considerably modified, and in some cases a practical examination, to test handicraft skill, has been provided.

Examinations in Practical Commercial Knowledge.

In 1889 an attempt was made to establish a system of examinations in "Practical Commercial Knowledge." Syllabuses for two subjects, "The Commerce of Food" and "The Commerce of Clothing," were issued, but no candidates came forward, and after a second year's trial, the proposition was dropped.

Practical Examinations in Music.

In 1879, at the suggestion of Dr. Hullah, examinations in Practical Music were established, that is to say, examinations at which the actual capacity of students to play an instrument, or to sing, could be tested. It was intended that these examinations should apply to a less advanced class of candidate than those who entered for the well-known examinations of the Royal Academy of Music, at the time when the Society's system was started, or who now enter for those of the Associated Board of the Royal Academy and the Royal College of Music. It is believed that the Society's examinations have fulfilled their purpose, and have proved a useful means of encouragement to many musical students. Dr. Hullah acted as examiner from 1879 till his death in 1884, and was succeeded by Mr. W. A. Barrett, who died in 1891. The work was continued by Sir John Stainer, Sir Joseph Barnby, and Mr. W. G. McNaught. In 1895 Mr. John Farmer was appointed, and he continued to act till 1899, when he was obliged to give up the work in consequence of illness, which, at a later date, terminated fatally. The examinations are now conducted by Dr. Ernest Walker and Mr. Burnham W. Horner, who served as Assistant Examiners to Mr. Farmer. The numbers examined have never varied within very wide limits. In the first year there were 117 candidates. The numbers increased gradually to 276 in 1891, and to 393 in 1895. The largest number yet examined was 566 in 1900. During the last few years there has been a small but steady diminution. The standard has not varied greatly, but is now a little higher than it was. The general level of attainment is reported by the examiners to be slightly higher of recent years.

Conclusion.

It will be seen that the development of the examinations of the Society during the half century covered by this account has been very remarkable. The 62 candidates who took part in the experimental examination of 1854, had increased to 2,325 in 1880. The abandonment of the examinations in 1881 caused a great falling off when they were renewed in 1882, but, giving round figures only, the 700 candidates of that year steadily increased to 9,800 in 1900. The Technical Instruction Act of 1899 caused the numbers to shoot up in 1901 to over 13,000, and the changes introduced in 1905 brought the increase in that year up to over 21,000. There has been a slight, but steady, growth in the last three years, the numbers last year (1908) being 22,597, and those for the present year (1909) will show a still larger proportionate increase, though the precise figures cannot as yet be given. The number of centres at which the examinations are now held, is 415. Since 1882, when the

* The following were the subjects included in the 1878 examinations:—Cotton manufacture, Paper, Silk, Steel, Carriage-building, Manufacture of Pottery and Porcelain, Gas manufacture, Glass, Cloth, Silk-dyeing, Wool dyeing, Calico-bleaching, dyeing, and printing, Alkali manufacture, Blow-pipe analysis.

present system started, down to and including 1908, 238,605 papers have been worked.

As to the subject-matter of the examinations, the scheme which originally may be said to have covered pretty well the whole range of general education, except the dead languages, was gradually re-modelled and reduced until it now comprises commercial education alone, with the sole exception of music.

Full details of the present system, with syllabuses and past examination papers in the different subjects, will be found in the Society's annual Examination Programme, while the actual results are given in the lists published by the Society as soon as possible after the holding of each examination.*

THE INTELLIGENCE OF THE ELEPHANT.

The distinction between the reasoning capacity of man, and the instinct or intelligence of animals, is a theme on which much has been written, and which, even now, is in great dispute. Similarly, there is considerable difference of opinion as to which of a group of animals, comprising the horse, cat, elephant, various members of the monkey tribe, parrots, canaries, and even fleas, may be said to stand first in this respect. By general consent, the dog would appear to hold the first place in the arrangement of animals according to their intelligence. But several authorities hold different opinions. Dr. W. L. Lindsay, who has made a highly elaborate study of the "mind in the lower animals," arranges the various mammalia in the following order:—

1. *Bimana*, higher man only.
2. *Quadrumana*, especially the larger anthropoid apes.
3. *Carnivora*, including especially the dog and cat.
4. *Proboscidia*, the elephant.
5. *Ungulata*, especially the horse, mule, and ass.
6. *Rodentia*, especially the beaver and rat.

As a rule the elephant is ranked about third or fourth, by the majority of writers. Cuvier places the elephant in point of sagacity after the dog and some other species of carnivora. Sir Emerson Tennent is much of the same opinion, and Mr. G. P. Sanderson, who has been so long and intimately associated with elephant catching in India, places them in respect of reasoning faculties far below the dog and some other animals, adding that the former are "decidedly wanting in originality."

On the other hand, Mr. W. T. Hornaday, who has had practical experience of elephants and who has brought much scientific analysis of the evidence to bear on the subject, considers there is no question of the elephant's *general* intellectual superiority over all other animals except higher man. He would sub-divide the intelligence of an animal into classes, viz.—1. Powers of independent reasoning or observation. 2. Memory. 3. Comprehension under tuition. And 4. Accuracy in the execution of man's orders. Closely allied to these are the moral qualities, such as—(1) Amiability, which guarantees security to his human associates; (2) patience or submission to discipline or training; (3) courage, which gives self-confidence and steadiness; and (4) a disposition to obedience, with cheerfulness.

In considering instances which may come under one or other of these categories, it is undoubtedly fairer not to argue from any particularly intelligent specimen or example of a given race or species, but to consider them as a race or species. This is an argument in favour of extending the basis and range of observation as widely as possible.

One important consideration telling in favour of the elephant, as contrasted with the dog, is that the latter enjoys, as a rule, unrestrained liberty, roaming about through his master's house and premises, both in town and country, and mingling freely with all kinds of men and domestic animals, while the elephant in captivity is chained to a stake, with no liberty of action whatever. And when released from his chain, he is under the complete control of his *mahout*, who directs his every act. There is no telling what wonderful powers of reasoning captive elephants might develop if they could only enjoy the freedom accorded to most dogs.

As for wild elephants, Mr. Hornaday has frequently seen them—(1) reconnoitre dangerous ground, by sending forward a scout or spy; (2) communicate intelligence to each other, by signs; (3) retreat in orderly silence from a lurking danger; and (4) invariably march in single file, like the jungle tribes of men.

Where wild elephants have to be captured by tame ones, the human-like intelligence displayed by the latter in first entrapping and then tying the captives, one by one, in a "Kheddah" is extraordinary. They enter into the business with both spirit and understanding of all the different stages, and as occasion requires will deceitfully cajole or rigorously punish a troublesome captive. In connection with this a curious incident is on record of a female elephant which was purchased at a sale of her late master's effects, without the new owner having the least notion that she was (by profession) a "koomkie" or decoy. The mahout, glad enough to be out of an employment that was fraught with danger, said nothing to his master about the true character of the animal. One morning "Lutch-mee," which was her name, was not to be found, and several days having elapsed without news she was given up for lost. About a week after, Lutch-mee made her appearance as if nothing had happened.

* The Programme for the year, and such Programmes of previous years as are not out of print, can be obtained at the Society's office, price 4½d. each. The results for each year can be obtained at the same place, price, for each Stage, 6d.

and her master mounted her to have a ride. He happened to proceed towards a grassy jungle, which the animal several times tried to enter, but was turned aside each side by the mahout, who was afraid her holiday might have developed in her some wild and dangerous habit or taste. At last Lutchmee grew quite uncontrollable and rushed into the jungle, only stopping at a thick clump of trees, where, to the intense surprise of her master, a large male elephant was discovered, round whose legs, secured in the most approved fashion to four trees, was the iron chain with which Lutch-mee was usually fastened to her own picket at night time. She was resolved to resume her old profession, and had consequently set about carrying on the business on her own account, thus securing one of the finest elephants that had been taken for many years.

With some writers, however, it is still a moot point whether the predominating quality of the elephant is not extreme docility coupled with caution rather than very abnormal sagacity. This is the opinion of several Eastern authorities. One ot these, who had had considerable opportunity of studying the characteristics of elephants, comments in a letter to the writer on the wonderful work these animals do in dragging and sorting timber and in breaking up obstructions caused by logs and miscellaneous flotsam in streams; but in all this he inclines to think it is the strength and obedience to the mahout's orders rather than the innate cleverness of the beast that call for admiration.

In Burma and other parts the timber is got out and floated on the smaller streams and creeks, which are full during the monsoon. The logs are carried down the creeks till they are arrested by a boom at the junction of a main creek, and a navigable, or rather "raftable," river. In the centre of the boom there is a practicable entrance or opening, and through this aperture the elephants are trained to shoot the logs, one at a time, a task at which they get particularly clever, coiling their trunks round the logs, letting them swing in the current till they are "end on," and then propelling them through the opening. The narrator of this incident has seen them break up a jam of thousands of logs, which had got massed together above a bridge, and shoot them all through the openings in the neatest way. For a time the best trained elephant will even work alone on the water, obeying the directions of the mahout, standing on the bank; but, as a rule, a man must sit on the elephant's head, a very wet job, as when an elephant swims only just the top of his head is out of the water.

Certainly in ancient times their intelligence had not struck the great conquerors of Macedonia, Epirus, Greece or Rome as anything very exceptional, for it was their strength and height that chiefly led to their employment in warfare, and also the terror and demoralising effect produced on an enemy unused to such strange monsters. Alexander the Great appears to have been the first European to have used elephants in war, and his successors had even more frequent recourse to them. The Lagidæ and also the Seleucidæ made considerable use of them in their campaigns, and Antipater brought over into Greece the first elephants ever seen in that country. Pyrrhus conveyed some to Italy and employed them in his contests with the Romans, who were thus to some extent familiarised with these creatures even before encountering them in their long struggle against the Carthaginians. The usage of the latter was followed by the kings of Numidia, and Jugurtha had also recourse to elephants, but unsuccessfully, in his endeavours to overcome the legions of Metellus. Also Juba fared no better in pitting them against Cæsar's army. Finally, the Romans themselves adopted them for military purposes, but they never seem to have placed much reliance on their help, on account no doubt of their liability to panic, and definitely abandoned them towards the end of the republic, retaining them solely for displays and contests in the circus and amphitheatre. One of the chief decorations of the great Flavian amphitheatre or Colosseum at Rome was a barrier, or *chevaux-de-frise*, formed of elephants' tusks, about eight feet in length, interlaced in a fence or fret-work of gilt iron. This acted as a barrier against the possible attacks of wild beasts or attempts on their part to leap out of the arena.

During the long and sanguinary struggle between Persia and the empire, elephants made a temporary re-appearance in the armies of the Sassanian kings, particularly in the sieges in Mesopotamia and Colchis. From the fall of the Sassanian dynasty the elephant disappeared as an auxiliary in warfare, except in India, where it continued to play a more or less prominent part in fighting till the universal adoption of fire-arms finally banished it from the battle field. Altogether one can trace the military employment of this beast with approximate continuity through some twenty centuries.

It is interesting to note that during these times the elephant appears to have been far more widely spread than nowadays. Armandi, whose work is a standard authority on the subject, collects a body of evidence tending to prove that the animals were found in plenty in Numidia and Mauritania as far as, if not beyond, the Atlas Mountains. In fact, after the submission of Carthage and conquest of Northern Africa, the Romans symbolised those subjugated provinces by the picture of an elephant or a woman crowned with a head-gear distinguished by a trunk and two tusks. In a similar way Egypt was pictured by a crocodile and Judæa by a palm tree. In our time, India has been symbolised by a Bengal tiger, Australia by a kangaroo, Canada by a beaver and so on.

In the well known Sanskrit epic, the Mahábhárata, as well as in other Sanskrit works, the prominent use then made of elephants for military purposes was indicated by the following figures, which are laid down as those of a model army, viz.: 109,350 in-

fantry soldiers, 65,610 horsemen, 21,870 war chariots, and 21,870 elephants.

In modern times, our occupation of India seems to have inaugurated a great change in the utilisation of the elephant for man's purposes. The invention of firearms had already led to their practical abandonment for battle, except as purely beasts of burden, and it is in training them to act as such, and in developing what is probably the maximum of reasoning power observable in the brute creation, that such remarkable results have been obtained in India.

In accompanying batteries of artillery they have been found very useful, the bullock teams having often proved powerless to extricate a gun from a mud-hole or morass. Captain Walter Campbell tells us that when a gun comes to grief, the elephant marches up with the important air of an experienced engineer, and deliberately inspects the state of affairs. Twisting his trunk round the spoke of one wheel, he gives it a lift, as if to ascertain the depth and tenacity of the mud, and then quietly walks round and does the same by the other wheel, dropping it again with a knowing twinkle of the eye, as if he said to himself, "All right, I can start her, I think." Then he deliberates for a few minutes, gives a slight push here and a slight push there, when, having at last made up his mind as to the best mode of proceeding, he probably applies his forehead (previously padded) to the muzzle of the gun, and, uttering a shrill trumpet-like sound, as a signal for the gun bullocks to pull together, pushes against it with all his weight, while the bullocks obey the signal and pull away too. This generally starts the gun. But if the bullocks are sulky and refuse to obey the signal, the elephant gets perfectly furious, and rushes at them, brandishing his trunk with such ferocity as usually to compel obedience.

Elephants require the greatest care in respect of diet and general attention, as, though they are so strong, they are delicate, and the neglect of certain well understood precautions very soon impairs their health. Habitual work and sound and timely rest—about four or five hours—are necessary for them. When in health they are always in motion, either swinging the trunk, flapping the ears, or moving about. If they stand quite still it is a clear sign they are out of condition or unwell.

They are mainly used for dragging timber in Burma, but some authorities consider they are unsuited for this, as the pressure from the breast bands lies upon the upper part of the chest, which forms the most delicate part of the animal's physique. Pushing timber down stream is, perhaps, the easiest work for which they can be used, and for this they are well adapted, but even then great care has to be taken of their feet, the soles of which are apt to get tender.

Mr. M. J. Slym, of the Burmese Forest Department, was once crossing a small river, in which the water rose to a little above the belly of the elephant. Slipping accidentally from the side to the middle of the stream, the animal suddenly became fixed and unable to move. Men were sent to the rescue, but they could ascertain nothing else but that his feet were surrounded by blue clay, and absolutely immovable. At last, everything having proved fruitless, Mr. Slym caused the stream to be dammed, and the water below to be baled out with native pots, after which the clay, on which the animal appeared to be standing, was removed, when it was found that he was standing upon a solid rock, on which his great feet acted like suckers. With great difficulty, some air was introduced below the soles of his feet, when he soon emerged from his predicament, after a detention of thirty-six hours.

As a rule, so Mr. Nisbet informs me, elephants are very cautious in approaching the banks of streams, and will carefully test the solidity of an earthwork before entrusting their whole weight on it. Similarly, they always try the strength of a wooden bridge, before venturing along it. Mr. Nisbet has only once known a loaded elephant fall, and that was a bad-tempered animal that was trying to throw down its load on a hillside, along which a narrow track led. The load, however, happened to be well tied on, and the result was that it overbalanced, and carried the elephant down the hillside. Elephants swim well, and have often been seen to cross the Irrawaddy in flood, and so ancient an authority as Ælian says they have been seen, at such times, carrying their young on their tusks.

When free, in its native woods, the elephant evinces rather simplicity than sagacity, and the rich profusion in which Nature has supplied its food, ought, one would think, to render it quite independent of all artifice. Indeed, Sir Emerson Tennent goes so far as to say that its intelligence seldom exhibits itself in cunning, but this is certainly incorrect as regards the "rogue" elephants, which, Sir Samuel Baker says, are extremely cunning, and respecting which he relates several characteristic stories. One incident, told to Sir Emerson, seems to disprove his own contention. A recently captured elephant was being led from the corral by two tame ones, when it suddenly began to falter, and at last sank to the ground, and lay there lifeless. The fastenings were removed from its legs, but all attempts to rouse it, or restore animation, failed, so it was decided to abandon the carcase. While the ropes were being removed the narrator and his friend leaned against the body. But the party had no sooner moved off a few yards than the elephant rose with the utmost alacrity and rushed off to the jungle screaming with joy.

Another incident narrated to Sir Emerson Tennent told how two Englishmen endeavoured to stalk a big rogue elephant that was devastating a cocoa nut estate. The brute suddenly rushed out of the jungle at the hunters, who fortunately were enabled in the nick of time to climb a tree. The elephant went straight for the tree. He first stood on his hind legs and made for the hunters with his trunk, but in vain, after which he coiled his trunk round the stem and

pulled at it with all his might, but also without effect. He then applied his head to the tree and tried to butt or push it down, after which he trotted round it several times trying to trample and break down the projecting roots. Failing in all these efforts and seeing close by a pile of timber which had been felled a short time before, he removed these logs carefully, one at a time, to the foot of the tree, tlll he had piled the whole lot, thirty-six logs, after which he deliberately clambered on to the top of them and once more raising himself on his hind legs tried to extend his trunk towards the hunters. This, however, was his last chance, for in doing this he presented a fair mark to their rifles and two shots finished him.

Colonel F. T. Pollok says he has often watched the elephants in a timber yard and the human way in which they will test the weight of a log requires to be seen to be credited. The tusker will lift up one end with his trunk, and, if he deems it within his power to lift the whole, he will shift his trunk gradually until he gets to the exact centre, then by kneeling down he will roll the log on to his tusks and will carry it either to be stacked or to the saw mill.

In tea estates the elephants are occasionally employed to help in building construction by keeping the masons supplied with blocks of stone, and if the wall be not too high they will not only take the block up but lay it quite correctly in its proper place. A Ceylon elephant used regularly to lay stones in this way under the orders of an overseer, to whom he used to signal to inspect and "pass" the work done, and to give permission for fresh courses to be laid. On one occasion the elephant placed himself against part of the wall, thus preventing the overseer from examining that part of the job. The latter, however, insisted on the animal moving aside, and the elephant, seeing his ruse had failed, at once began to pull down the wall which he had just built, and which he was quite aware was badly done, at the very spot where he had tried to conceal it from the eye of his master.

Mr. W. A. Fraser tells some quaint tales which show that the animal has a glimmering idea of what British sport means. Near Meerut an elephant race was got up in which four full-grown beasts were encouraged to negotiate a one mile course which they covered in five minutes. The pace was undeniably slow, compared with what one would see at the 'Varsity sports, but the ponderous beasts did their level best and they all finished close together. In a tug-of-war, elephan *versus* men, one of the former pitted his strength against 35 sailors, but the tars won the day.

The saw mills of Rangoon and Moulmein give daily the best elephant show to be witnessed anywhere. But one day a frightened native came down to the town office of the mill owner, with a typical Baboo's letter reporting "the caprices of a mad, demented elephant, who had already suicided 33 of his defunct relatives, and was now murderously intent on all having a similitude to his kind in the appearance of domestic milch buffaloes, and therefore," the Baboo added, "he is an exuberant bad fellow," pathetically concluding, "My household gods are dislocated because of his illogical discipline." All this sounded sad, and proved to mean that Raja Singh, as the brute was named, had not only picked the manager's dog-cart to pieces, as a boy would dissect a watch, but had demolished a score or so of the coolies' bamboo huts, including even the Baboo's, whose dignity had been thereby hurt. Fortunately the owner had a fighting elephant, who, though a good worker himself, liked nothing better than the occasional relaxation of thrashing a refractory colleague with an iron chain. An assistant executioner's services were secured from an adjoining yard, and the two swooped down upon Raja Singh to administer a little wholesome correction. At first he was highly elate, making sure he had enlisted two recruits to aid him in his fun. But when the heavy chains were brought to play upon his ribs and about his ears he began to think a bit. Then the Phoongye (priest) as the thrasher was called, and his mate varied the dose of punishment by battering Raja Singh backwards and forwards between them till he could scarcely stand, and was easily chained to a stout tree to reflect on the evils of losing his temper.

A few days though sufficed to restore him to his normal senses. When next seen he was pulling great slabs of teak from the tail end of the saw and carrying them off to a distance. A mahout, or driver, was perched on his back, but he had fallen asleep, and the Raja was doing all the work, and the thinking too. He would draw six or eight huge slabs from the pile with his trunk, place them very evenly together, put a chain round them, run it through the slip-hook quite correctly, and attach himself by his traces to the load. Then he would move off majestically, till he came to the pile of slabs, upon which he carefully placed all he had brought, each one in its place where it fitted best, all smooth and even, as a careful workman should.

As the mahout seemed to him to be doing rather less than his share of the job, Raja Singh began to fill his trunk with a few odds and ends on the return journey. A stray nail, three or four pebbles, a tuft of grass with a little earth clinging to the roots, and a discarded cheroot were among the treasures he found, and these, with an upward sinuous movement of his trunk, he suddenly blew against the mahout's naked stomach—one of the little jokes with which he loved to alleviate the hours of labour, just as any other navvy might. After that, who can say that animals are lacking in humour?

A little further off, the Phoongye was piling square timber. Huge beams, a foot square and more, and over 20 feet long, he was carrying on his tusks with ease, and in piling them he was as ingenious as the Raja. He would place one end on the pile, back to the other end of the log, lift it into position, and then take a "squint" along the pile to see that it was all straight. If either end stuck out

too far, he would place his trunk or forehead against it, and shove it in.

At twelve o'clock the whistle blew, and, with the same spirit of punctuality that induces the hod-carrier when half way up the ladder to drop his load of bricks at the striking of the clock, these monsters dropped everything, and turned to the mash-tub full of grain.

It is interesting to observe, however, that instances of sagacity are not confined to the more domesticated animals. A Burmese steam-ship captain, while anchored off the coast, used to see a female elephant and her youngster come down out of the jungle every morning and bathe in the sea. The little chap used to keep in shallow water, while the mother ventured further out; but one morning, while his parent was not looking, the youngster got beyond his depth, became frightened, and made a great to do. The mother pulled him ashore and gave him a good spanking with her trunk. Each succeeding morning the little one was compelled to stand on the bank while the mother first bathed herself, and afterwards washed him down with water fetched in her trunk.

A British officer riding on horseback through a forest, near Kandy, heard some big beast grunting repeatedly in a dissatisfied manner just ahead of him, and at the same time his horse began to show signs of alarm. A little further on he came in sight of a tame elephant carrying a huge beam on its tusks, and in sad trouble owing to the narrowness of the path which compelled him to hold the log in a slanting position, to avoid its catching in the trees on either side. On seeing the officer, the elephant promptly recognised the fact that there was not room for both to pass each other abreast, so the elephant backed sideways into the jungle, leaving space enough for the others to ride on. The horse was, however, too terrified to advance, whereupon the elephant retreated still further into the jungle, but without effect so far as the horse was concerned. On moving for the third time away from the path, the elephant began to show signs of impatience, whereupon the officer dismounted, and leaving the horse free, walked on by himself, and was eventually joined by his steed. The elephant then resumed his march through the wood, and his complaining grunts could be heard for some time after dying away in the distance. Although a simple occurrence, the infusion of something approaching a sense of courtesy invests this incident with a unique interest which, to a lover of animals, is quite touching. C. E. D. B.

DR. SWINEY AND THE SWINEY PRIZE.

Some notes which appeared in the *Journal* of June 23rd, 1899, contained most of the little that is known of Dr. George Swiney. He was educated at the University of Edinburgh, whence he graduated M.D. in 1816 with a thesis *De insania*, and he died at No. 9, Arlington-street, Camden-town, or Grove-street, as it was then called, on January 21st, 1844, in the 50th year of his age. He appears to have been a man of very eccentric habits, living in almost complete seclusion and only leaving his house four or five times a year. His funeral was so peculiar that it was long remembered by the inhabitants of the neighbourhood. In accordance with the instructions of the dead man, the coffin was covered with yellow cloth studded with white nails, and thrown over this was a yellow velvet pall edged with white silk. Immediately behind the coffin came three young girls, dressed in white and wearing violet cloaks, and straw bonnets, trimmed with white satin ribbons. The mourners presented a most singular appearance, resembling more a wedding than a funeral party. So dense was the crowd which gathered around the *cortége*, that a strong force of police was necessary to clear the way; and on its arrival at the cemetery of St. Martin's, Pratt-street, there was a hostile demonstration on the part of the people who surged round the chapel in such numbers that the mourners were unable to get to their coaches, and were compelled to make their way homewards as best they could.

Another proof of Dr. Swiney's eccentricity had already been seen in the manner in which he communicated the terms of his will to the Society. One day, during the secretaryship of Mr. Arthur Aikin, a gentleman entered the office carrying a small parcel, which he requested permission to leave for the Society, at the same time stipulating that it was not to be opened until a letter should be received giving instructions as to its disposal. Years passed, and the mysterious parcel remained sealed. At length a committee was appointed to consider what should be done with it. Finally it was decided to open the parcel, which was found to contain a copy of Dr. Swiney's will. Efforts were then made to ascertain whether Dr. Swiney was still living, but in consequence of the extraordinary seclusion which he affected, all these attempts failed, and finally the matter was allowed to drop until 1844, when a letter was addressed to the Society announcing his death.

Dr. Swiney's name would probably have been forgotten long ago but for two bequests of £5,000 each. The first he left to the trustees of the British Museum for the establishment of a lectureship in Geology, the second to the Society of Arts for the purpose of presenting on every fifth anniversary of his death a silver goblet of the value of one hundred pounds containing gold coin to the same amount, to the author of the best published work on Jurisprudence. The prize was to be adjudged by members of the Society of Arts and the Fellows of the College of Physicians.

The will was proved on February 6th, 1844. In order to obtain a prize of artistic merit and worthy both of the testator and of the Society, the Council offered a prize of £25 for a design emblematical of Justice; but though the offer was kept open

three years and many drawings were submitted, the Committee appointed to consider them were unable to recommend any for the award. In these circumstances the Council commissioned Mr. D. Maclise, R.A., to make a design. This was approved by the Council on March 11th, 1850, and the cup has been executed from it by Messrs. Garrard and Co. ever since.

In 1894 the question of providing a new design was considered, and the Council resolved again to offer a prize of £25 to all students of schools of art in the United Kingdom. A large number of models and drawings were submitted, but the Council, although they awarded consolation prizes to three of the competitors, did not consider any of the new designs an improvement on the old.

According to a contemporary description, "the cup was designed in the French Renaissance style of the eighteenth century, decorated with boldly embossed bulbs, between which is conventional scroll and *fleur de-lis* ornament. The subject of the bas-relief on the body is 'The First Trial by Jury,'* *temp.* Henry II., A.D. 1176. 'By this law the Justices who represented the King's person were to make enquiry by the oaths of twelve Knights, or other lawful men of each hundred together with four men from each township, of all murders, robberies, and thefts.' (*Vide* 'Pictorial History of England.') The figures on the base of the cup represent male and female figures bound together by fetters, and those surmounting the cover symbolize Justice with the scales, on her right hand an Angel pleading for mercy and on her left an officer holding a sword for carrying out the stern sentence of the law. Other attributes distributed about the cover of the cup are manacles, fetters, stones, &c."

* The origin of Trial by Jury is wrapped in mystery, but it is certainly of much more ancient date than that assigned to it here, the only basis for which appears to be the fact that, under an enactment of Henry II. the defendant in certain actions relating to freehold or status was enabled to decline trial by combat and choose trial by assize.

THE DANISH EGG INDUSTRY.

The egg industry in Denmark has been stimulated by the growing demands of the British markets, which in the years 1907 and 1908 consumed annually about 3,800,000 great hundreds of Danish eggs, valued at £1,800,000. Poultry breeding in Denmark is carried on generally on a small scale, and is confined to small farmers, who supply local customers or hotels without any system in placing their goods on the market. It may be said that the fattening of fowls is sacrificed to the production of eggs, and this has determined the breeds of hens used. The original breed of Danish hens, though hardy and good layers, produced small eggs. The American Consul-General at Copenhagen says that to remedy this they have been crossed with other breeds, of which the Plymouth Rocks, Wyandots, Cochins, and Orpingtons are preferred. The eggs are pickled in a solution of lime during the months of April and May, and are offered for sale from October to February. Before and after pickling they are subjected to a critical test by electric light. The sale of eggs in Denmark for home consumption is increasing, and the business is in the hands of traders, who may, or may not, be members of the three associations now making an effort, through experiments, exhibitions, and reports, to ensure progress and co-operation. Of these Associations, by far the most important is the Co-operative Egg Export Association, of Vejle, through which, with a few large export firms, an export business is done which, in 1897, amounted to about £650,000, increasing to £1,370,000 in 1906. As this trade is chiefly with Great Britain it is with a view to the maintenance of good prices that the examination, sorting, packing, and shipping of eggs is carefully carried out. This Association has more than five hundred districts, with a membership of about forty thousand, from whom eggs are collected. Producers must deliver eggs to the district stations, each egg stamped with the member's number. No member is allowed to keep eggs, except for the immediate use of his family. If it is discovered at the sorting and examination at Vejle that kept eggs are delivered subsequently the offender can be traced by the stamps on the eggs. At the first offence he is warned, on the second occasion a fine is imposed, and on the third, he is expelled from the Association. At the district stations the eggs are re-stamped and forwarded to packing stations, of which there are ten in different parts of the country, principally at the ports. Here the eggs are carefully examined by electric light, restamped "D.C.E.A." if good, and forwarded to the packing room, where they are sorted according to size, as this is a matter of importance to the retail trade. They are then packed in cases. All bad eggs are rejected and traced by the stamps back to the seller, who is fined. In this way the Danish association has been able to gain the reputation for handling good stock. This co-operative system has the obvious advantage of dispensing with the expense of dealing through middlemen. It has built up one of the principal businesses of the country, and produced a superior quality of eggs for export.

A NEW PHONOGRAPH.

The methods for recording sound, have reached a higher stage of perfection than those employed for its reproduction. The chief difficulty encountered in the present system of reproducing conversation, and especially music, from phonographic and similar records, is caused by the friction of the needle resting upon a surface of the rapidly revolving disc or cylinder. This introduces a more or less noticeable buzzing or rumbling sound, which interferes materially with the clearness of musical notes or spoken

words. Numerous attempts have been made to overcome this unpleasant accompaniment. In none of the devices hitherto brought forward has complete success been attained, since all involved the factor of friction as the fundamental means of transmission. The American Consul at Chemnitz says that in a recent number of the "Deutsche Musikwerk Industrie," a German inventor describes a newly patented instrument in which friction is completely avoided. It combines the leading elements of the phonograph and the siren. The novel and essential feature is the substitution of a current of compressed air, for the needle or stylus of Edison's invention. In a siren, openings of various sizes allow the production of all musical notes with any desired degree of intensity or length. In the new instrument, perforations in the disc of a siren are replaced by incisions on the surface of a large record cylinder. A second perfectly smooth cylinder rests close upon the surface of the first cylinder, and revolves in unison with it as the two cylinders are set in motion. A constantly varying succession of minute openings between their surfaces is presented, due to the incisions on the record cylinder. When a powerful blast of compressed air is directed upon the line of contact between the two cylinders, at such an angle as to be an exact tangent to the surfaces of both, sounds are evoked identically as in the case of an ordinary siren. It is possible to communicate signals and even words, which can, it is said, be readily heard miles away. It is already evident that a field of usefulness is open to this new invention as an adjunct to the equipment of sea-going vessels. Its availability for musical purposes has not yet been tested sufficiently to determine whether it can successfully vie with the gramophone, phonograph, &c., or even replace them. The cylinders thus far employed are about ten times as large as ordinary phonographic cylinders, and this fact renders the instrument necessarily somewhat clumsy. The requirement of a current of compressed air may also militate against a widespread domestic use, although such a current can be supplied by a comparatively inexpensive attachment to a water tap where the water supply is under considerable pressure.

HOME INDUSTRIES.

Railway Amalgamation.—The Great Northern, Great Central, and Great Eastern Railways Amalgamation Bill has been sent to a Hybrid Committee, which will have power to consider not only this one Bill, but the whole case for and against amalgamation in the public interest. This was the suggestion of the President of the Board of Trade, and induced the House of Commons, by a narrow majority, to read the Bill a second time. The opposition of the traders, who see in it an attempt to deprive them of the guarantees which they have enjoyed under the competitive *régime* without offering them any compensating advantages, or setting up any acceptable alternative policy, has been strenuous and sustained. Hitherto the railways of the kingdom have been worked under a system of what may be called qualified competition—that is, competition subject to Parliamentary objections and statutory maximum rates. Whatever may have been the case in the past, the present position of the railway industry is anything but satisfactory. The cost of railway working has been rapidly rising, both actually and in proportion to the growth in receipts, while the return upon capital has been steadily falling, notwithstanding a very great increase of traffic and of gross earnings. There is dissatisfaction on all sides. Railway shareholders complain that their return is inadequate; traders complain that rates are too high and facilities insufficient; directors complain that they cannot raise capital for even railway purposes—during last year only forty-five miles of new railway were constructed in the whole country; workmen complain that they are under-paid and over-worked. The directors contend that this unsatisfactory state of affairs is largely due to their having to pay excessive prices for land and property; to the undue burden of rates; and to the fulfilment of obligations placed on them by Parliament which greatly diminish their earning capacity. And others would add to these explanations excessive dividends in past times, the charging to capital account of much expenditure which ought to have been met out of revenue, and large expenditure upon competitive services not required and which could not be expected to pay. The question for the House of Commons and the country is whether the remedy for the present discontent is to be sought in amalgamation or in other directions. Amalgamation is no new thing. Ever since railways came into being there have been instances of amalgamation. The early railways were short lengths of line, afterwards amalgamated into great trunk systems. Since then—for the last forty years—the country has possessed a number of powerful railway systems, each to a large extent confined to its own region, but touching one another at various important points, with the result that at the great centres of industry there has been effective competition. The suggestion underlying the present Bill is that it is necessary to do away with competition. But there is the alternative of what may be called free trade in railways. The railways from the outset have been hampered by Board of Trade regulations, many of them needlessly restrictive, and they have been compelled to run trains at non-paying prices for the supposed benefit of working men, a most questionable insistence from many points of view. Again, the railway companies are unfairly burdened by local authorities in the shape of rates. If they were relieved of these burdens, in so far as they are unjust, and left to themselves to do the best they can in competition with one another, subject to some strong central authority empowered to act on its own initiative in defence of the public

interest, it might well be that the present troubles would disappear, or be greatly minimised. In this country we have one great amalgamation at work, namely, that of the South Eastern and Chatham lines, and the result has been extremely disappointing. Instead of mending things have gone from bad to worse, not only from the public, but from the shareholders' point of view. The other illustration within the United Kingdom of the working of amalgamation is to be found in Ireland, where the Great Southern and Western of Ireland effected a similar amalgamation with very similar results.

London Passenger Transport Companies. — It may be claimed for London that it has the best system of passenger transportation in the world, but great as is the benefit to the public of these improved means of migration, those who have found the capital are left lamenting. Suicidal competition has killed profits. With the exception of the Great Northern, Piccadilly, and Brompton system none of the transport companies, as a result of last year's working, could pay anything on the ordinary capital, and in the case of the company mentioned, the distribution was only ½ per cent. *The Times* has published an interesting analysis of the results of working, during 1908, of the various companies which provide travelling facilities for London, including the London United Tramways and the London General Omnibus Company. Roughly, a capital sum of £57,500,000 was employed, of which £25,400,000 was in the form of loan and preference stock, receiving a fair interest, whilst, with the exception of the Central London Railway Company, some £32,100,000 of ordinary and other capital, went unremunerated, or received only a very trifling dividend. The actual profit divisible on this £32,100,000 was only £163,253, and even this was rather abnormal owing to the Franco-British Exhibition, which, it is estimated, gave £50,000 profit to the Central London, £20,000 to the Metropolitan, and £10,000 to the District Company. Deducting this special revenue, the divisible profit on ordinary capital was only equal to a dividend of ¼ per cent., and this in return for moving nearly 578,000,000 passengers.

The Necessitous Mothers Bill.—Encouraged by the success of the Bureau de Bienfaisance, at Ghent, and the School for Mothers, at St. Pancras, and moved by the urgent need for action from the national standpoint, Mr. Robert Harcourt, M.P., has introduced a Bill called the Local Authorities (Necessitous Mothers) Bill, which has for its object the lessening of infantile mortality by properly feeding, instructing, and supervising poor and ignorant mothers. At Liverpool, St. Helen's, Ashton-under-Lyne, and elsewhere, the municipalities facilitate early bottle feeding, by a supply of humanized milk. Mr. Harcourt would feed the mother that she may be able to suckle the child. What may be done in this direction, is indicated by the success of the School for Mothers, in St. Pancras. As late as 1904 that borough was one of the worst in London in respect of its infantile death-rate. Then its Medical Officer of Health, Dr. J. F. J. Sykes, and others, began an educational campaign on behalf of breast feeding. The consequent fall in the infantile death-rate has been very remarkable. It has been brought about by a judicious mixture of feeding and teaching. The Mothers' Welcome not only feeds the mothers, it gives them practical instruction in hygiene, management, and cooking, and in clothing, minding, and management of their infants. Mr. Harcourt's Bill, if it became law, would enable English local authorities to do the same. Entirely permissive, the Public Health Authority would be enabled, if it chose, to provide food, advice, and other assistance to poor mothers from a medically defined point before the birth of their children until six months after their births. It would be able to impose terms on the mothers as conditions of their receiving assistance—for example, that they shall suckle their infants, or attend class, or refrain from going to work, and it would not be allowed to impose more than a penny rate for the purposes of this work. Obviously there are great difficulties in the way of the smooth working of a scheme of this kind, not the least being the dire necessity which so frequently compels a woman to return to work before she is physically fit to do so, and frequently in violation of the Factory Act which forbids a woman to work for a month after her child's birth. It is not likely that Mr. Harcourt's Bill will become law this year or next, but its introduction is a sign of the times, and the growing recognition of the truth that if the physical health of the nation is to be preserved, or restored, greater care must be taken to ensure that the children of the poor, as of other classes, are born into the world healthy, and properly treated and fed in infancy.

The Poisons and Pharmacy Act.—On April 1 this Act, which is the outcome of the recommendations of the Departmental Committee appointed in 1901 to consider whether there was need for alteration in the statutory provisions governing the sale of poisons, came into force. The complaint had been made by farmers and gardeners that owing to the restriction to chemists of the sale of poisonous materials used in agriculture and horticulture, the existing provisions for the distribution of such preparations were insufficient; the Committee endorsed these complaints, and the Act is intended to meet them. It empowers local authorities to grant licenses to nurserymen, florists, seedsmen, and others, to sell sheep dips, weed killers, and insectitides, containing arsenic and nicotine, provided the reasonable requirements of the public with respect to the purchase of such poisonous substances are not already satisfied in the district in question. The license to sell may not exceed 21s., and in the case of renewal 2s. 6d. Whilst relaxing the regulations governing the sale of agri-

cultural and horticultural poisons, the Act seeks to prevent the misuse of other dangerous substances, such as vitriol, nitric acid, and spirits of salts, by making it unlawful to sell them unless the containers are labelled with the name of the substance, the word "Poisons," and the name and address of the sellers. The Act also requires that every shop where the business of a chemist and druggist is carried on shall be under the management of a properly qualified person, whose certificate of registration shall be exhibited in the shop, and the designation of "Pharmacist" is exclusively reserved for persons who are registered under the Pharmacy Act.

The Factory Acts and Australian Competition.—English clothing manufacturers, who have to work under the regulations of the Factory Acts, are complaining that while the shipments to Australia are affected by Commonwealth tariff legislation something like the sweating system is growing in the large Australian towns. And the complaint seems to be well founded. The Queensland Director of Labour, investigating a complaint from Melbourne as to low rates of wages and unfair competition in the Brisbane clothing trade, has reported that home workers are paid 1s. 6d. to 3s. a dozen for finishing trousers, 1s. 9d. to 3s. a dozen for shirts, and 1s. 4d. to 1s. 9d. a dozen for under-flannels.

OBITUARY.

Sir DONALD CURRIE, G.C.M.G.—On the 13th inst. Sir Donald Currie died at the Manor House, Sidmouth, in his 85th year. Born at Greenock he entered the shipping office of a relative in his native town when 14 years of age, and four years later he left for Liverpool to become a clerk in the office of the Cunard Company. He rose rapidly in this service until he was promoted to the managerial staff in 1856; but having long aspired to become a shipowner on his own account, he resigned this post in 1862 and established the Castle Line of sailing ships plying between Liverpool, London, and the East Indies. Ten years later he started the famous Castle Line of steamers sailing between England and South Africa, which in 1900 was amalgamated with the Union Line under the name Union-Castle. As soon as the Cape became the centre of his energies, Mr. Currie, with characteristic thoroughness, set himself to study South African interests, and he soon acquired such a reputation that his assistance was sought in connection with the settlement of the diamond fields dispute and the Orange Free State boundary question, and his services were rewarded in 1877 by the conferment of the honour of C.M.G. In 1881 he was made K.C.M.G. for the assistance which he rendered in transporting troops to South Africa at the time of the Zulu war, and especially in connection with the relief of Ekowe. Sixteen years later, at the Diamond Jubilee, he was raised to the honour of G.C.M.G.

Sir Donald, in spite of the energy which he devoted to his shipping business, found time for many other interests. He sat as M.P. for Perthshire from 1880-1885, and for West Perthshire from 1885-1900. He was a great admirer of Mr. Gladstone, and although on the occasion of the Home Rule split he declared himself a Unionist, he remained on terms of intimate friendship with his former leader. He was also a keen sportsman, delighting until the last year or two in the arduous pleasure of deer-stalking, and his yachting cruises have become almost historical. He had a great taste for pictures, possessing an excellent collection of works by old and modern masters; and his public benefactions were muificent, the most striking being a gift of £100,000 to University College, London, £20,000 to Queen's College, Belfast (in which town he received his own early education) and £25,000 to the University of Edinburgh).

Sir Donald Currie had been a member of the Royal Society of Arts since 1875. He took part in discussions at ordinary meetings on more than one occasion, and in 1880 he was awarded the Fothergill Gold Medal "for the improvements he has introduced into his passenger steamers, having for their object the prevention of loss of life at sea from fire or accident."

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

PAPIN'S DIGESTER.—Can any reader of the *Journal* refer me to a contemporary description of Papin's "Digester?" I have some recollection of having read a very full and interesting account of some experiments made in London by Papin himself with the first apparatus he constructed, but cannot put my hand upon the original description.—X. Y. Z.

VELLUM.—What is the best method of removing stains from the vellum bindings of books?—LIBRARIAN.

JAPANESE WALTZING MICE.—"Medicus" states "Excessive inbreeding of the ordinary species

mice will bring about a similar result." Will he kindly give me his authority for this? Has he tried the experiment himself, or does he know of any case in any work of authority?—ALFRED H. HUTH.

GENERAL NOTES.

THE ROYAL DRAWING SOCIETY.—The twentieth annual exhibition will be held, by permission of the Court of the Fishmongers' Company, in Fishmongers'-hall, Adelaide-place, E.C., from April 16th to 28th.

SPRING MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The semi-annual convention of the American Society of Mechanical Engineers will be held in Washington, D.C., from May 4-7. During the convention there will be professional sessions devoted to steam turbines, the specific volume of saturated steam, stay-bolts, gas-power engineering, oil well pumping, &c. The entertainment features include a reception by the President of the United States, an exhibition drill by troops at Fort Myer, and possibly exhibition flights of a dirigible balloon and an aeroplane.

COMPANIES AS TRUSTEES AND EXECUTORS.—It may be taken as certain that insurance companies and banks will cater more and more for the work of trustees and executors opened to them by recent legislation. The first annual report of the Public Trustee states that during 1908 he became responsible for 425 trusts, and at the close of the year was engaged in administering 325, these representing a capital value of £2,095,000. It is estimated that the capital value of unmatured wills under which the Public Trustee has been informed that he is expected to act, together with the value of the trusts he is now engaged in administering, is in excess of £20,000,000. These figures indicate great possibilities. The system of appointing private trustees has proved in very many instances a failure, and now that other facilities are available its revival is not likely to be of very long duration. But there is no good reason why all, or most, of the business should go to the Public Trustee. For some reasons the public are likely to prefer leading banks and insurance companies willing to do the work. The security is practically as good.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

APRIL 28.—"The Resources of the Peruvian Andes and Amazon." By C. REGINALD ENOCK, F.R.G.S. SIR CLEMENTS ROBERT MARKHAM, K.C.B., D.Sc., F.R.S., will preside.

MAY 5.—"English Furniture Design and Construction." By PERCY A. WELLS.

MAY 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 29.—"The Problem of Indian Labour Supply." By SELWYN HOWE FREMANTLE, I.C.S. The RIGHT HON. VISCOUNT MIDLETON, late Secretary of State for India, will preside.

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India).

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

APRIL 20.—"The Road to South African Union." By the HON. CHARLES GIDEON MURRAY. LORD BRASSEY, G.C.B., D.C.L., LL.D., will preside.

MAY 18.—"Canada as a Field for British Investment." By J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

LECTURE I.—APRIL 26.—*The principles of dynamic support*—The action of an inclined plane—The law of pressure reaction as a function of velocity—The law of pressure as a function of angle—Frictionless flight—The law of power expenditure as based on the laws of the pressure reaction—The laws of pressure reaction and power expenditure quantitatively considered: a discrepancy—The dipping front edge and its lesson—Cyclic motion in its relation to the supporting reaction—Direct evidences of cyclic motion—The quantitative treatment on the hypothesis of a

cyclic component—The power expenditure under real conditions—Skin friction, its nature and magnitude—Skin friction as affecting power expenditure—Skin friction and other factors as limiting the wing area—Aeroplane *versus* pterygoid form—Meaning and influence of *aspect*—Importance of aspect ratio—The gliding angle, as measure of resistance—The minimum gliding angle as a function of the velocity of flight—The coefficient of skin-friction and the aspect ratio as affecting the value of the minimum gliding angle—The angle of inclination as related to the minimum gliding angle—The pressure proper to least resistance—The theory of screw propeller efficiency—Comparison of theoretical results with measurements of birds, flying machines, &c.—Controversy as to influence of skin-friction—Conclusions as affecting the problem of mechanical flight.

LECTURE II.—MAY 3.—*The principles of stability*—The simple glider—The ballasted aeroplane—Form of the flight path as observed—The flight path as plotted from the equation—The phugoid chart and its teaching—Changes of amplitude of the phugoid curve and influences that lead to such changes—Conditions of flight path, stability and the equation of stability—Effects of propulsion on stability—Influence of the flexibility of the aerofoil—Lateral stability—Rotative stability—The stability of birds and of flying machines in practice—Flight path stability desirable but not essential to flight—Steering in altitude and azimuth—Gyroscopic couples—The boomerang—The gyroscope as an aid to stability.

LECTURE III.—MAY 10.—*The Flying Machine.*—The function and uses of the flying machine—Possible types—The conditions to be fulfilled as defining the type—The need for high velocity—The difficulties of high velocity—The horse-power problem—Motors for flying machines and the conditions governing their weight—Fuels available and the relative importance of fuel economy—Propulsion and the propeller—The use of gearing—The limitations of flight as due to the mode of propulsion—Other modes of propulsion—Wing flapping and its efficiency—Soaring—Starting and alighting—Questions of design and construction—Steering and steering mechanism—Flying at a height—The advantages and disadvantages of altitude—Types of flying machine in practice—The future of flight—The flying machine as a mode of locomotion, in peace and war.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 19...British Architects, 9, Conduit-street, W., 8 p.m. Mr. W. E. Riley, "The Architectural Work of the London County Council."

Victoria Institute, 1, Adelphi-terrace, W.C., 4½ p.m. Rev. A. Galton, "Modern Christianity in France, with Reference to the Present Movement."

TUESDAY, APRIL 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Hon. C. G. Murray, "The Road to South African Union."

Junior Institute of Engineers, Royal United Service Institution, Whitehall, S.W., 7½ p.m. Mr. C. H. Smith, "Systems of Electrical Power Distribution."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Brain in Relation to Righthandedness and Speech." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. C. T. Purdy, "The 'New York Times' Building."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. Munia Keene, "Racial Types in South Africa, and the Flora of the Country."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Miss E. V. Jenkins, "Canada Illustrated by Canadian Artists."

WEDNESDAY, APRIL 21...Meteorological, 25, Great George-street, W., 7½ p.m. 1. Mr. Baldwin Latham, "Percolation, Evaporation, and Condensation." 2. Rev. José Algué (S.J.), "The Meteorological Conditions in the Philippines, 1908."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. Heron-Allen, "The Recent and Fossil Foraminifera of the Shore-sands of Selsea Bill, Sussex." 2. Mr. E. J. Sheppard, "The Disappearance of the Nucleolus in Mitosis."

Auctioneers, 34, Russell-square, W.C., 7½ p.m. Mr. B. I. Breach, "The Practice of Compensation as affecting the Valuer."

THURSDAY, APRIL 22...Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. Paterson, "Aspects of Applied Aesthetics: (1) How a True Art Instinct may be Best Developed."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

Historical, Lecture-hall, Field-court, Gray's-inn, W.C., 5 p.m. Miss Leonora de Alberti and Miss A. B. Wallis Chapman, "English Traders and the Inquisitions in the Canaries during the Reign of Queen Elizabeth."

Mining and Metallurgy, Geological Society's Rooms, Burlington-house, W., 8 p.m.

FRIDAY, APRIL 23...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. Siemens, "Tantalum and its Industrial Applications."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. J. M. S. Culbertson, "The Development of Hydro-Electric Power Schemes: with special reference to Works at Kinlochleven."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Prof W. H. Bragg and Mr. J. L. Glasson, "A want of Symmetry shown by Secondary X-Rays." 2. Mr. C. A. Sadler, "Transformations of X-Rays." 3. Prof. T. R. Lyle, "Theory of the Alternate Current Generator."

African, Trocadero Restaurant, Piccadilly, W., 7½ p.m. Colonel H. E. Rawson, "Some Experiences with Native Tribes in South Africa."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Address by the President (Mr. J. A. F. Aspinall).

SATURDAY, APRIL 24...Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. T. Günther, "The Earth Movement of the Italian Coast and their Effects." (Lecture I.)

Journal of the Royal Society of Arts.

No. 2,944. VOL. LVII.

FRIDAY, APRIL 23, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 26, 8 p.m. (Cantor Lecture.) F. W. LANCHESTER, "Aerial Flight." (Lecture I.)

WEDNESDAY, APRIL 28, 8 p.m. (Ordinary Meeting.) C. REGINALD ENOCK, F.R.G.S., "The Resources of the Peruvian Andes and Amazon."

THURSDAY, APRIL 29, 4.30 p.m. (Indian Section.) SELWYN HOWE FREMANTLE, I.C.S., "The Problem of Indian Labour Supply."

Further particulars of the Society's meetings will be found at the end of this number.

QUESTIONS AND ANSWERS.

In view of the fact that the Royal Society of Arts includes amongst its members authorities on almost every branch of human knowledge, it has been suggested that some space in the *Journal* should be devoted to correspondence of the "Notes and Queries" order. Readers in search of information are, therefore, invited to make their wants known in the hope that they may be assisted by their fellow members. Further particulars will be found under the heading "Questions and Answers, on p. 465.

COLONIAL SECTION.

On Tuesday afternoon, April 20th, the Hon. CHARLES GIDEON MURRAY read a paper on "The Road to South African Union." SIR GODFREY YEATMAN LAGDEN, K.C.M.G., presided.

The paper and discussion will be published in the next number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, April 6th; the Right Hon. SIR WEST RIDGEWAY, G.C.B., G.C.M.G., K.C.S.I., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that no one interested in Ceylon could fail to know that the name of Ferguson, in the person of the author and of his uncle, both of whom had been decorated by their Sovereign, was intimately associated with the prospects and progress of the island. For nearly half a century Mr. Ferguson had laboured in the cause of Ceylon, indeed it had been a labour of love with him. As editor of the principal papers of the island, and of the "Ceylon Directory," which was a mine in which every Governor delved and sought for information and enlightenment; as a lecturer in the United Kingdom and the United States of America; as a member of the British Association, in every branch of which he took great interest, so far as it could be made to serve the interests of Ceylon; and as a member of the Legislative Council, the author possessed eminent qualifications for writing a paper on the industries and material progress of the island.

The paper read was—

CEYLON: ITS INDUSTRIES AND MATERIAL PROGRESS.

By JOHN FERGUSON, C.M.G.

Wellnigh ten years have elapsed since I had the privilege of reading a paper before this Society on "Old and New Colombo," with Sir Thomas Sutherland, G.C.M.G., of the P. and O. Company, in the chair: an occasion which, as the late Sir Charles Kennedy declared at the time, constituted a successful inauguration of the Colonial Section of the Royal Society of Arts. I have now been asked to supplement that paper with some account of the industries and recent material progress of Ceylon, and I am honoured by having for Chairman one of the ablest and most successful of the Governors of this colony in modern times.

Introduction.

By way of introduction, I should mention that the island has an area of 25,000 square miles, a little less than Ireland, with a population slightly exceeding 4,000,000, of whom the major portion are Sinhalese, supplemented by Tamils, Arab descendants, Malays, Burghers, and Eurasians, while the colonist or European community does not number more than 6,500, including men, women, and children. The principal towns are Colombo, the commercial and political capital, with some 185,000 people; Kandy, the whilom capital of the Kandyan kingdom, with 30,000; Point-de-Galle, once the great mail steamer port, but now comparatively insignificant in trade, with 40,000 people; Trincomalee, with the finest natural harbour in the island or in the East, but with no trade, little cultivation, and only 12,500 of population; Jaffna in the north, a great centre of Tamil agricultural industry, with 48,000 people; Batticaloa, another specially Tamil centre, with 11,000 people; and Newera Eliya, the sanatorium, 5,500. Then there are several minor but interesting provincial capitals and towns apart from what are known as the ancient "buried cities" of Anuradhapura and Polonaruwa, long the seats of native government, large population, and extensive industry; but now chiefly remarkable for the ruins of palaces and temples; and made readily accessible of recent years by railway communication, and by motor-cars travelling over good roads.

History.

Before turning to the text of my discourse, I may just mention that authentic history and settled government in the case of Ceylon may be said to date from about 500 B.C., and that native rule, under kings of diverse and often opposing races, and marked by frequent wars and much disturbance, lasted for wellnigh 2,000 years, before Europeans, in the persons of the Portuguese, first appeared, and gradually took possession (not without much opposition) of the coast districts, west, south, east and north. These they held for 150 years, but though the attempt was frequently made, they never were able to conquer the Kandyan Kingdom, the strongholds in the hill country being comparatively inaccessible through the absence of roads. About the middle of the seventeenth century the Dutch ousted the Portuguese, and in their turn held the maritime provinces for 150 years, until relieved by the British in 1796, who finally took possession of the whole island, not by right of conquest, but through amicable negotiations with the Kandyan Chiefs, who practically dethroned their last king, a monster of cruelty, and handed him a prisoner to the English Governor while arranging for the transfer of their country to the British Crown on certain specified conditions. Ceylon has, therefore, been administered as a British colony, the maritime provinces for 112 and the whole island for 93 years.

Description.

In attempting any general description of the island, I always think of the opening sentence in Sir Emerson Tennent's monumental work which runs as follows:—"Ceylon, from whatever direction it may be approached, unfolds a scene of loveliness and grandeur unsurpassed, if it be rivalled by any land in the universe." From the coconut palms bending over the sandy shores until they almost kiss "the league-long rollers" of the Indian Ocean, up to the top of its highest mountains, Ceylon is one vast continuous botanic garden, full of plants, flowers, ferns, and orchids, only known to the possessors of extensive conservatories in temperate regions. But my task to-day is not to tell of what is interesting to the botanist, zoologist, or lover of natural history generally; to the sportsman, historian or archæologist; but rather to describe briefly the principal industries and the material progress of recent years.

Rice-growing and Irrigation.

Ceylon is pre-eminently dependent on agriculture, and the cultivation of rice, the staple food of the people, was naturally one of their earliest occupations which in time—with the fostering of irrigation and construction of immense tanks, lakes and inland seas under autocratic as well as enlightened native monarchs—developed a great industry sufficient to maintain a considerable population. This was chiefly on the north-central plains, where now, as the result of prolonged continuous wars between the Sinhalese and Tamils, the country is almost entirely covered with jungle and most thinly populated—one or two persons to the square mile. For the past 400 years, at least, Ceylon has been more or less dependent on India for a proportion of its food supply, and, notwithstanding much attention given and much money spent by the British Government in fostering and restoring irrigation works, since the develop-

ment of the planting enterprise in coffee, tea, &c., during the past 70 years by Europeans, and the great increase in trade and in urban population, this dependence on India for rice supplies has been greatly emphasized.

During the past 50 years special attention has been given by successive British governors, beginning with Sir Henry Ward, to the encouragement of rice-growing by the natives, and, altogether, not less than a million and a quarter pounds sterling from revenue and loans have been devoted to irrigation, the largest outlay having been during the administration of Sir West Ridgeway. Much benefit has undoubtedly resulted not only in affording means of industry and subsistence to a rural population in remote districts, but in greatly improving the sanitation and the health of the people through providing a good water supply, the clearing of low jungle, and the inducement of regular cultivation. But at the same time it must be confessed, little or no progress has been made towards rendering Ceylon independent of India or Burma for its rice supply. For whereas 40 years ago the total annual importation of rice was 4,406,216 bushels, the equivalent, it was estimated, of less than half the consumption of the island, now (for 1907)* the import has risen to 10,697,254 bushels, and is equal to quite three-fifths of the total consumption. Be it remembered, however, that in the meantime the population has nearly doubled, and that the total cultivation on plantations has quadrupled in the same time.

CINNAMON.

The next oldest cultivation to rice must be that of cinnamon, which is undoubtedly indigenous to the island, and which, as grown in Ceylon, affords the finest spice of its kind in the world. The trade was first developed by Arab voyagers (the "Moormen" of Ceylon history). In the time of the Emperor Augustus Ceylon cinnamon was sold in the streets of Rome at the equivalent of £5 sterling per pound. Now the very best is to be got in Mincing-lane for 2s. 6d. per pound. The Portuguese and Dutch chiefly valued Ceylon for its cinnamon, the latter also getting a good deal of pepper from the vine which grew freely in the Kegalla and Matara districts. It is evident that the cinnamon shrub has been cultivated on the same light siliceous soil on the west coast of Ceylon (chiefly in the Negombo district) for over 2,000 years. The crops and exports have increased greatly within the past 20 to 30 years, but the profit is limited, since production is apt to outstrip the demand. Much of our Ceylon cinnamon goes to Spain for the flavouring of chocolate, and to the South of Europe generally for incense in the churches. The cultivation and preparation of the bark is purely a native industry.

* For 1908, the importation was below the average because of the scarcity and dearness of rice in India: but the current year shows a much increased import so far.

PALMS: COCONUTS, &C.

But far more important to the natives (and to many colonists) is our great industry in palm cultivation: coconuts chiefly, nearly all round the island, though mainly from Matara up the west coast to Puttalam, and all over the Negombo, Chilaw, and most of the Kurunegala districts—but also the palmyra palm in the north of the island; arecas in Kegalla and western districts; and kitul (*Caryota urens*) and the grand talipot (*Corypha umbraculifera*), peculiar to Ceylon, in the western interior. The coconut probably floated to Ceylon from its habitat in the Eastern Archipelago* before the Christian era, and its spread along the coast, at the instance of successive native rulers, is related in the "Mahawanso." But until 100 years ago coconuts were used solely to provide food, and light, through their oil, for the natives. The first cargo of coconut oil shipped from Ceylon to Europe was in 1818; but no special impetus was given to the trade till about fifty years ago, when a great deal of planting took place, and mills on a large scale for expressing the oil were established in Colombo. Now, coconuts—through the manufacture of oil, of coir (the fibre), of desiccated coconut (for confectionery, &c.), and the shipment of copra (the dried kernel), of punac (the crushed cake for stock feeding) and of the nuts themselves—form one of the largest of Ceylon industries, and provide work (as well as a great deal of their food) for a large number of the people, the Sinhalese more particularly. The palmyra (*Borassus flabelliformis*)† also gives oil as well as sugar to the Tamils of Jaffna; the areca palm supplies the much-used betel-nut to the native, and a great deal is exported to India; and the kitul‡ or jaggery palm, also yields sugar, sago, and toddy wine to the Kandyan.

* See paper on the "Coconut Palm in Ceylon: Beginning of its Cultivation," by J. Ferguson, "Journal of the Royal Asiatic Society," Ceylon Branch, No. 57 of 1906.

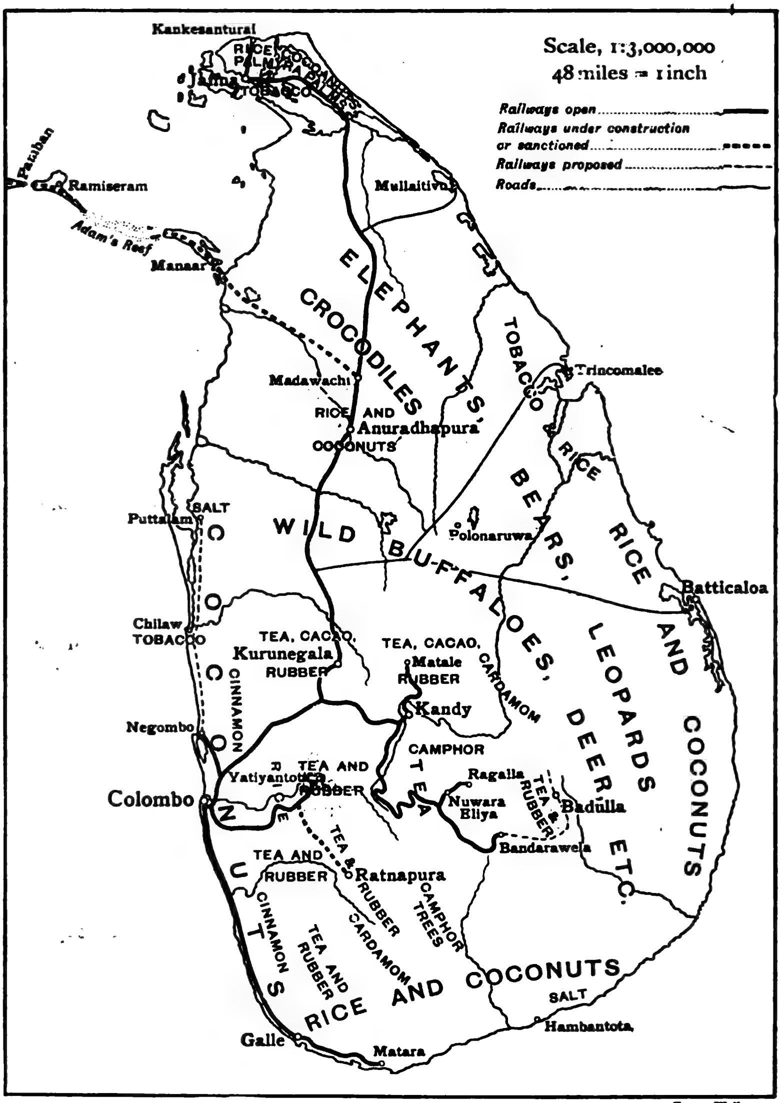
† Suited for a dry region, while the coconut requires more rainfall, as a rule.

‡ Emerson Tennent mentions a single kitul palm which was the main support of a Kandyan, his wife, and children.

Minor Products.

Pepper, tobacco, and cotton are minor but gradually growing industries among the natives, the cultivation of which, the Government, by experimental gardens and instruction, is endeavouring to extend. In growing and cinnamon leaf, timber, and fibres of various kinds also afford minor industries to the natives.

It must be mentioned that the coconut palm, which is supposed to flourish best on the seacoast, is successfully grown far in the interior,



Emery Walker sc.

Map of Ceylon.

vegetables and fruit of many kinds there is a considerable industry; but there is scope for much more, and some day there may be an export trade in canned pineapples and mangoes, and in banana flour, as now there is in desiccated coconut. Essential oils from citronella grass in the Matale, Kandy, Dumbera, Badulla, and other valleys, and also around towns in the drier districts, such as Anapapura. Indeed, Dr. Willis shows (see "Tropical Agriculturist" for January, 1909) that with irrigation this palm may be profitably cultivated right over

the North-Central, Northern, and Eastern districts wherever tanks are restored or are in working order. Only occasional watering is required. So also with cotton and tobacco cultivation, in which the Government experimental stations lead the way.

Stock-raising.

Another proposal made to utilise land in the North - Central Province has been for cattle stations, and a retired Ceylon proprietor (with experience of stock-breeding in England), after watching the cattle sent from Anaradhapura to the Kandy and Colombo markets, declared that if he were a young man he would readily invest capital in stock, provided the Government gave land on easy terms for a cattle and perhaps a sheep station. The encouragement is found in the fact that at present Ceylon imports cattle, sheep, goats, and poultry from India, and pays as much as £100,000 a year in this way, besides cold storage imports from Australia and Europe. The total number of live stock held by the natives of Ceylon is about 2 millions in cattle, goats, &c.*

Coffee: its Rise and Fall; and Modern Science in Tropical Agriculture.

Whatever may have been the case in the North-Central division 1,200 to 1,700 years ago, there can be no doubt that with its peculiarities of soil, rainfall, and climate, Ceylon (at least the South-Western portion) in the present day is far better suited to grow crops of leaf (tea), of various palm nuts (coco, palmyra, areca), of bark and spices (cinnamon, cardamoms, pepper, &c.), and now of the latex or milk of rubber trees, than it is for crops of cereals, whether of rice, maize, or dry grain. Accordingly, the modern progress and prosperity of Ceylon is usually dated from 1837, the year in which coffee-planting on its hillsides began to attract general notice; and, with many vicissitudes, ups and downs, this industry grew for 40 years until it reached a maximum annual crop of 1,000,000 cwt., worth between four and five millions sterling, grown on some 200,000 acres. Then came its downfall, due to an insidious fungus, which first appeared on the leaves of coffee in 1869, gradually weakening and practically killing the bushes, so that by 1890, the export had fallen to 90,000 cwt., while now it is about 1,000 cwt., grown on a few hundred acres. In 10 years Ceylon lost some 500 of its planters while the industry was practically ruined.* To shew the great progress of scientific agriculture within the past 30 years, the United States Agricultural Department and the Dutch at Buitenzorg, Java, leading the way (with Peradeniya, Ceylon, not far behind), I need only mention that Mr. Wilson, the then and present Minister of Agriculture at Washington (a Scotchman born), told me, in 1904, that he felt certain his staff could overcome the coffee, as they had baffled the orange, fungus, if they had encountered it in the "seventies;" while Dr. Treub in Java showed me last September a coffee plant† which had been improved and developed until

* Ceylon is, by nature, provided with a breed of cattle much better suited to its climate and roads than any that can be imported. Its small, compact, hardy, black cattle—now becoming extinct—are not only good for food, but they are the best for draft purposes, and should be preserved for the conveyance of rice and coffee to and from the interior. Now, although sheep do not thrive on the herbage of the southern provinces, and the leeches of the Kandyan country—except be above the elevation suited for the culture of coffee—prevent their being reared with success in the central province, no country has sheep better adapted to its climate than the Jaffna sheep are to the northern province; nor is the mutton of a well-fed Jaffna wether surpassed by that of any imported sheep. Jaffna sheep not being provided with wool to enable them to withstand the cold at Nuwera-Ellia, it may be desirable to import some with sufficient natural covering to keep them warm at such high elevation. But for no other purpose would it be necessary to import either cattle or sheep if the natives were properly instructed by English graziers in the improved method of breeding, rearing, and preparing the natural breeds of the island—the horned cattle for draft and the Jaffna sheep for the table. The money that has been fruitlessly expended on the importations of sheep from Aden, Bengal, Coimbatore, the Cape, and England, would have paid for a skilful English grazier's visit to Ceylon for the purpose of instructing the Ceylonese in his art.—*From Notes by James Steuart in* 1855 *after* 38 *years' residence in Ceylon.*

* How coffee utterly failed, to the ruin and disappearance of many of our planters, while many more bravely held to their posts, first planting cinchona, and then tea and cacao and cardamoms, and more recently India-rubber trees, camphor, and pepper, is a matter of modern history in Ceylon, and one full of romance as well as of illustrations of indomitable pluck and perseverance. Nothing ever recorded in the annals of agricultural or planting industry elsewhere in the world affords quite a parallel. For, as Sir A. Conan Doyle writes in one of his works: "Not often is it that men have the heart, when their one great industry is withered, to rear up in a few years another as rich to take its place, and the tea fields of Ceylon are as true a monument to courage as is the lion at Waterloo. My story concerns the royal days of coffee-planting in Ceylon before a pestiferous fungus drove a whole community through years of despair to one of the greatest commercial victories which pluck and ingenuity ever won." Let me say that the five million pounds sterling worth of coffee in the maximum year in the seventies, is now represented by tea, cacao, cardamoms, and rubber to a value of not less than £5,500,000—tea alone making up for the coffee—and with rubber this will soon exceed £6,000,000.—Ferguson's "Ceylon Illustrated." [Sir A. Conan Doyle on being referred to lately, writes:—"I remember the passage quite well; but can't say where it came from."]

† *Coffea robusta.*

it has proved to be immune so far as *Hemileia vastatrix* was concerned. Similar success has attended the work on cacao, tea, and palms of our Scientific Staff at Peradeniya, (first started on a liberal scale by Sir West Ridgeway), and so we no longer fear the diseases or enemies of our tropical products, whether tea, cacao, rubber, or palms; for the scientists have successfully overcome several of these already.

Cinchona: its Rise and Fall.

To go back to the dark days of "coffee," the brave men who stuck to their posts with *nil desperandum* as their motto, in the eighties, first tried cinchona plants to supplement or supplant their old staple, and these succeeded so well that in a few years the annual exports of the bark reached (in 1886) nearly 15,000,000 lbs., and so the price of quinine (which had been a guinea, and was for long 16s. an ounce) came tumbling down until it reached 1s. 6d. a lb.; and then the narrow margin would not pay the Ceylon planter for harvesting and shipping the bark, and the cinchona industry had to be abandoned in favour of Java, where a much richer (volcanic) soil and scientific guidance as to seed selection, enabled a far larger percentage of the alkaloid to be obtained from the bark and a cinchona growing industry to be continuously maintained, until Java now practically supplies nearly all the world's requirements.

Tea: its Permanent Success.

Most fortunately for the Ceylon planter, before his cinchona collapsed experiments in tea cultivation and preparation demonstrated a new and profitable product far better adapted to the climatic conditions and soil than ever coffee was or possibly could be.* The latter was an annual fruit crop (of berries), the failure of which meant a whole year's labour gone; while successive leaf crops from tea can safely be counted on for at least nine months of the year, the picking of the plant by the coolie women and children going on at intervals of eight to ten or twelve days. With wonderful rapidity did the planting of tea extend until the 10,000 acres planted by 1880 had increased to 220,000 by 1890, and now, in 1909, we have between 390,000 and 400,000 acres; but some 60,000 of these are interspersed with rubber trees, which, as the more valuable product, will gradually supersede the tea.

Cacao, Cardamoms, &c.

Many were the experiments made in different districts by different planters with other products besides tea when coffee and cinchona failed; for instance, with kola nuts, coca erythroxylon, West African palm nuts, pepper, &c. But the only products that made an appreciable mark were *Theobroma cacao* (the cocoa or chocolate of the breakfast table) and cardamoms, the spice so much used in their curries, &c., by the natives of India, and latterly growing in favour in Europe, Australia, and America. Cacao requires a comparatively rich soil and a low or moderate elevation, and has, therefore, to be confined to certain limited areas; whereas tea—one of the hardiest of plants—grows from seaside level to plantations at quite 7,000 feet altitude. Cacao after some years became affected by a fungus that threatened its extinction; but it was taken in hand by the plant Pathologist at Peradeniya, and under scientific direction the Ceylon planter has quite overcome this enemy, as he also keeps in check several minor troubles that from time to time affect his tea. There is no branch of agriculture all the world over without its drawbacks; the primal law applies more or less to all: "in the sweat of thy face shalt thou eat bread." Beginning with 300 acres in 1878, cacao now covers some 29,000 acres in certain suitable districts, chiefly around and north of Kandy. The spice, cardamoms, is also confined to a few districts, chiefly, however, because the world's demand is at present a limited one, not encouraging extended cultivation. The progress in planting has been from 1,200 acres in 1880 to 8,500 acres at the present time.

* It is pleasant to find a medical authority writing in favour of tea and coffee. In a recent volume, "Health and Common Sense," Dr. Woods Hutchinson says of tea and coffee:—"Few discoveries of the wit of man have," we are told, 'added more to the comfort and happiness of life and less to its miseries than tea and coffee.' They are a splendid 'introduction committee,' and are only injurious when there is an excess of tannin present. Most of the 'tea-poisoning' symptoms of the poor seamstress or working women are signs of starvation, not due to the tea which she can get, but to the lack of food which she can't afford. If you take either late at night they'll be likely to keep you awake; that's what they were introduced for originally—one by the bonzes of Thibet and the other by the monks of Arabia. The 'dyspepsia' attributed to them is due nine times out of ten to the food taken with them. No disease known to the medical profession is directly attributable to them."—*Home and Colonial Mail*, 1909. [This reminds me that linen-workers in the North o Ireland, working long hours, find good tea and potatoes the cheapest and most sustaining food; while French colliers also, with many hours' work daily, lived chiefly on coffee and potatoes.—J. F.]

THE STORY OF RUBBER-GROWING—A GREAT INDUSTRY.

The story of the latest addition to the planting industries of Ceylon — namely in rubber-yielding trees, particularly Para rubber —has recently been related by more than one lecturer, but especially by Mr. Herbert Wright, the author of the latest standard Manual for the rubber planter,* before the Royal Society of Arts. Suffice it for me to say that in 1876 the first plants of *Hevea* or Para rubber reached Ceylon from Kew (Mr. H. A. Wickham having brought them from Brazil) and were planted at Heneratgoda.† These parent trees are now 34 years old and are still flourishing. For some time considerable interest was taken by many Ceylon planters in rubber, but chiefly in the Ceara species, which disappointed expectations, and tea then proving a great success, rubber altogether got neglected save by a few fortunate individuals, who planted Para rubber, chiefly in the Kalutara district. At the instance of the late Dr. Trimen, of the Botanic Gardens, I compiled and published a "Manual for Rubber Planters" first in 1883; the second edition appeared in 1887, and the third in 1899. But comparatively few copies of these were utilised in Ceylon, most of them going to the Straits and Malay States, where, in consequence of the failure of Liberian coffee, more general attention was given to Para rubber than in the case of Ceylon; and although of late years our planting has approximated to that of the Malay States, still there is a far larger proportion of mature trees in the latter than in our island. That is shown by the much larger export up to date from the Malay States. But it is quite possible that after some years the exports from the two countries may begin to approximate more closely; for the area planted with rubber in Ceylon (180,000 acres) was, until lately, in excess of that planted in the Malay States. At the same time, it is quite a question whether the conditions of climate are not, on the whole, more favourable in the Malay Peninsula. On the other hand, we may be quite sure that the utmost justice will be done in liberal as well as judicious cultivation, harvesting and preparation of this valuable product in the first of Crown Colonies, whose planters have so long acquired the reputation of leading the world in everything connected with tropical agriculture. Only eleven years ago (1898), the area planted with rubber-yielding trees in Ceylon was but 750 acres; but three years after, this was increased to 2,500, and by the middle of 1904 to 11,000 acres. Since then the progress has been very rapid. By the middle of 1905, the returns showed close on 40,000, and a year later over 103,000 acres; while in August, 1907, this was increased to 146,000; and on 31st July last (1908), the figures returned by the planters for the Directory worked out to 180,000 acres. At the same time good authorities consider that a certain limited percentage of this area, injudiciously planted, is not likely to come to maturity; but further planting has gone on since, and is still going on, so that 180,000 to 200,000 acres may safely represent the industry as at present in Ceylon. Last year the export was 407½ tons, against 1,413 tons from Malay States, and about 221 tons from Sumatra, Johore, &c. (worth together probably £900,000); while it is estimated that in 1912, Ceylon may give 3,000 tons (worth at 3s. 6d. per lb., say £1,170,000), the Malay States, 7,500 tons (worth £2,925,000), and all Southern Asia perhaps 12,000 to 13,000 tons (£5,070,000).* I submit these figures,

* "Para Rubber," 3rd edition by Herbert Wright; published at *Observer* office, Colombo, and at 37, Shoe-lane, E.C.

† INTRODUCTION OF HEVEA TO THE EAST.—It has always been generally understood that the first introduction of *Hevea brasiliensis*, the Para rubber tree, to the East was in 1876, when a consignment of rubber plants came to the Peradeniya Botanical Gardens authorities in Wardian cases, the plants being those raised at Kew from the seeds brought over from Brazil by Mr. H. A. Wickham. This, however, is not really the case, for the first *Heveas* were sent to the East 3 years previously in 1873. Our authority for this is Colonel Prain, Director of the Kew Botanic Gardens, who, in response to a letter on the subject, writes:—"Regarding the introduction of *Hevea brasiliensis* to the East, I take pleasure in enclosing a copy of a memorandum prepared from the entries in the inwards and outwards books which will explain exactly how this matter stands. You will see that although the first distribution to the East took place in 1873, and that the distribution of 1876 which was rendered possible owing to the energy of Mr. Wickham was not the first, yet to all intents and purposes the 1876 distribution is to be considered the first." The memoranda sent by Colonel Prain are as follows: "Kew Inwards book, 1873, p. 54:—'From India Office, obtained by Markham from Jas. Collins. Seeds of Hevea, India-rubber tree. Several hundred, about a dozen germinated.' This entry is in Sir Joseph Hooker's writing. The note on the germination of the seeds is in Sir W. T. Thiselton-Dyer's writing. Outwards book 1873, p. 267:—'Six plants were taken out on Sept. 22nd in a Wardian case by Dr. King for Calcutta.'"—*Ceylon Observer*, March, 1909.—[But Dr. Sir George King made little or nothing of the 6 plants he got in [illegible] —*J. F.*]

* By the *Ceylon Observer* of March 15th, I see that Mr. Carruthers, Director of Agriculture Malay States, has stated that 60,000 acres were planted there with rubber last year, and that the total planted now is 240,000 acres,

with some diffidence, as it is very difficult to know what additions Sumatra, Java, North Borneo, as well as Southern India and Burma, may make to the exports of the two chief planting countries, and also whether the price (now 5s.) will keep as high as 3s. 6d. per lb., three years hence. Be it noted, however, that the Ceylon and Malay States planters are prepared to face much lower prices; for their product can be turned out for 1s. a lb—indeed, Company reports have shown a cost so low as 9½d. In a financial paper a few days ago, it was wrongly stated that plantation rubber could not be grown at less than 1s. 6d. per lb., whereas wild rubber, costing 1s. 8d., could be supplied for less if the necessity arose. This remains to be seen; for another authority declares it costs 2s. 6d. a lb. to bring Amazonian rubber to port of shipment. The scare about "synthetic rubber" seems to have subsided, and most people accept the view of a high chemical authority that a commercial rubber is not likely to be produced in the laboratory to compete in quality or price with natural rubber. You may judge from the figures I have given, how immensely important the rubber-growing industry in all Southern Asia, covering perhaps 520,000 acres, now is, and what its value will be when all the trees are ready for tapping five or six years hence. At a moderate computation, a crop of some 36,000 tons seems then (say in 1914) to be very likely, and even at about half the present average in London, per lb., or say 2s. 6d., this means a value of £10,000,000 sterling in a single year. The share of this appertaining to Ceylon should not be less than £3,000,000 sterling, five years hence. Here is surely a reason for the Colonial Office sanctioning all the railway and road extensions pressing for attention at this time.*

37,000,000 rubber trees, or an average of 154 per acre. If so, Ceylon has been outstripped; for I scarcely think the total of planted rubber in the latter can exceed 210,000 acres at the middle of this year. But these increases should not affect the calculation as to the position in 1912. For the first quarter of this year, the exports of rubber from Malaya nd Ceylon are much in excess of the same period last ar. Mr. Carruthers also mentions that the Malay States ave now 112,000 acres planted with coconuts.

Since the Paper was read I have had the benefit of Mr. Carruthers' perusal of it, and apart from some minor corrections embodied in the text, he tells me that he considers the soil for rubber trees better in Ceylon than in Malaya, but that the climate of the latter is much more favourable for rapid growth. As regards exports, Mr. Carruthers' official return of crop for 1908 for Malay States was 1,580 tons (including Johore), and for 1912, he estimates as much as 16,000 tons—not counting Straits Settlements, Johore, Kelankan and Keda. At this rate, all Southern Asia should give 20,000 to 22,000 tons in 1912!

Camphor Trees.

Camphor is a minor product started in the higher districts of late years, and there may be trees planted now to an equivalent of 1,000 acres in the case of Ceylon.

Total Cultivation and Areas in Ceylon.

Finally, here is my estimate as compiled for "Ferguson's Ceylon Handbook and Directory" for 1908-9† of the total cultivation in the island and probable extensions:—

	Acres cultivated.		Probable eventual extension. acres.
Rice (paddy) cultivation....	610,000	..	800,000
Other grain (Kurakkan, Indian corn, pulses, and legumes)	120,000	..	250,000
Coconuts (European and Native)	750,000	..	1,000,000
Arecanuts, Palmyra, and Kitul palms	140,000	..	250,000

* A Remarkable Dividend.—An interesting annual report—that of the Korossa Rubber Co., Limited—has just reached us from Ceylon. This company possesses twenty acres only in bearing and 26 acres of young rubber. The issued capital is £6,000, and the company pays, from the profits made since the inception of the company, 21 per cent. dividend in its second year. Surely this is a record, and should provide food for thought for investors who have doubts as to the potentialities of the industry. We know of no parallel case where twenty acres in bearing have paid such a handsome dividend on the whole of the issued capital. It is quite clear that if the mature area was capitalised at actual cost there would have been a dividend considerably higher than 100 per cent.—*India Rubber Journal*, April 5th, 1909. [I may add to the above a case that came under my notice when visiting the Malay States in September last; an individual planter in the Perak district, holding 100 acres planted with rubber trees which were all in bearing in 1907, netted an income for that year of £3,500.—J. F.]

At one time the world's record for the highest value in agricultural land was held by the celebrated vineyards in the Cantenac, Margaux, and other communities of the Bordeaux district. These values, seldom over one hundred and twenty pounds per acre, had gone long before the advent of rubber plantations; but at their best they would have paled before the three hundred pounds per acre, at which rate fairly mature rubber works out in the prices actually paid for shares in some of the Malayan companies. It is possible to frame almost any estimate of profit from a rubber plantation if the returns actually given by single trees or small plots be taken to represent actual figures. Single trees have given in a few months twelve to twenty pounds of rubber, worth over five shillings per pound, and small areas have given returns equal to more than sixty pounds sterling per acre profit in the year. The planter knows, however, that when he has to deal with more closely planted trees, and has to take the average for some years of large areas, the figures will be different, although still in his slumbers dreams born of avarice are more likely than nightmares of poverty!—Thomas North Christie in *Chambers' Journal* for August, 1907.

† Published in Colombo and at 37, Shoe-lane, E.C.

Cinnamon	45,000 ..	55,000
Cardamoms (European and Native)	9,000 ..	12,000
Other spices, nutmeg, clove, pepper, vanilla, ginger, &c.	10,000 ..	50,000
Other palms and fruit-bearing trees and shrubs, jak, breadfruit, plantains, pines, oranges, mangoes, &c. ..	250,000 ..	400,000
Garden vegetables, roots, yams, cassava, manioc, potatoes, cabbages, onions, chillies, cucumbers, &c...	120,000 ..	250,000
Tea (European and Native too)	392,000 ..	429,000
Rubber trees	180,000 ..	250,000
Chocolate plant (cacao) (European and Native) ..	35,000 ..	45,000
Cinchona	173 ..	150
Camphor	1,200 ..	10,000
Sugarcane	20,000 ..	40,000
Cotton	2,000 ..	25,000
Tobacco	25,000 ..	50,000
Citronella grass and other essential oil grasses	40,000 ..	60,000
Rhea, aloes, and other fibres	1,000 ..	50,000
Coffee (both kinds), European and Native	2,000 ..	3,000
Other new products	5,000 ..	50,000
Blue gums and introduced timber trees	10,000 ..	30,000
Cultivated grass land	15,000 ..	30,000
Patana, natural pasturage, &c.	1,000,000 ..	1,000,000
Total acres..	4,087,333	5,130,150

The estimated total extent of the colony (including lakes, lagoons, backwaters, &c.) is 15,809,280 acres. It will thus be seen that at present only about 4 millions out of the 15 of which the island is composed are cultivated, or utilised for pasture.

Staple Exports from Ceylon since 1880.

I may now sum up the export of the island's staple products for a number of years:—

	Tea.	Cacao.	Rubber.	Cardamoms.	Cinchona.	Coffee.	Cinnamon.	Coconut oil, copra and punac.	Coir, rope, yarn, and fibre.	Desiccated coconut.	Plumbago.
	lbs.	cwt.	tons.	lbs.	lbs.	cwt.	lbs.	cwt.	cwt.	lbs.	cwt.
1880	162,575	121	nil.	16,069	4,161,989	656,595	1,609,548	446,246	67,763	nil.	205,738

There is also an increasing export of coconuts in the husk, as many as 21,188,692 of nuts in 1908; and of citronella oil distilled from the grass, 1,390,602 lb., and 290,878 ounces of cinnamon oil, and of pepper 1,224 cwt. last year.

The figures for 1908 are according to the Report of the Ceylon Chamber of Commerce, published at the end of February last.

* This is Ceylon produce; and besides, 134½ tons from India and Malay States, were re-exported from Colombo.

Gems.

Having in my paper on Colombo dealt fully with the native industry in gem-digging for rubies, sapphires, topazes, amethysts, catseyes, &c., which goes back to time immemorial, I will pass it over now with the remark that there are perhaps 20,000 of the natives, more or less, engaged in the very speculative work of digging pits, and washing streams for gems. Their return on the average is a poor one, probably not equal to labourers' wages; but there is the gamble, and occasionally gems worth £2,000 and even £3,000 each have been found. Cut-glass imitations from Birmingham and the Continent of Europe are freely offered in Colombo, Galle, &c., and visitors have to beware, although they cannot but be interested and perhaps agree with Miss Jewsbury, who wrote:—

> And when engirdled figures crave,
> Heed to thy bosom's glittering store—
> I see Aladdin in his cave;
> I follow Sinbad on the shore.

Pearls.

Then there is the pearl fishery on the banks off the north-west coast for which Ceylon has so long been celebrated, and which, to the advantage of the Government and people of Ceylon, was leased for a term to a London company, four years ago, with stipulations as regards experiments in culture of the pearl

oyster, which are now in process of being carried out and are full of interest. When there is a successful fishery, and still more a series of prosperous fisheries, employment is given to a large number of natives, as boatmen, divers, and workers ashore, most of the divers coming from India and the Persian Gulf, while hundreds of native dealers with thousands of attendants come from all parts of India and the East to buy the oysters or pearls.

Plumbago.

Of far greater importance to the island and people than gems or pearls is the industry in the provinces in digging or mining plumbago—our one mineral of special commercial importance—and the preparation and packing of the same in Colombo by some thousands of women chiefly, for the great firms making crucibles in London, New York, and Germany. Ceylon plumbago is nearly all devoted to crucibles, and in a time of war, with guns, &c., to make, the demand is keen. During the South African war the price doubled from £30 to £40 to £60 and £80 a ton, and as 25,000 to 30,000 tons are shipped in a year, many of the native mineowners were greatly enriched. Only one English company is engaged in plumbago mining; some of the native mines go down 350 feet and have steam-engines for the pumps, and Government has now an expert Inspector of Mines. Among other minerals found in Ceylon thorianite has recently attracted attention, and 12 cwt. were exported last year.

Elephant-catching and Art-work Industries.

Of other native industries, mention may be made of the capture of elephants to sell to the rajas and maharajas of India, of which sometimes 100 are exported in one year. Then come Kandyan art work industries, revived and maintained under official auspices, in brass, as well as silver and gold, lacquer work, in highly-coloured mats, in baskets, in pottery, &c. In the low country also numbers of the villagers weave and plait, and "Kaltura baskets" are very popular with visitors as well as in England; and, of course, there is the considerable industry in Colombo, Jaffna, Kandy, Matara, Negombo, &c., in manufacture of jewellery, cutting of gems, tortoiseshell work, ivory, horn, &c.*

Lace.

I must not omit to mention the lace industry, which employs many Sinhalese women. The lace is pillow lace, but as the industry is entirely unorganised, only the easiest kinds, such as Torchon, are made, and that is often very poor, especially as the women can only afford to buy inferior thread. Efforts are now being made to improve the quality and design, and when this is done there should be a ready market in the countries farther East, in the Australasian colonies, and America.

Fisheries.

The Fisheries round the coast give employment to many of the Sinhalese, and much might be done to add to the food supply by stocking tanks, lakes, and rivers, as well as in conserving the game of the country. Societies formed by the colonists for both purposes are in operation, and trout have been introduced into some of the mountain streams and Newara Eliya lake with success.

Forestry.

Forestry, more especially in the conservation and thinning of existing Government forests, is an important work in Ceylon, and under its present practical head, the Department has begun for the first time to supply sleepers to the railway, cheaper and of more lasting quality than have been hitherto imported. This is apart from considerable sales of timber for building, cabinet work, &c. Ceylon used to be famous for its fine cabinet woods in calamander, tamarind, satinwood, ebony, &c., and for the carving of the last-mentioned; but there is a scarcity now, calamander trees, for instance, being nearly all extinct, but the Department is arranging for nurseries and plantations. There is a certain limited export of forest produce in dyes, drugs, &c., duly recorded in the Customs accounts.

Increase of Population.

One of the best evidences of material progress and extended prosperity in Ceylon during the period of British administration is found in the increase of its population. Estimated at less than a million in 1815, when the whole island first came under our rule, it is now over four millions. A good deal of this is owing to the immigration and settlement of Tamil coolies in the island. These must now number quite 700,000, chiefly in the planting districts, though many are in the towns. But the Sinhalese have also greatly multiplied, espe-

* Any one interested in Sinhalese Arts and Crafts should refer to Dr. Comarasamy's elaborate and profusely as well as highly illustrated "Monograph on Mediæval Sinhalese Arts and Crafts," published a few months ago. Apply to the author, Broad Campden, Gloucestershire.

cially of late years, and have doubled in numbers since 1863.

Revenue, Trade and Roads.

The development of the general revenue which is now close on 2½ million pounds sterling a year, or double what it was so recently as 1893, is another prosperous indication. But still more important is the increase in the total value of the island's trade, which now approximates to from 18 to 20 millions sterling per annum, or three times what it was after the coffee failure twenty years ago, and considerably more than twice the amount it reached in the height of coffee prosperity thirty-two years back. Roads and bridges are the most potent means of developing a young colony, and in the first thirty years of the planting enterprise much was done, as well as continuously since, so that Ceylon has now about 3,000 miles of metalled and 1,000 of gravelled roads—among the best in the world—while, when the British first arrived, there was nothing worthy of the name of "road" in the island. Nevertheless, to meet the requirements of planting, especially of the new rubber industry, and of native agricultural progress in palms and rice, new roads and bridges are required and should be steadily supplied.

Railways made and Constructing.

In 1867, the first railway from Colombo to Kandy was opened, and if Governor Sir Henry Ward had had his way, this line would have been finished many years earlier, to the great advantage of agricultural industry, as well as of the island's trade and revenue. Then followed a succession of periods of agitation on the part of the colonists to get indispensable extensions sanctioned by the Colonial Office, which has far too much delayed railway progress, so that the important Dimbula-Uva line cost ten years of battling with Downing-street, to get passed. At length, in 1896, we got a strong Governor—a worthy successor of Sir Henry Ward—who carried the boldest programme of railway additions ever undertaken during one rule. This included what is known as our "Great Northern Railway," 198 miles long, opening up the North-Central and Northern districts, and connecting the densely populated Jaffna peninsula with Colombo and the rest of the island. Sir West Ridgeway also got for us the Kelani Valley narrow-gauge line of 47½ miles, serving populous native districts and one of the most prosperous planting divisions, and another 2½-feet light line of 19 miles, to serve the Sanatorium and rich planting divisions beyond. Altogether, at the end of his term of government in 1903, Ceylon had some 562 miles of railway at a cost of £5,000,000 sterling, most of which has been paid for out of general revenue, chiefly from railway profits—all the lines being owned by Government and yielding returns to the Exchequer far in excess of any of the Indian or other colonial railways. This is our justification for urging that there should be no cessation in railway construction until every revenue station in the island is connected and served. During his short term of office, Sir Henry Blake secured a small branch line, now about to be opened, from Ragama to Negombo, 14 miles, and to the same Governor also belongs the credit of an extension line of 26 miles now under construction to Ratnapura, the capital of the province of Sabaragamua and the centre not only of native mining, gemming, and agricultural industries, but of a great tea and rubber-planting enterprise.

The Manaar and Indo-Ceylon Railway.

To our present Governor (Sir Henry MacCallum) belongs the credit of securing the sanction for the important light broad gauge extension from the Great Northern line to Manaar, some 60 miles, also advocated by his predecessor. This is an important link in the Indo-Ceylon railway which is bound to be fully realised before many years go by.* The South of India Railway is extending on the metre gauge to the end of the island Rameswaram, leaving a gap of 21 miles across "Adam's Bridge" coral reef, which has been surveyed and estimated by two independent engineers (one of whom, Mr. F. J. Waring, C.M.G., has done so much for Ceylon railways). This gap, the engineers reported, can be compassed by a viaduct on screw piles or crossed by a solid roadway between two masonry walls built on the coral, for the sum of 25 million rupees, about £1,600,000 sterling—probably for less when the railway is finished on each side. Meantime, until this reef is occupied, a steam launch ferry, worked

* The project of an Indo-Ceylon railway was brought before the London Chamber of Commerce in a Paper by Mr. J. Ferguson in March, 1897, and this Paper, revised and extended, was again read before the Imperial Institute early in 1898, when a full discussion took place.

on either side of "Adam's coral bridge," according to the monsoon, can be utilised. This line will at once become the great coolie route between India and Ceylon, and also for many Europeans and well-to-do Indians, Colombo, with its magnificent harbour, becoming more and more the passenger port for Southern India, while the sanitarium of Newera Eliya, greatly improved by Sir West Ridgeway and Sir Henry MacCallum, will draw more and more visitors from all parts of India, as well as from Burma, the Straits, Australia, and Europe. Already "Cook" is arranging for through railway tickets between Calcutta (or Bombay and Madras) and Colombo.

Two Railway Extensions Urgently Required: to Chilaw-Puttalam and to Badulla and Passera.

Recurring to the subject of island railways, the urgent necessity at present is for the sanction of two more extensions to serve important towns and districts having an assured profitable traffic. First, there is the line which has been pressingly urged by the new Ceylonese body, the Low-country Products Association of Ceylon, and which would run through what is without exception the richest and one of the most populous native districts in the island, namely, from Negombo to Maravilla and Chilaw, through a continuous series of villages surrounded by rich coconut and cinnamon gardens; and thence on to Puttalam, another centre of coconut cultivation and the great source of our salt supply—a Government monopoly—ensuring a traffic of 10,000 tons of salt for distribution all over the island. This light broad gauge and cheap railway of about 54 miles is assured of traffic which, it is estimated, will yield 10 per cent. on the capital outlay, whereas the Government only require 4½ per cent. for interest, and sinking fund; and yet the Secretary of State recently proposed that a sum of two million rupees of the colony's money should be invested as a reserve outside the island, to yield 2½ or 3 per cent. interest, as a guarantee against future misfortune; and this at a time when, apart from the prosperous tea, cacao, and palm (coconut) industries, quite two to three million pounds sterling have been invested by colonists and their friends in the rich and most promising young rubber planting industry, from which the return in income, trade, and revenue is only just beginning to come in. In the planting (including palm) industry, there is a guarantee of the very best kind for Lord Crewe and his advisers, and if the two million of rupees are invested in carrying on the Negombo Railway to Chilaw (to be continued to Puttalam) they will get not 3 but 8 to 10 per cent. return on the cost, and satisfy a most loyal and industrious native population, who are extremely eager to have this railway. For the Sinhalese (Buddhists as most of them are, and, therefore, opposed to animal traffic) are the most liberal patrons of railway travelling of any population in the world, taking their means into consideration. The Legislative Council, the Planters' Association, and the Chamber of Commerce of Ceylon, as well as the Native Low-country Association have unanimously protested against this absolutely unnecessary and short-sighted locking-up of two millions of rupees, and it is to be hoped the Colonial Office will withdraw its reserve proposal and sanction an investment in the Chilaw-Puttalam Railway instead. All local railway authorities are agreed that it will be a great economy if the engineering staff and labour force construct, without interruption, the line from Negombo to Puttalam. Another most desirable and urgent section of extension is from Bandarawalla to Badulla (the capital of the province of Uva) and Passera, both centres of most important tea, cacao, and rubber cultivation, with much of native industries. This is a more difficult line from an engineering point of view; but it is certain to be profitable, and its urgency is shown by the prevalence of rinderpest among the cart bullocks in this distant province at the present time. Relief by motor-car services is projected, but such cannot be permanently satisfactory, for every year has shown increasingly the force of Sir Guilford Molesworth's declaration many years ago that for the Ceylon hill country, where the plantations mostly are, nothing can give permanent satisfaction between a good road and a good railway. Moreover, extensions to Badulla-Passera and from Negombo to Puttalam (about 100 miles in all) would meet the urgent needs of the colony for some time, and even when paid for, the total outstanding public debt of Ceylon would not exceed the equivalent of three years of the general revenue, while there would then be 760 miles of Government railway, ensuring the rapid development of agricultural industries besides yielding an ample direct return to the general revenue.

Colombo Harbour Works: Largest Artificial Harbour in the World: American Fleet Easily Taken in.

Moreover, as representing part of the Public debt and indicating material progress of a most important kind, I now come to the grand series of harbour works at Colombo,* giving us the finest and largest artificial harbour in the tropics—I may say in the British Empire; for it is only a few acres behind the National Harbour at Dover in size. There is an area of 660 acres, with a low water depth of 30 to 37 feet on much of the area, enclosed within its series of three breakwaters (1½ mile in length in all) and the harbour is supplemented by a first-class Graving Dock and Patent Slip—all due to the genius of the late Sir John Coode and his successor, Sir William Matthews, K.C.M.G.†

Thirty Thousand Passengers Annually Pass Through Colombo.

No small part of the prosperity of the Colony is due to these harbour works, which have constituted its capital (Colombo) the fourth or fifth greatest port for tonnage in the world, and which, apart from ensuring moderate regular freight for the island's produce, yield a profit to the revenue after providing interest and sinking fund on the portion of their cost raised by loan. It is estimated that 30,000 passengers (apart from natives) pass through Colombo—the marine Clapham Junction of the East—every year, and they, of course, spend much money ashore to the benefit of the Government railways, native servants, cab-owners, rickshaws, shops, hotels, &c.

Sanitation of Colombo.

And this brings me to a great work, pressing on the present Governor of Ceylon and his advisers, in the scientific drainage and sanitation of Colombo, the former being in the hands of Mr. Mansergh, of Westminster, and the latter involving great changes in Colombo Lake, which, however, I trust, will not interfere with its beauty and the amenities of its surroundings: the "blue lake of Colombo" (as Miss Martineau once put it), "whether gleaming in the sunrise or darkening in the storms of the monsoon, never loses its charm. The mountain range in the distance is an object for the eye to rest lovingly upon, whether clearly outlined against the glowing sky or dressed in soft clouds, from which Adam's Peak alone stands aloft, like a dark island in the waters above the firmament."

Other Works: Marconi System.

Sir Henry MacCallum is also duplicating part of the railway lines leading out of Colombo, a work necessitated by the great increase of passenger (native) as well as goods traffic, and he has interested himself in several other important improvements—not the least being a great telephone extension and the introduction of the Marconi system of wireless telegraphy between Minicoy and Colombo—all well calculated to promote the material progress of the colony. In other respects, it is to be hoped the Governor and his advisers, with the sanction of Lord Crewe, will do their best for the welfare of the people entrusted to their care, as well as for the liberalising of the Legislature and the Administration. But I must not enter on this to-day or go beyond the scope of my present paper, which has to do

* The foundation stone of the first breakwater was laid by H.M. The King, when as H.R.H. Prince of Wales he visited the island in December, 1875. The total cost of three breakwaters, protecting arm, graving dock, reclamations and accessories will approximate to £2,750,000 (a protecting breakwater, now under construction, will be finished before the middle of 1912). The Admiralty pays a portion (£160,000) of the Graving Dock, the first sod of which was cut by Governor Sir West Ridgeway in March, 1899. The total of the Harbour revenue now approximates to £150,000 a year and is steadily increasing year by year. Between 600,000 and 700,000 tons of coal are landed in Colombo every year, for the coaling of steamers almost entirely. There are nearly 700 licensed cargo boats in Colombo harbour. The tonnage of shipping (apart from coasting vessels) arriving at Colombo is between 7 and 8 millions, and Ceylon produce gives more than 400,000 shipping tons of freight to Europe each year.

† On the visit of the American Fleet to Colombo last December the Master Attendant of the Port was able to allot berths to all inside the harbour without interfering with the ordinary trade of the port. On the 13th December 15 large American battleships were securely berthed in the harbour in 4½ hours, and on Thursday, 17th, at noon, there were in the Harbour 41 vessels, all ocean-going steamers, including the American Fleet of 16 battleships and 4 auxiliaries. On the 20th the fleet left the harbour, consisting of 16 battleships and 2 auxiliaries, in 1 hour 13 minutes. In addition to the foregoing, which showed remarkable smartness on the part of Captain Legge and his staff, and also spoke well for the capacity of the harbour, the American despatch vessel attached to the fleet was docked, cleaned, painted and undocked in the graving dock in 24 hours, and, in fact, was the first American vessel to use the dock. The American ships are very much of the same design and capacity as H.M.'s ships, and considering that, in addition to the accommodation of the fleet and the collier auxiliaries in connection therewith, the ordinary business of the port was carried on at same time, this demonstrates that Colombo Harbour possesses great capabilities. The two main breakwaters—the south-west and north-west—are exposed to a very heavy wave stroke coming dead on from the Indian Ocean.

only with the industries and material improvement of Ceylon.*

Colonists: Brother and Sister for the Tropics.

I may mention that large as is our planting community in Ceylon—some 1,800 managers and assistants for some 1,700 regular plantations—when the rubber area now planted begins to yield widely, say by 1912, there ought to be room for additional young men to supervise the harvesting and preparation of the latex; and I may be pardoned for airing here a hobby of mine, ventilated from time to time, for many years back, when I happen to be lecturing in the United Kingdom, and on which I recently wrote in the *Spectator*, and that is that where there are daughters in a family, with a son going to the tropics (or even to any colony) a sister should accompany, or be prepared to join each brother. In the case of young men going out to be trained as planters (or as junior mercantile assistants) it would be prudent to wait till a charge was obtained or a bungalow established; but in the case of members (even cadets) of the Public Service, the salary allowed—in India especially at once, and after language examinations in the tropical colonies—is ample for setting up house, and the presence of a lady would really be an economy. I have known very many cases where valuable young lives would, humanly speaking, have been saved (over and over again, in India, and even in Ceylon) had sister accompanied brother. Then in the process of time, of course, the natural result would be an exchange of sisters (as the responsibility of married life could be faced) with this great advantage, that experience of climate and housekeeping, &c., would have been gained; while if there was failure of health through a tropical climate not suiting, it would be so much easier for a sister (than for a wife) to return home.*

Climate.

As regards climate and health in Ceylon, I can only say that during the past four months in England, I have thought more about the weather, and taken greater precautions in regard to climate, than I have done in over forty years in Ceylon—and this reminds me again of the saying of a former Chief Justice of the island, Sir Edward Creasy, in a note to his "History of England," namely, that he saw more distress (from cold, no doubt, as well as poverty) during a winter's morning walk from his lodgings in London, than during his thirteen years' residence in Ceylon.

---

* If it were within the scope of my paper, I could have here referred to the wide spread of education in the island (and the great advance of Christianity, through Missions), Ceylon being ten times in advance of India in proportion to population. But a very great deal remains to be done, more especially in female education (and in India, too, where only half a million girls are in the schools against 5,000,000 boys). As more in keeping with a paper dealing with material prosperity, mention may be made of the multiplication of substantial public offices, and especially of hospitals and schools, throughout the island: of many fine public, mercantile, and residential buildings in Colombo, including the finest hotels in the East, with good hotels also in Kandy, Newera Eliya, and other towns; and as an evidence of prosperity and enterprise, I would point to the several first-class engineering, iron, and building firms established in Colombo, and up country, ready to contract for factories and machinery for the planter, merchant, or native capitalist, or to build for Government, or private parties, to any design. It is keenly felt in the colony, that the Ceylon Government and Downing street, with the Crown Agents, do not, in this respect, give due encouragement to private enterprise, or take proper advantage of the public spirit and competition of merchants and contractors to relieve official agencies, which cannot do certain work, or supply certain materials, so economically, *pro bono publico*.

* In this connection I cannot resist quoting from a letter kindly sent me by Dr. Parkin, C.M.G., to whom I wrote on reading in one of his public addresses how much he favoured such emigration as I have indicated :—

"26th March, 1909.—I thank you sincerely for your letter of the 24th instant. and the cuttings which you enclose. With all that you say, and with all that is mentioned in the different articles, I fully agree. A few years ago, I had to make a serious study of conditions in the North West of Canada for *The Times* in a series of articles which were afterwards published, in a small book called 'The Great Dominion,' by Macmillan. The result of my studies convinced me, and I mentioned the point particularly in one of my letters, that young men were continually going to pieces when sent out alone under influences of loneliness and temptations to drink [also in the case of India and the tropics, temptation to overwork in studying for examinations, as well as in public duties, and to be careless about changing wet clothes, &c., —J. F.] and that their sisters could do no greater good than by accompanying them, and giving the country also the advantage of the influence of good English women. What was true of Canada is, as you say, still more true of tropical climates. I had much talk with the new Bishop of Zanzibar last spring on this question, when we went together to address the boys at Eton. He was full of the subject. I am quite aware that the conditions of life in such countries are in some ways harder for women to bear than for men, but hosts of women have come through it successfully, and while such countries take a heavy toll of our young men, I do not see why this toll should be made heavier through the fear of women to face the same difficulties and dangers. Both are greatly lessened when they are faced by men and women together. If I get some other opportunity, I shall try to emphasise this matter more in public. As a matter of fact, however, work of such various kinds presses upon one that it is almost impossible to find time for helping forward such ideas as this in the way that one would like to. Be sure, however, that you have my complete sympathy, and what you say will stimulate me to seize any occasion that offers for spreading the ideas."

[After the reading of the paper, some sixty slides were shown on the screen, illustrating the various towns, ancient capitals, railways—completed, constructing, and projected—the industries and products of Ceylon.]

DISCUSSION.

Mr. F. J. WARING, M.Inst.C.E., C.M.G., after showing a series of lantern views illustrating railway construction in Ceylon, said the author had given some most valuable statistics with regard to the staple exports of the island. Taking the figures for 1908 and presuming that a coconut weighed 1 lb., which was much below the mark, 1½ to 1¾ lbs. being, he thought, nearer the average, the weight of the coconut products shipped from Ceylon amounted to nearly 125,000 tons, and the net weight of the tea, not counting the packing, to 80,400 tons, most astounding figures. The author had stated that "Adam's Bridge" was largely a coral reef. As an engineer, he (Mr. Waring) wished it was. He made a complete survey of Adam's Bridge, in 1895, taking soundings between each island, in addition to making many borings to a depth of twenty-five to thirty feet, and he found nothing but sand. Adam's Bridge was about twenty-one miles across, and about half the distance was either sand-banks, or water less than three feet deep. The wider the channels between the sand-banks, as a rule, the shallower they were, but in some places where the channels were narrow, he found, by sounding, that the depth was as much as 30 feet in one case. It was a curious thing that, whether the channel was shallow or deep, a sand-bank was invariably thrown up like a bar at its mouth, so that no boats, except the smallest canoes, could pass through. On referring to a chart which was made by Lieutenants Powell and Ethersey, of the Indian Navy, between 1838 and 1845, he found that the changes in the sand-banks and the channels were so great, that the map he (Mr. Waring) made of the channels and the islands differed entirely from it, so that it might be taken for granted that the whole of Adam's Bridge consisted merely of shifting sand-banks.

Sir ARUNDEL T. ARUNDEL, K.C.S.I., said the author had referred to the ancient invasion of Ceylon. It was well known that there was an invasion by the hero and demi god, King Rama, to recover his wife, and that he went by way of Adam's Bridge, which it was said was made of monkeys, *i.e.*, the aboriginal tribes, who probably provided him with boats. He desired to ask Mr. Ferguson whether there were any legends in Ceylon which indicated that such an invasion took place, and whether the object at which they aimed was the chief city of Anuradapura. That such an invasion would have taken place for so insufficient a reason as the recovery of the wife of the demi-god Rama might be considered extremely unlikely; but it must be remembered that there was another story of a similar nature told by Homer with regard to Helen, who was abducted, and as the result the city of Troy was besieged for ten years. It might be asserted that it was romancing in both cases, and that Homer was pulling our then uncreated legs. With regard to Adam's Bridge, when he was in charge of the railway portfolio in India he visited, at the end of 1904, the island of Rameswaram. The railway was then completed as far as the last projecting point in India, but had not crossed over to the island of Rameswaram. There was then a scheme for making a port which was to be known as Port Ampthill; that the railway should be continued to the extreme end of Rameswaram; and that it should then be constructed over Adam's Bridge. In the map of Ceylon shown by the author he noticed that the projected railway up to Adam's Bridge was marked by a dotted line as a scheme. The railway had now been completed from the Indian side to the extreme end of the island of Rameswaram. As the present channel is extremely tortuous and large ships cannot go through it, it was proposed that a channel should be cut clean through the island of Rameswaram, which, as far as could be judged, was composed of sand. The suggested new channel would be about three-quarters of a mile long, and as broad as might be necessary. The question then arose whether there was proper protection for the shipping in Port Ampthill. It so happened that he met Captain Sinclair, who was in charge of the Marine Survey, and that gentleman pointed out to him that on the south side there was very little difficulty in providing for large ships, only a small portion of rock or sand having to be cleared away for the purpose. But in the end, the scheme for the construction of Port Ampthill was abandoned for the present, owing to the nature of the channel through Palk's Straight into the Bay of Bengal, which would have to be buoyed throughout. Whether that great scheme would ever be carried out in the future he did not know. The author had incidentally referred to Colonial Office obstruction. He (the speaker) did not know whether officials in Ceylon had had to complain of the action of the Home Government with regard to purchasing the stores for the harbour, &c. For instance, were they obliged to send an indent in August for a pump that they required some time in the next year? That was the sort of experience Indian officials had had, and the delays thereby caused were very serious. At one time it would have been impossible for anybody, from the Viceroy downwards, unless it was a case of extreme urgency, to order even a typewriter in Calcutta: the official had to indent for it the August of the year before he wanted it. That state of affairs had, he hoped, been considerably modified by the new rules. The author had referred to his particular hobby that brothers who went out to Ceylon should take their sisters with

them for company, marriage very often resulting with somebody else's brother. He remembered a gentleman who lived a very solitary life in India for a very long time, who finally decided to enter upon matrimony. He had been for so long in the country that he had lost touch with most of his friends in England, but he knew one family with two sisters, Mary and Elizabeth. He, therefore, addressed a letter in the most honourable way to the parents, and applied for the hand of Miss Mary, but in his postscript he said, "If Miss Mary is engaged, Miss Elizabeth will do."

Mr. G. B. LEECHMAN referred to the fascination that Ceylon exercises over all residents and visitors. Mr. Ferguson had mentioned that many believed it was the Ophir of King Solomon; others contended that it was the scene of some of the adventures of Sinbad the Sailor. One of the chief features of Sinbad's island was the Loadstone Mountain, which attracted any ship made with iron nails, &c., that came within its reach, so that it was inevitably wrecked. It was an interesting fact that the native boats in Ceylon, the catamarans, the outriggers, &c., were made entirely of wood, being lashed together with string made from the husk of the coconut. The people of the country, whether Tamil or Sinhalese, were most interesting.

Mr. JAMES PIERIS (of Colombo) said there was no one more capable of dealing with the statistics of Ceylon and the general condition of the country than Mr. Ferguson, whose residence of forty-seven years in the island had enabled him to accumulate a store of knowledge which had been of infinite use to others. He had not kept that knowledge to himself, but had freely given it not only to the people of Ceylon but to those of other countries who felt an interest in the colony, and in that way he had advanced its interests to a great degree. He (Mr. Pieris) wished to express the thanks of the people of Ceylon to Mr. Ferguson for the very good work he had done in the Legislative Council as member for the general European community. He had not represented the European community alone, but had looked after the interests of all communities.

The CHAIRMAN, in proposing a vote of thanks to the author, said all would agree that Mr. Ferguson was not only a master of his subject, but a lover of it. Indeed, as had been remarked by another speaker, that was peculiar to everybody who had been in Ceylon. No one who had lived there could help loving the island, and looking back to it with the most kindly memories. The paper had recalled to his mind very many pleasant memories, and touched several sympathetic chords. Most of those present were aware that Ceylon was a very beautiful country, with a perennial summer, situated in a region beyond cyclones and earthquakes, with a happy and contented population, a thriving revenue, and two splendid harbours in Colombo and Trincomalee, the latter, unfortunately, deserted for the moment. He desired to remind the audience of a fact which was often forgotten in connection with the Crown Colonies, namely, that in them were to be found those great harbours, which had been constructed, and were now maintained at the expense of the Crown Colonies, without which the Navy would be useless and British commerce paralysed in time of war. The disaster which befell the coffee industry, and the magnificent efforts which were made by the Ceylon planters, in the face of that disaster, were well-known. Instead of lying stricken on the ground, they rose and girded themselves, and from the ashes of that disaster there rose the still more splendid industry of tea. If any had supposed that a similar disaster might possibly befall the tea industry, the author must have convinced them that there was no such danger. In the first place, the tea plant was a very much more hardy one, and since the days of the coffee disaster science had advanced with great strides. There was now at Peradeniya a scientific staff, whose business it was to look after all the products of the island. As soon as there was any appearance of disease or pest the fact was signalled to Peradeniya, the danger cone was hoisted, instructions were issued and faithfully obeyed by the planters, and inevitably the pest was extirpated. Then, probably, a good many were not prepared to hear how little Ceylon was dependent upon tea. Many people had the idea that Ceylon had all its eggs in one basket, so that if anything happened to the tea industry the island would be ruined. That idea was really behind the hesitation of the Colonial Office to give Ceylon what it wanted in the way of railways. It was now known, from what the author had stated, that Ceylon had many industries and many products. The coconut industry, for instance, was approaching within measurable distance of tea, while the new rubber industry was exceedingly promising. He claimed for himself some credit with regard to the latter, because when he was Governor of Ceylon the rubber industry was in its infancy and somewhat ridiculed, but he added to the staff of the Peradeniya Gardens, and one of the gentlemen appointed happened to be Mr. Herbert Wright, who had been referred to in the paper. The experimental cultivation which was then undertaken supplied the seed which had enabled rubber cultivation to spread to a great extent in Ceylon. He entirely agreed with what the author had said with regard to railway construction. Railways had made Ceylon. They had made traffic, and that was the truth which had to be inculcated into those in authority at the Colonial Office. He specially wished to see the connection constructed between India and Ceylon. That was one of the ideas he had in his mind when he urged the construction of the Great Northern Railway. He had been somewhat disappointed to find that the lands which it traversed had not been opened up and occupied as he

had desired. When the railway was being constructed large irrigation works were simultaneously made, and it was his hope that when the railway was finished and the irrigation works completed, as they now were, the redundant population of the Jaffna Peninsula and South India would pour into the lands of potential fertility. Some experiments in cotton cultivation were begun, but he had not heard what the end of them was. He still hoped that the work might be entered upon, so that inducements might be offered to emigrants, and the country be able to provide itself with the rice it now had to import. Nobody admired the Colonial Office administration more than he did; justice was not done to it. It was extraordinary how the department administered the colonies in their various stages of civilisation, and with so many different races and peoples, and how sympathetically it governed. There were colonies governed absolutely by the man on the spot, and arising gradually to the stage of self-governing colonies with all the glory of practical independence. Each colony had to be treated separately, and that was where the Colonial Office had shown so much tact and wisdom. But he thought they made one mistake in trying to do everything for themselves in the Crown Colonies. Private enterprise ought to be more encouraged, and permission given for railways, now constructed out of revenue, to be made by private companies, as had been the case in India. He hoped the Colonial Office would be induced to reconsider their decision with regard to locking up Rs. 2,000,000 outside the island against possible disaster. What good would Rs. 2,000,000 do? It was a mediæval financial policy; it was the system of finance which was known and very popular with their grandmothers in their dotage, and he hoped the author and his friends would do their best to induce the Colonial Office to abandon so unenlightened a policy.

Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., in seconding the motion, said his personal thanks were due to the author for having recalled to his mind so many delightful recollections of a too short official visit to Ceylon. It had also been of great interest to him to hear of the developments of the country during the last fifteen years, in all of which, whether the extension of the railways, the initiation of a scheme for restoring old irrigation works, the conservation of forests, or the promotion of the growth of rubber, he could trace the hand of the Chairman.

The resolution was carried unanimously.

Mr. Ferguson, in reply, expressed his grateful thanks to the audience for their kind vote of thanks. Among the many omissions from the reading of his paper, perhaps the most important was the reference to the Manaar Railway, which their present "Engineer-Governor" of Ceylon had carried as a consequence of the Great Northern line being made by Sir West Ridgeway. That railway was to be constructed to the furthest point of Ceylon, and the South of India Railway Company were constructing it on the other side through the island of Ramiseram, so that only the twenty-one miles of viaduct over Adam's Bridge remained to be built. But before that viaduct was made, they hoped to have a steam-launch ferry on each side of the reef or sand-banks. He was very glad to receive Mr. Waring's correction with regard to Adam's Bridge, but there was an Anglo-Indian engineer who took a rather different view. In any case, when the viaduct came to be constructed everyone would learn what Adam's Bridge was actually made of. Sir Arundel Arundel's and Mr. Leechman's references to the old tales with regard to King Rama, &c., brought up interesting traditions; in fact, Ceylon was full of tales of romance and much of historical interest. The Seeta-ella stream in the hill regions witnessed to the capture and rescue of Queen Seeta from the Ceylon king of the demons. In conclusion, he wished to express, not only on his own behalf, but he felt sure on behalf of all the audience, their most cordial thanks to the Chairman for his great kindness in coming to preside over the meeting.

HOME INDUSTRIES.

The Wheat Industry.—The rise in the price of wheat is a matter of great national importance, apart from the seriousness of the loaf at 7d. to the mass of the community. It is of this importance because there are grounds for the belief that whilst the price of wheat is not likely to remain at 50s. a quarter—assuming it gets there—or even at its present price of 45s., the normal price will before very long be over 40s. per quarter. The late Mr. Clare Sewell Read—than whom there was no higher authority on wheat growing—told a Royal Commission some thirty years ago that it did not properly pay the English farmer to grow wheat for less than 42s. per quarter, and this opinion was never traversed by competent authority. But we must go back to 1883 to find wheat at over 40s. a quarter, and then it was only 41s. 9d. The consequence has been continuous shrinkage in the acreage under wheat. In 1875 the wheat acreage was 3,514,088; in 1885 it had fallen to 2,553,092; and in 1895, when the price had dropped to 23s. 1d. per imperial quarter, the acreage was only 1,339,806. With some recovery in price the acreage rose again in 1905 to 1,704,281 acres, but the improvement was not maintained, and in 1908 the acreage had again shrunk to 1,548,732 acres, the total production of wheat in the United Kingdom in that year being only 6,566,892 quarters, of an estimated value of £10,370,000, which means that the country has to import some 27,000,000 quarters to meet its requirements for the season ended July next. If instead of the low and unremunerative prices for wheat ruling in recent years the average stood again at over 40s.,

with likelihood of permanency at the higher rate, we should soon see an immense expansion of wheat cultivation in the United Kingdom, to the great benefit of the country. It is true that the loaf would be a little dearer than it has been during the last twenty years, but the disappearance of excessive cheapness would be much more than balanced by the check that would be given to migration to the towns. Competent opinion favours the view that we are not likely to see a return to the low prices of the nineties, and that it is not at all unlikely that the normal price of wheat will soon reach the figures given above, namely, 40s. per quarter, or over. For the supply of wheat is not likely to increase as rapidly as the demand for it. There is still a good deal of virgin soil available and suitable for wheat growing, but the wheat eating population of the world is very much larger than it was. To go no farther abroad than Germany, a generation ago the Germans were a rye-bread eating people, but now over 30 per cent. of the grain consumed is wheat. And whilst improvement in the material condition of people is leading to larger consumption of wheat, the United States, which hitherto have been the great exporters of wheat, will soon have little or none to export owing to the rapidly-growing requirements of their home market.

The Present Position.—It is commonly assumed that the wheat "corner," as it is called, in the United States is responsible for the recent rise in the price of wheat, namely, from 35s. to 45s. per quarter; but, although that has something to do with it, Mr. Patten and his associates represent only one, and the least important, of the factors to which the rise is due. Wheat is dear, and may become dearer because, whilst Europe will require during the next four months, that is, from now until the end of the season, some 20,000,000 quarters, it is not likely that the shipments will exceed 15,000,000. Assuming these figures to be approximately correct, there will be a shortage of about 5,000,000 quarters. This is taking normal requirements, but they will be reduced by economy in consumption due to high prices and the substitution of rye on the continent. When due allowance is made for these factors there will still remain a considerable shortage, which can only be made good by drawing upon stocks already greatly reduced. Taking the four years 1903-6, the normal consumption of wheat was estimated at about 405,000,000 quarters, and the world's production at about 411,000,000. Thus about 24,000,000 quarters were added to the world's stocks; but last year the world's production was put at about 382,000,000 quarters only, which greatly depleted the reserves, whilst this season's crop is put at 403,000,000 quarters with requirements amounting to 415,000,000 quarters or more. The Indian crop, which was expected to reach 40,000,000 quarters is not likely to exceed 35,000,000, the Argentine exports estimated at 13,500,000 quarters are not likely to exceed 11,500,000, of which 7,500,000 have already been shipped, and the American and Russian exports will not be up to expectations. These facts and figures go far to account not only for the present high wheat quotations but for the fear that prices may go higher, although probably it will be found that the available supplies are larger than at the moment they are assumed to be.

Naval Armaments and Trade.—It is an ill wind that blows nobody any good. Whilst social reformers are lamenting that increased expenditure upon armaments must delay indefinitely many of the measures intended to raise the economic condition of the people, one result of the expenditure must be the stimulus it will give to the iron, steel, engineering, copper, and coal trades, a stimulus that will not be confined to those trades, but will extend to other trades, until the whole industry of the country is affected by it. And what is true of this country will be true in lesser degree of the other leading countries of the world. It is estimated that for the next ten years we shall be spending something like twenty millions per annum upon the construction of Dreadnoughts and the subsidiary vessels necessary to an effective battle fleet, and not only Germany, but France, Russia, Italy, the United States, Japan, and even Austria and Spain, will be spending large sums in the reconstruction and augmentation of their fleets. This necessity for building new navies may be expected to result in quickening activity in every branch of trade.

The Present Unemployment.—The Board of Trade statistics of unemployment for March point to a slight improvement as compared with February, but it is very trifling—8·2 per cent. as compared with 8·4 per cent. In March of last year the percentage of the unemployed was only 6·4 per cent. But it would be a mistake to assume that last month's percentage as given above is a true index of labour conditions generally. The cotton, building, engineering, and shipbuilding trades account for a large section of the people regarding whom returns are made—the net membership of the 416 unions making returns was 700,654—and they were all suffering from very exceptional depression. As Mr. Beveridge points out in "Unemployment," an unemployed percentage of two for a year in a union of 10,000 might conceivably mean that 200 particular men were out of work and the other 9,800 in work the whole time or it might conceivably mean that every man of the 10,000 lost about one week in the year. Depression of trade is marked by very varying maxima. In the best years all the principal industrial groups alike tend to have about 2 per cent. unemployed. During the last twelve years the lowest figures recorded in the building trade were 0·8, in May, 1897; in the engineering trade 1·9, in January, 1897; in shipbuilding 1·4 in July, 1899. It is commonly supposed that unemployment is increasing, but the

weight of evidence is against this view. The exceptional distress of the present year may be parallelled in all essential particulars by the events of 1893-4, 1886, 1878-9, 1867, and earlier periods when the population was not much more than half what it is at present. The record of 10·7 per cent. for 1879 has never since been approached. If labour generally was becoming a drug in the market the return to labour would be diminishing; in fact, it is increasing. Taking the period 1878-1907 it will be found that there was substantial rise in rates of money wages in all the leading groups—including coal-mining, engineering, textile, agriculture—and concurrently there has been decrease in the cost of living. Official estimates put the decrease in the cost of living at 17 per cent. as between the five years from 1878 to 1882 and those from 1898 to 1902, and this has meant, of course, a corresponding rise in the value of every pound earned. Allowing for this change of values, according to Mr. Bowley's figures ("National Progress in Wealth and Trade," p. 33), the average real wages, as percentages of the level of 1900, were, in 1850, 50; in 1880, 70; in 1895, 93. Moreover, there has been a transference of labour from the lower paid to the more highly paid occupations. The present unemployment is sad, and great, but, contrasted with that of earlier years, it is by no means as great as the popular conception of it.

Farmers and Shops.—Shropshire farmers have decided to make a counter-move to the boycott by the National Meat Trades' Association of cattle offered for sale without a warranty. They intend to open competitive shops in the towns. The farmers of Newport and the district are already federated in a co-operative trading association, and it is thought to be feasible to add the retail sale of meat to the other activities of the Association. There is to be a conference of the Farmers' Associations in the adjoining counties to discuss the best means of carrying out the scheme.

CORRESPONDENCE.

DEW-PONDS.

I note in the *Journal* of the 9th inst. a further communication from Mr. George Hubbard on the above subject. I do not think a test on an insignificant scale, such as would seem to be implied by his letter, would be at all satisfactory or conclusive, and I am not personally inclined to find money on such an experimental operation.

I should welcome, as no doubt would Mr. Hubbard, the investigation of the subject by a small committee of some agricultural or other society, to be followed by a test installation. In another department of engineering practice, I am aware of a parallel case in which the necessary funds were obtained from a technical society interested in the point at issue.

It seems to me that some landowner who actually requires a water supply might opportunely join hands with an agricultural society for an installation such as I suggest, in the hope that scientific research might have a practical issue in the supply of water required on his estate.

Should my suggestion prove to be practicable, I should be quite prepared to take my due proportion of the financial risk. Should the landowner obtain his required supply of water, he would, I presume, be willing to pay a reasonable sum for the provision of the supply.

A. E. CAREY.

36, Victoria-street, S.W.,
15th April, 1909.

OBITUARY.

CÆSAR CZARNIKOW.—Mr. Cæsar Czarnikow, the well-known sugar broker, died suddenly at his residence in Eaton-square on the 17th inst. Although in the seventy-third year of his age, he had been engaged in business at his office until six o'clock on the evening preceding his decease, and his death, therefore, came as a great shock to his many friends in the City, and elsewhere. Mr. Czarnikow was a native of Sondershausen, in Germany, but he came to London when a young man, and after spending some time with a firm of brokers, he established a Colonial broker's business on his own account, which has grown under his able guidance into one of the largest of its kind in the world, having branches in New York, Glasgow, and Liverpool. Coffee and general goods were dealt in by the firm, but sugar was the product with which it was specially concerned, and Mr. Czarnikow was generally recognised as one of our principal authorities on all the difficult and thorny questions connected with the supply and consumption of this article. Mr. Czarnikow had been a Member of the Royal Society of Arts since 1901.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for

publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

DENE HOLES.—Can any further notes be contributed towards the elucidation of the mystery of our dene holes?—JOHN RYLE.

PRACTICAL APPLICATIONS OF HYDROGEN.—I was asked the other day what were the practical applications of hydrogen? I could think of none but the filling of balloons and the oxy-hydrogen light and blow-pipe. Are there any other industrial uses of the gas?—AERO.

FIRE WALKING.—I have just seen Mr. W. Coldstream's "Answer" in the *Journal* of April 2nd, and I am sure that many readers would feel as grateful as myself if he would kindly supply some of the "abundant testimony to the fact" of fire-walking in India, as well as Polynesia, of which he speaks. The whole subject is most curious, and, so far as I know, has never been scientifically investigated; but I am in hopes that we may yet receive some light on the subject when the *Journals* containing correspondence on this subject have had time to circulate among members in India and the South Seas.—MAORI.

SNAKE-STONES.—I should be glad of any information relating to snake-stones. What are they made of? And is their alleged effect on snake bites capable of any scientific explanation?—CEYLON.

EARTHENWARE FOR CLOTHING PURPOSES.—I am interested in the various uses to which ceramic products are put in the arts, and have been told that an Indian race used earthenware for clothing purposes. Having been unable to find a reference in the works on the subject, may I appeal to the members of the Royal Society of Arts, through our "Questions and Answers" column, which has already elicited so much useful information?—CERAMOS.

ANSWER.

VELLUM.—"Librarian" will find that benzine applied with a sponge will remove most stains from vellum without doing any injury to the texture.—H. LUCY.

GERMAN WHITAKER.—I know of no foreign work of reference that can be compared in excellence with Whitaker's Almanack. The best annual publication of this kind in Germany is probably Kurschner's Jahrbuch. It is published in Berlin, and the price is 1 mark. The book may be obtained through any foreign bookseller in London.—C.

NOTES ON BOOKS.

THE BOOK OF TRADE SECRETS. By an Expert. London: J. Haslam and Co., Ltd. 1s. net.

The intention of the author in compiling this little volume of recipes and instructions is to supply the collector of old MSS., books, and prints with information which will enable him to preserve his specimens and restore them to the best possible condition. Thus, *e.g.*, he gives instructions for the best means of preserving or restoring leather bindings, recipes for gum for labels, for destroying bookworms, &c. The title is explained by the statement that many of these recipes are "invaluable trade secrets," and the instructions include the most up-to-date methods practised by expert restorers. The various heads are arranged in alphabetical order, and reference is thereby made as easy as possible.

THE FERTILISATION OF TEA. By George A. Cowie, M.A. B.Sc. London: "Tropical Life" Publishing Department, John Bale, Sons, and Danielsson, Limited. 2s. 6d.

This book deals with the question of the cultivation of tea on modern and scientific lines. After an opening chapter on the tea-plant and tea-planting generally, the questions of pruning, soil, and the plant-foods necessary to secure good crops are carefully considered. "Green manuring" is discussed, and is followed by a chapter on artificial and chemical manures, and another on the best, *i.e.*, the most effective, and at the same time the safest and most economical, methods of applying this useful adjunct to the daily meal of the tea-plant, which is drawn from the soil to such an extent that no planter can afford to pass over the matter of replenishing the rapidly exhausted supplies as quickly as they are absorbed by the plant and removed by the leaves that form the crop. Unlike cacao, a tea-crop returns nothing to the soil; what is picked is lost for ever, and must be replaced. Two chapters towards the end of the book treat of the many experiments that have been made to enable the author and his fellow experts to ascertain the very best means of obtaining as large and as regular an output of tea as possible. Each method of fertilisation is brought forward and discussed; the various experiments to ascertain their respective merits are then explained, and finally the book winds up with a chapter on fertilising mixtures that should enable every planter, no matter how obstinate his soil may prove to be in responding to his efforts to increase his crop, to find at least one mixture that will bring about the desired result.

THE CEYLON HANDBOOK AND DIRECTORY.—Colombo: A. M. and J. Ferguson; London: Maclaren and Sons. 20s.

This annual volume, which has obtained a well deserved reputation in Ceylon as a compendium of useful information, is compiled and edited by the

staff of the *Ceylon Observer*, under the direction of Mr. J. Ferguson, C.M.G. It now contains over 1,500 closely-printed pages, which include, in addition to numerous directories and particulars about the public service, trade, public institutions, estates, &c., a statistical summaiy for the colony and a review of the planting industry up to July, 1908. Perhaps the most interesting feature in this connection is the rapid development of rubber cultivation. In March, 1898, it was estimated that the number of acres planted with rubber was 750; in 1904 this had risen to 11,000; in July, 1906, it had leapt up to 103,766; while the latest available returns place it at about 180,000. The acreage under tea is estimated at 392,000, and the exports of tea for 1908 at about 180,000,000 lbs. Great care has been taken to ensure the accuracy of the details given, which deal with an enormous variety of subjects, and the book should prove invaluable to all in search of statistical and reliable information concerning the island of Ceylon.

GENERAL NOTES.

Lectures on Weaving.—A course of six lectures on the "History and Technique of Weaving, with special reference to design," will be delivered by Mr. Luther Hooper at the London County Council Central School of Arts and Crafts, Southampton-row, W.C., on Friday evenings, April 23rd and 30th, and May 7th, 14th, 21st and 28th, at 8 p.m. The lectures will be fully illustrated with lantern slides and specimens, and will be free to students and others interested in weaving and design.

Association Litteraire et Artistique Internationale.—The forthcoming Congress of the Association Littéraire et Artistique will be held at the University of Copenhagen from June 21st to 26th. It will be organised under the patronage of H.M. the King of Denmark and the Danish Government. Among the principal subjects to be discussed are the report of the results of the Berlin Conference; the annual review of legislation relating to literary and artistic property; the unification of the duration of copyright; the literary and artistic rights in phonographs and cinematographs; the protection of architectural works, and the moral rights of authors. Persons desiring to attend the Congress should apply to M. A. Taillefer, General Secretary of the Association, 215 bis, Boulevard Saint Germain, Paris.

An Unemployed Census.—An interesting experiment has just been made in Manchester where an unemployed census has been made. This census demonstrates that nearly 19,000 men and women are out of regular employment in Manchester, and of these less than a quarter are earning anything by casual or partial employment. When account is taken of dependents the total number of persons affected cannot be much less than 50,000. Or to put it in another way, one person out of every twelve persons in Manchester is suffering from poverty due to loss of work. About 1,400 are disabled by disease. The immediate effect of these disclosures has been to lead the Distress Committee to rescind the resolution to close the relief works, and to make an application to the Local Government Board for a further grant to carry these works on past the 31st March, the end of the financial year.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

April 28.—"The Resources of the Peruvian Andes and Amazon." By C. Reginald Enock, F.R.G.S. Sir Clements Robert Markham, K.C.B., D.Sc., F.R.S., will preside.

May 5.—"English Furniture Design and Construction." By Percy A. Wells. Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

May 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By Professor Arthur Dendy, D.Sc., F.R.S., F.L.S.

May 19.—"Railway Development in China." By Arthur John Barry, M.Inst.C.E.

May 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By Sam Eyde.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 29.—"The Problem of Indian Labour Supply." By Selwyn Howe Fremantle, I.C.S. The Right Hon. Viscount Midleton, late Secretary of State for India, will preside.

May 13.—"Some Phases of Hinduism." By Krishna Gobinda Gupta (Member of the Council of India). Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

May 27.—"The Function of Schools of Art in India." By Cecil L. Burns, Principal of the Bombay School of Art. Professor Sir Hubert von Herkomer, C.V.O., D.C.L., R.A., will preside.

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

May 18.—"Canada as a Field for British Investment." By J. Obed Smith, Assistant Superintendent of Emigration, Department of the Interior, Canada.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

F. W. Lanchester, "Aerial Flight." Three Lectures.

Lecture I.—April 26.—*The principles of dynamic support*—The action of an inclined plane—The law of pressure reaction as a function of velocity—The law of pressure as a function of angle—Frictionless flight—The law of power expenditure as based on the laws of the pressure reaction—The laws of pressure reaction and power expenditure quantitatively considered: a discrepancy—The dipping front edge and its lesson—Cyclic motion in its relation to the supporting reaction—Direct evidences of cyclic motion—The quantitative treatment on the hypothesis of a cyclic component—The power expenditure under real conditions—Skin friction, its nature and magnitude—Skin friction as affecting power expenditure—Skin friction and other factors as limiting the wing area—Aeroplane *versus* pterygoid form—Meaning and influence of *aspect*—Importance of aspect ratio—The gliding angle, as measure of resistance—The minimum gliding angle as a function of the velocity of flight—The coefficient of skin-friction and the aspect ratio as affecting the value of the minimum gliding angle—The angle of inclination as related to the minimum gliding angle—The pressure proper to least resistance—The theory of screw propeller efficiency—Comparison of theoretical results with measurements of birds, flying machines, &c.—Controversy as to influence of skin-friction—Conclusions as affecting the problem of mechanical flight.

Lecture II.—May 3.—*The principles of stability*—The simple glider—The ballasted aeroplane—Form of the flight path as observed—The flight path as plotted from the equation—The phugoid chart and its teaching—Changes of amplitude of the phugoid curve and influences that lead to such changes—Conditions of flight path, stability and the equation of stability—Effects of propulsion on stability—Influence of the flexibility of the aerofoil—Lateral stability—Rotative stability—The stability of birds and of flying machines in practice—Flight path stability desirable but not essential to flight—Steering in altitude and azimuth—Gyroscopic couples—The boomerang—The gyroscope as an aid to stability.

Lecture III.—May 10.—*The Flying Machine.*—The function and uses of the flying machine—Possible types—The conditions to be fulfilled as defining the type—The need for high velocity—The difficulties of high velocity—The horse-power problem—Motors for flying machines and the conditions governing their weight—Fuels available and the relative importance of fuel economy—Propulsion and the propeller—The use of gearing—The limitations of flight as due to the mode of propulsion—Other modes of propulsion—Wing flapping and its efficiency—Soaring—Starting and alighting—Questions of design and construction—Steering and steering mechanism—Flying at a height—The advantages and disadvantages of altitude—Types of flying machine in practice—The future of flight—The flying machine as a mode of locomotion, in peace and war.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 26... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. W. Lanchester, "Aerial Flight." (Lecture I.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. E. H. Blake, "Some Notes on Warming and Ventilation."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. ("James Forrest" Lecture.) Colonel H. C. L. Holden, "Road Motors."

Tuesday, April 27... Royal Institution, Albemarle-street, W., 3 p.m. Prof. F. W. Mott, "The Brain in Relation to Right-Handedness and Speech." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Annual General Meeting.

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. W. R. Baldwin-Wiseman, "The Increase in the National Consumption of Water."

Photographic, 66, Russell-square, W.C., 8 p.m.

Faraday Society, 92, Victoria-street, S.W., 8 p.m. 1. Drs. F. G. Donnan and J. T. Barker, and Mr. B. P. Hill, "Experiments on the Current and Energy-Efficiencies of the Finlay Alkali Chlorine Cell." 2. Dr. Charles J. J. Fox, "The Coefficients of Absorption of Nitrogen and Oxygen in Distilled Water and Sea Water, and of Atmospheric Carbonic Acid in Sea Water." 3. Dr. Percy E. Spielmann, "The Electromotive Force of certain Platinum Compounds, with Special Reference to the Oxy-Hydrogen Gas Cell."

Wednesday, April 28... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. C. Reginald Enock, "The Resources of the Peruvian Andes and Amazon."

Geological, Burlington-house, W., 8 p.m.

Japan Society, 20, Hanover-square, W., 8½ p.m. Mr. J. A. Lee, "Some Notes on Japanese Heraldry."

United Service Institution, Whitehall, S.W., 3 p.m. Mr. J. H. Anderson, "The Spanish Succession War in Spain, with special reference to the British Action."

Thursday, April 29... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Selwyn Howe Fremantle, "The Problem of Indian Labour Supply."

Royal, Burlington-house, W., 4½ pm.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. Paterson, "Aspects of Applied Aesthetics. (Lecture II.) Landscape, Old and New."

Friday, April 30... Royal Institution, Albemarle-street, W., 9 p.m. Mr. E. Gosse, "The Pitfalls of Biography."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. C. W. Smith, "Bruges—and the Neighbourhood."

Saturday, May 1... Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. T. Günther, "The Earth Movements of the Italian Coast and their Effects. (Lecture II.) 5 p.m., Annual Meeting

Journal of the Royal Society of Arts.

No. 2,945. VOL. LVII.

FRIDAY, APRIL 30, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 3, 8 p.m. (Cantor Lecture.) F. W. LANCHESTER, "Aerial Flight." (Lecture II.)

WEDNESDAY, MAY 5, 8 p.m. (Ordinary Meeting.) PERCY A. WELLS, "English Furniture Design and Construction."

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, April 26th, Mr. F. W. LANCHESTER delivered the first lecture of his course on "Aerial Flight."

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

On Thursday afternoon, April 29th, Mr. SELWYN HOWE FREMANTLE, I.C.S., read a paper on "The Problem of Indian Labour Supply." The RT. HON. VISCOUNT MIDLETON, late Secretary of State for India, presided.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURES ON CLOCKMAKING.

The Cantor Lectures on "The Theory and Practice of Clockmaking," by SIR HENRY HARDINGE CUNYNGHAME, K.C.B., have been reprinted from the *Journal*, and the pamphlet (price two shillings) can be obtained on application to the Secretary, Royal Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures, which have been published separately, and are still on sale, can be obtained on application.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, April 20; SIR GODFREY YEATMAN LAGDEN, K.C.M.G., in the chair.

The CHAIRMAN said he took the chair in the unavoidable and regrettable absence of Lord Brassey, and his first and pleasant duty was to introduce the reader of the paper. Mr. Murray, he said, was an old friend of his who had gained experience in several continents, having served in various capacities in the public service. Mr. Murray started his career in British New Guinea as Private Secretary to the Governor, and was afterwards made Resident Magistrate. During the South African war he had the good fortune of being transferred to the Transvaal, where, at the time the great work of rebuilding the fabric of Government was going on, great scope was afforded to his energy and ability. In the Transvaal Mr. Murray served in various capacities, one being as Native Commissioner, and in performing the functions of that office he had charge of a large population of natives, and had very responsible duties of a magisterial character. Later he was called home and appointed Private Secretary to the Under-Secretary of State for the Colonies. In all those spheres he had the opportunity of gaining most valuable information, and he had always shown a keen ambition to grasp the higher side of politics. It should be the aim of Great Britain to encourage young officers of that character to study Imperial questions, and, therefore, in the name of those present he offered to Mr. Murray a very warm welcome.

The paper read was—

THE ROAD TO SOUTH AFRICAN UNION.

BY THE HON. CHARLES GIDEON MURRAY.

I consider it a high privilege to address so distinguished a Society on a subject with which so many of its members must be intimately acquainted; but it is with considerable diffidence that I venture on the task, and more so,

looking to the fact that it is a subject which bristles with controversy at every turn. I shall, however, endeavour to deal with it in such a spirit as will not, I trust, infringe the traditional usage which has uniformly marked the submission of papers for your consideration. You may, perhaps, seek the ground on which I address you on a Colonial topic, and, therefore, by way of personal introduction, I may say that for the past ten years my official life has brought me into direct contact with Colonial problems in Australasia and South Africa. My task is rendered the more difficult because certain distinguished gentlemen well versed in South African affairs, among whom I might especially mention Sir Richard Solomon and Sir Lewis Michell, have recently delivered addresses on the subject of South Africa. They, I believe myself to be correct in saying, have confined themselves chiefly to an explanation of the terms and provisions of the Draft South African Constitution Bill. So far as I am aware, however, no address has yet been delivered dealing historically with outstanding features leading up to the present situation, nor indicating the ways in which physical conditions have gradually forced the South African people to combine in despite of all the strong political factors tending to produce unrest and disunion. I propose, therefore, to give you a short account of what I may call "The Road to South African Union." In doing so, I will refer to the Customs Conferences, the railway question (a perennial source of bitterness), the Defence Conference, and some other conferences. Incidentally I will tell you of the Inter-Colonial Council of the Transvaal and Orange River Colony, and I will touch upon one or two other factors in past war history of South Africa, the presence of which should tend to establish unification on a firmer basis than could otherwise have been the case. I also propose, if time allows, to end up with a brief survey of the racial question as between Briton and Boer.

With no insurmountable physical barriers, and, therefore, for natural reasons, a country suitable for one Government, the history of South Africa since 1837—the year of the big trek and the time of the liberation of the slaves in Cape Colony—has, until recently, been one of disunion. Separate State after separate State was proclaimed—first of all in 1854 the Orange Free State; then, in 1858, a number of communities established north of the Vaal River were consolidated into one republic, the Transvaal. Natal, in the year 1856, was given a constitution. In addition to these four main States, in 1884 Basutoland was declared a Protectorate under British sovereignty. In 1895 the Bechuanaland Protectorate was formally established. In 1889 that great Empire builder, Cecil Rhodes, took possession in the name of the Chartered Company of the large territory now known as Southern Rhodesia. There is also the native territory of Swaziland, which, in consequence of the extravagance of its late ruler, Umbandini, has recently been partitioned between the natives and the whites in order to satisfy the concessions which he so recklessly gave. This territory, as in the cases of Basutoland and Bechuanaland, is administered by a Resident Commissioner, who is responsible to the High Commissioner of South Africa. Then, lastly, there is the native territory of Zululand, which was in 1897 annexed to Natal and is no longer an entity of its own, although the influence of the Zulu race upon the history of South Africa, civilised and uncivilised, can never be obscured. Here then we have, together with Cape Colony, eight different States in one country, each State working out its own destiny locally and nationally on its own distinct lines, notwithstanding the fact that in every sense collaboration and combination was and is the only rational policy.

It is by no means in recent years alone that the policy of union, as opposed to disunion, has been regarded as one to be promoted in South Africa, for as early as 1857 Sir George Grey, one of the greatest of South Africa's Governors, wrote:—"By a Federal Union alone the South African Colonies can be made so strong and so united in policy and action that they can support themselves against the native tribes." In response to his efforts, the Orange Free State Volksraad in 1858 passed a resolution favouring a plan of Federation. The Imperial Government of the day, however, refused to sanction any step which might bring in its train increased responsibilities to themselves, and thus the first movement towards union was crushed and the policy of decentralization gained stronger root.

In 1876 Lord Carnarvon, who was then Colonial Secretary, induced the Imperial Government to pass an Act enabling the various Governments in South Africa to confederate whenever they desired to do so. The movement emanated from home and not from South Africa, and, therefore, nothing came of it. May I here interpolate the observation that

movements for federation or unification, whether in South Africa, the West Indies, or any other portion of His Majesty's wide dominions, can only succeed when they spring spontaneously from the people on the spot? Lord Carnarvon's failure has taught us to walk warily in constitutional experiments of so delicate a nature.

While other factors for disunion were increasing in number, the most marked of which was the jealousy created by the growing railway competition, there appeared on the horizon one bright ray of light. Justice and expediency demanded certain concessions to the inland States in rebates of Customs duties. As a consequence, the first Customs Conference assembled in 1888 at Cape Town, between representatives of Cape Colony, the Orange Free State, and Natal. This Conference achieved nothing, but in the following year another Conference met at Bloemfontein, which resulted in the establishment of a Customs union between Cape Colony and the Orange Free State. This was gradually extended to other States, and in January, 1899, before the late Transvaal War, a Customs union had been constituted between Cape Colony, the Orange Free State, Natal, Basutoland, and the Bechuanaland Protectorate. By the terms of this Union, goods which passed through the coast colonies to the Transvaal were subject to a transit rate. The war intervened; and here let me say that it is not my intention to make allusion to that particular period of South African history beyond stating as my view that the war and its settlement have brought within nearer range the unification of the South African States. In this respect I may also mention the grant of self-government to the Transvaal and the Orange River Colony, which, by the way, has gone far to dispel Boer distrust and suspicion of British government, and will enable a South African nation to be founded upon a basis of racial compromise rather than upon racial antagonism.

In 1903, as soon as the administrative reconstruction following on the war was progressing towards completion, a Customs Union Convention assembled at Bloemfontein under the presidency of Lord Milner. As a result, the Transvaal under her new Government entered the Customs Union, from which she had previously stood aloof, and, with Southern Rhodesia also included, there appeared for the first time a union of all British South Africa for one definite object. Transit rates were abolished, and the charge for collection of duties at the coastal ports was fixed at five per cent. This Conference is especially noteworthy, in that in addition to dealing with Customs matters it passed a resolution in favour of the formation of a South African Commission to gather accurate information on affairs relating to natives and their administration and to make recommendations. The resolution began with the words:—"That in view of the coming Federation of the South African Colonies . . ." The Commission was appointed under the chairmanship of Sir Godfrey Lagden, and issued the most valuable report on native affairs and policies which has ever seen the light in South Africa. This report has been published as a Parliamentary paper, and is accessible to all who may care to study it.

In 1906, at Pietermaritzburg, another Conference met in conclave, this time under the presidency of Lord Selborne, the present High Commissioner. During the three years which had elapsed since the previous Conference South Africa had passed through a most severe period of financial depression, from which she is now slowly but surely recovering. Her people were disheartened, local jealousies had become more acute, and the lack of fresh capital was throttling industrial enterprise. The natural tendency of the various States was to fight independently for their own hands irrespective of the interests of their neighbours. The delegates, however, realised the responsibility resting on their shoulders, and, entering into the Conference in a spirit of compromise and toleration, produced a workable convention. This convention was discussed in the different Legislatures in detail, but had to be passed or rejected as a whole, for the reason that the result of rejection in part by any State would probably have meant a Customs war. The convention was accepted by all Parliaments, and South Africa, by her sacrifice of local interests on the altar of national advancement, was now one step nearer unification. I may with some advantage ask you to compare the condition of Australia in respect to her Customs with that of South Africa. Prior to Federation, each State in Australia had its separate tariff. When the States federated themselves, they proceeded to prepare a Customs convention. In South Africa, however, this has already been done. Thus the local jealousies which in the case of Australia tended, during the preparation of the tariff, to subordinate Federal to State interests, will be in the case of South Africa practically eliminated.

As I before observed, the railway question has been a chief factor in the disunion of South Africa; though, to be perfectly fair, it may be said in another sense to have had also the opposite effect, for the issues which it has raised have been so grave, and led to such acrimonious controversy, that many people, in a position to judge, have long ago formed the opinion that the only possible solution of the problem is a complete amalgamation of the railways of British South Africa. While in 1873 there were only 63½ miles of railway, in 1885, owing to the discovery and opening up of the Kimberley diamond fields, that number had been increased to 1,498 miles. In 1886 the Transvaal goldfields were discovered. In May, 1892, the Cape Colonial section of the railway, which included lines from Port Elizabeth and East London, had, by arrangement with the Free State, reached Viljoen's Drift in the Vaal River, 30 miles from Johannesburg, and by September of the same year this line had been extended to Johannesburg by the Netherlands Railway Company. Cape Colony, owing to her agreement with the Orange Free State, was, from a railway point of view, in a much stronger position than Natal, who in the meantime had not been idle, and had also linked up by rail her port of Durban with Johannesburg. In 1894 the Delagoa Bay railway to Johannesburg was completed. This route is 89 miles shorter than that from Durban, and the Transvaal owns 341 miles of that railway, as against 178 miles on the Natal route and 49 miles on the Cape route. As an independent State, the Transvaal could hardly be expected to forego any of the advantages which she derived from this command over the Delagoa Bay line, and I often notice that the anti-federationists in the Transvaal of to-day are people who have been much influenced in taking up that attitude by the fear of losing any of those advantages. Since the moment of the completion of the Delagoa Bay Railway, the whole of the railway politics of South Africa have centred round that line. The Transvaal Government commenced by fixing rates which in a very short space of time acted detrimentally upon the transit trade of Cape Colony, and, in a lesser degree, upon that of Natal. Cape Colony, however, cannot in this instance be regarded altogether as the injured innocent, for she had not disdained to take advantage of her position at the expense of the Transvaalers when she commanded the only railway line from the coast to Johannesburg. Matters reached such a pass that in 1895 a Railway Conference was held at Cape Town, at which all the States were represented. The delegates at this Conference could come to no agreement and they separated without arriving at any solution of the important matters which had caused their assemblage. The Colony thereupon proceeded to have the goods which passed over her railways ridden by transport wagons from the Vaal River to Johannesburg, and so fixed the rates as to allow her lines to compete with Durban and Delagoa Bay. The Transvaal Government retaliated by closing the Drifts, and war nearly ensued, but this was averted by the intervention of the Home Government, who prevailed upon the Transvaal to reopen the Drifts. In 1897 the Orange Free State assumed control of the lines within her territory. Under this arrangement she fared so badly, her gross receipts from that source dropping from £1,043,835 in 1896 to £738,864 in 1898, that had it not been for the outbreak of the War in 1899 she would have been forced either to resume her railway alliance with Cape Colony or to have amalgamated her railway interests with the Transvaal. In either event a war of rates would have been almost inevitable.

On the 31st October, 1902, the British military authorities handed over the railways of the Transvaal and Orange River Colony to the Common Governor in whom they were vested by Order-in-Council. Lord Milner, with the goal of Federation ever before him, recognised the baneful effect upon this object which would result by allowing the two sets of railways to revert to their former separate existence. In advocating their retention as one system he wrote to Mr. Chamberlain in a memorandum dated the 5th February, 1903:—

"It would appear that as a pure matter of business the immediate sacrifice made by the Orange River Colony in respect of its railway revenue is more than compensated for by the ultimate advantages of partnership with the Transvaal, and by giving the latter an interest in the development of railways south of the Vaal, instead of its regarding such development with indifference or even hostility. And looking at the matter from a broader point of view—the point of view of the economic development of Central South Africa as a whole and the good relations between the two colonies—the substitution of a great common interest for conflicting local interests, the impulse given to co-operation and the advancement of the Federal principle, are calculated to be of infinite value not only to the two colonies but to their neighbours."

Shortly afterwards was created the Inter-Colonial Council, which was established by Order-in-Council, dated the 20th May, 1903.

Clause 4 of the Order tells us that the Council was established to advise the High Commissioner and Governor on certain matters, the more important of which were—(1) the financial administration of the Central South African Railways (the Central South African Railways being the railways of the Transvaal and Orange River Colony) and the employment of their revenue; (2) the expenditure on the South African Constabulary; (3) any matter connected with the administration of the Central South African Railways and the South African Constabulary or any other branch of the public service common to the Transvaal and the Orange River Colony.

The Council consisted of 14 nominated members with the High Commissioner as President. Of these members ten were official, while two were elected from amongst themselves by the unofficial members of the Legislative Council of the Transvaal, and the unofficial members of the Legislative Council of the Orange River Colony elected a similar number from amongst themselves. In this manner the business interests of each colony were represented on the Inter-Colonial Council. The creation of this Council was severely criticised by the public and the Press, each journal and individual attacking it from the standpoint of the particular colony and interest represented, and this continued up to the time when the Council was dissolved in June of last year. The Council, however, kept boldly on its way, and whatever criticism can be levelled at it in regard to its sacrifice of purely local interests, its records will always demonstrate the fair-mindedness of its decisions in connection with inter-colonial railway matters. In the early days of the Council, one of its most important duties was the control of the South African Constabulary, which involved an expenditure of close upon one million sterling per annum. This was a decreasing responsibility as the years passed by, for the number of that force was constantly being reduced and the expenditure in like proportion, and I may here observe that there is nothing extraordinary in this reduction in numbers, for as the country quieted down after the war, and gradually resumed its normal state, so did the necessity decrease for a large force of mounted constabulary. On the granting of self-government the control of the force was taken out of the hands of the Council and handed over to the two colonies. His Majesty's Government so far recognised the wisdom of Lord Milner's policy in promoting the creation of the Inter-Colonial Council that, on the grant of self-government to the Transvaal, they included a clause in the Act providing for its reconstitution and maintenance; but allowing for its abrogation in the event of six months' notice being given on either side after self-government had been granted to both colonies. This was as much as could have been done by the Home Government, and the action taken by the two Governments interested in determining the Council at the end of six months is not justly to be construed as a reflection on the policy, since the ground for it was a desire to be each in full possession of its own resources with the view to the coming of union, and since, though the Council was terminated, those of its functions which related to railways continued to be vested in a Railway Board representing both colonies.

And now let us pass to South African defence, a subject which has already occupied the attention of the various States—and which acquired special prominence at the time of and since the Natal (Zulu) Rebellion of 1905. I remember so well the outbreak of this rebellion. The Duke of Connaught was visiting South Africa. At a garden party given by the Mayor of Pretoria in honour of his Royal Highness, the news was whispered round that the natives had risen in Natal. Great, naturally, was the excitement amongst the soldier guests, who scented war, while the civilians, of whom I was one, could only ponder on the horrors of it, and think of the lonely farmsteads and the women and children who might be exposed to all the inhumanities of native warfare. But to what extent were the expectations of the soldiers to be fulfilled? I will tell you—by the despatch of half a battalion of the Cameron Highlanders to Pietermaritzburg, who were kept in that town as a garrison during the remainder of the rebellion. Natal had woke up to the fact that in the train of responsible Government had come responsibility for defence, and she was determined, if possible with her own resources, to quell the disturbances which so incontinently had arisen in her midst. This, as events turned out, she was unable to do, but her resolute efforts to achieve this object, watched with admiration by the other States, aroused in them a similar spirit of emulation. They stepped in with offers of men and supplies, and between them, and without recourse to

Imperial assistance, the rebellion was finally subdued.

The spirit which produced this united action was not allowed to die, for in January, 1907, at the instigation of the Cape Government, representatives of Cape Colony, the Transvaal, Natal, the Orange River Colony, and Southern Rhodesia, met at Johannesburg, under the presidency of Lord Selborne, to discuss the question of South African Defence. It will be sufficient for the purpose of this paper if I give you the wording of the first resolution passed at this Conference:—"That this Conference is of opinion that a scheme for the combined defence of the British South African Colonies should now be arrived at which may prepare the way for the ultimate federation of the defence forces of South Africa." The Conference then proceeded to draw up a scheme which, amongst other matters, provided that the terms of enrolment for all permanently paid Volunteer and Militia Forces should be for service anywhere in South Africa, and, further, that in the event of any war or disturbance arising in South Africa the colony which became engaged should, with certain provisos, have the right to requisition the other colonies for the assistance of such forces as might be provided for by the terms of her agreements. This Conference has not yet produced any tangible results, but the time is not far distant when we may hope that its labours will bear good fruit and be embodied in a "South African Defence Bill."

I have now attempted to outline some of the most salient points in connection with the growth of a Unified South Africa. In addition to the matters with which I have already dealt, it is necessary to bear in mind that Inter-Colonial Conferences have likewise been held, firstly, to discuss the establishment of a South African Court of Appeal—which by the way has taken shape in the Draft Constitution Bill—and, secondly, for the purpose of bringing the postal affairs of the different colonies into line. Similarly the force of geographical conditions produced joint action in other matters, perhaps relatively unimportant, but still of interest, such as joint survey, joint measures for eradication of stock diseases which never cease from troubling, and also joint measures for the destruction of locusts. All these Conferences afforded opportunities for a free exchange of views between leading representatives from each colony, not only on the points strictly within the terms of reference, but on many other subordinate matters, the prior discussion of which must have been of great assistance to the delegates, many of whom had taken part in those conferences in settling the terms of the Unification Bill. So complete is it proposed that this unification should be—and may I lay particular emphasis on this point?—that all revenues from whatever source arising, over which the several colonies have at the establishment of the Union power of appropriation, are under the terms of the Bill to be vested in the Governor General-in-Council, and to be administered by the Central Government. Two funds are to be formed—a Railway and Harbour fund, into which are to be paid all revenues accruing from the administration of the railways, ports, and harbours—and these revenues will be appropriated to those purposes alone—and, secondly, a Consolidated Reserve fund, for the receipt of all other revenues. The Central Government are also to assume all debts and liabilities of the various colonies, while all stocks, cash, bankers' balances, Crown lands, public works, and securities for money belonging to each of the colonies at the establishment of the Union are to become the property of the Union.

If I may trespass upon your patience for a short time longer, I should like to add a few remarks concerning the racial question between Briton and Boer, a question which cannot but have a very important bearing upon the future success or otherwise of a unified South Africa. I do not regard this question in the same—may I say despondent—light as do many of my compatriots both in South Africa and this country. There are few people, if any, who would be so bold as to attempt to argue that in the first and even the second South African Parliament the Boers will not be in a majority. But is this an argument against unification? Sir George Farrar, Mr. Lionel Phillips, and other gentlemen of well-known British sympathies, apparently do not think so. They have stood shoulder to shoulder with their Boer neighbours, and have strained every nerve to lay the foundations of a South African nation: and if they who have made the country their home are satisfied that their work will not be in vain, surely we may hope with them that Briton and Boer will work whole-heartedly together for the common good. I came across a few sentences in a letter by their own correspondent published in the *Morning Post* of the 13th of this month which so strongly supports this view that perhaps I may be per-

mitted to give you the extract verbatim. He says:—

"Opponents of Union on the British side have not hesitated to assert that the movement for Union is a plot for the permanent establishment of Afrikander power, and Britishers who have supported the scheme as calculated to promote the better government of the Empire have been branded as the miserable dupes of the Dutch. When, however, all the world knows that the old leader of Afrikanderdom, Mr. Jan Hofmeyer, is moving heaven and earth to prevent the Union of South Africa the absurdity of such charges is at once laid bare."

In considering this racial question, I often wondered whether its solution will be found either in the fusion of the two races, or in the influx of large numbers of immigrants from other countries; and I have come to the conclusion that it will be found in both. But the one which more particularly I wish to touch on to-day is the former.

I shall always remember the occasion upon which was brought home to me the first real glimpse of the possibility of the fusion of the two races. About a year and a half after the war I was travelling on official business through a lonely part of the Northern Transvaal, and had stopped for the night at a small wayside inn. During the evening two old Boer farmers came in for some refreshment, and sat talking together—in Dutch, of course—on the general situation. They talked quite loudly, and I could not but help overhearing what they were saying. In the course of their conversation one said to the other, "Are you sending your children to the English school" (meaning the Government school)? "Yes," said the other. "But," said the first, "why are you doing that? I personally will have nothing to do with the English or their language, nor will I allow my children to." "Oh," said the second Boer, "neither will I, but my children must, otherwise they will be handicapped in life, and I wish them to make money." How this little scrap of conversation opened my eyes to the fact that if the language question were tactfully and delicately handled, this, coupled with other factors to which I will shortly refer, would go far towards bringing the two races together. The Boers are an obstinate race of strong and tenacious opinions, who, if they had found that they were being compulsorily deprived of their language—which, however unliterary, they love—would have spared no effort not only to retain that language but also to injure the nation who had dared to attempt to accomplish its destruction. Lord Selborne recognised this, and in his famous Memorandum on Education, published in 1905, he embodied the principle of the dual language. It may interest you to know that this Memorandum formed the general basis of the Education Act which was passed by the Crown Colony Government of the Transvaal, and its principles were practically re-embodied in the subsequent Act passed after the grant of responsible government. The Memorandum aroused much adverse criticism at the time on the part of the extreme British section of the population, but its justification is to be found in the fact that it has enabled British and Boer children to study side by side in the Government schools. This principle of a dual language has been carried still further, for it has been introduced into the South African Unification Bill, and I personally consider that we need regard its inclusion with no greater suspicion than we do, for instance, the language question in Canada. I had the good fortune to travel in that rich and prosperous country last year, and found there a racial question which appeared to me to exceed anything I had witnessed in South Africa. While on that tour (in Canada) I was so fortunate as to have the opportunity of discussing the two racial questions with one of the most eminent statesmen of that country. And before I go any further let me say that the comparison which I am about to draw between the racial question as it exists in South Africa and as it exists in Canada to-day is made in no spirit of disparagement to Canada, for that country has by the powerful position which she has acquired for herself not only in the British Empire but in world at large placed herself without the range of any but favourable criticism. The statesman of whom I spoke pointed out to me that, whereas in Canada the French people lived mainly in the one Province of Quebec, had their own religion (Roman Catholicism), their own language (a literary one), all their local interests in common, sat on their Parish and Town Councils together, with no admixture of the British Canadian element; on the other hand, in South Africa the Britons and Boers lived side by side in all provinces. In South Africa there were certainly as in Canada two languages, but that of the Boers was an unliterary one; their religion was the same, while in Canada it was not; and, unlike Canada, their parochial and provincial affairs were bound to be considered from the point of view of the common good

for if not they only injured their own common interests. With all these factors for fusion of the two races he asked me how there could be distrust for the future of South Africa. Many of us, I believe, will live to see a South African nation under the British flag built up, not only on the basis of national harmony, but on a foundation from which all racial discord has been eliminated, and only the elements of unity and concord remain.

DISCUSSION.

The CHAIRMAN (Sir Godfrey Lagden) thanked the reader for his extremely interesting contribution, and thought that critics would find it very difficult to fulfil their mission in regard to the paper, as there was so little in it that persons conversant with South Africa could criticise. As the reader said, the question of South African union bristled with difficulties that had been existing for a great many years. He himself was in South African territory for the best part of thirty years, and the difficulties were bristling all the time he was there; people often talked about what Sir George Grey and Lord Carnarvon had done regarding Federation, what a hopeless failure it had been, and what a hopeless failure it was always going to be. That view, he was thankful to say, had now been dispelled, and he was quite certain that people in Great Britain, as well as in South Africa, would admire the way in which the question was approached by the statesmen who conceived the idea of promoting the last conference, and by the delegates who were appointed to discuss the problem. The only way success was achieved, was by the very fine spirit of compromise with which every one of those delegates entered the conference-hall. It had to be remembered also that the whole thing was done upon the initiative of the colonies themselves, and not by any inspiration received from the Government at home. The results were a great deal more than could have been expected by most people. If all the colonists were not satisfied that they had gained or would gain all they desired by the prospective union, he was certain that all agreed that the attempt to co-ordinate the views of the different colonies had been a very able one. Personally he thought there was no doubt that, just as the Act of Union, so far as it had gone, had been unanimously accepted in principle in South Africa, so in due time a solution or solutions would be found of all those differences of detail which at the present moment were being discussed throughout South Africa and in its Parliaments. One immediate result of the steps that had been taken to unify South Africa was the almost sudden disappearance of what was called racial feeling, and racial antipathy now seemed almost a thing of the past. Another great question in South Africa that had been affected by the conference was what was called the great native question. The native in South Africa for many years past had been looked upon as a hewer of wood and a drawer of water, very little better than an animal; but the time had come when the great leaders of South African thought had recognised that it was their imperative duty to provide for development, to guide and not suppress the legitimate aspirations of the native races in South Africa. That feeling had found a voice in the counsels of statesmen of South Africa in the conference that had lately been held; it was a manifestation to the people of South Africa of the importance of the question, and a manifestation to the native that the white man was not going to grind him down, but that if he behaved himself he would be well and fairly treated. There were many difficulties in the path of union. One remarkable feature that had struck him more than anything else was the rapid way in which so many of the difficulties had been removed since the first idea of holding the conference was mooted. As Sir Lewis Michell was present, he took the opportunity of congratulating him as a delegate of the conference, and as one who had for many years done so much to promote unity, and he also congratulated those in South Africa who had promoted a conference that led to such desirable results. If he interpreted the wishes of the audience aright, he thought it would be that they wished all success in future to the task the people of South Africa had set themselves of building up a great dominion of the British Empire.

The Hon. Sir LEWIS MICHELL said a great deal of spade work had been already done in connection with the question of union. Conferences had been held for many years past, and he himself had attended no less than six in addition to the Convention from which he had just come. In 1902 he attended on behalf of Cape Colony a conference at Pretoria on the subject of a mint. All parties much desired to have a uniform coinage, but the conference split on the subject of the head of the late Queen Victoria. He for his part was not prepared to remove that venerated head from the coinage and substitute that of Paul Kruger. The conference, therefore, came to nothing. There was also a conference on Colonial Defence and another conference on Uniform Joint Stock Law, the latter making a voluminous report, which was buried somewhere. There was also a customs conference in 1898, but it was found afterwards that the decisions of the various colonies at that conference were set at nought by the fact that there was no agreement as to railway rates, and, therefore, uniform customs rates were nullified by railway rates which were not uniform. In 1903 he attended a conference at Bloemfontein under the presidency of Lord Milner, to whom South Africa was so much indebted. That agreement lasted until 1906, when a new conference met at Bloemfontein under the presidency of Lord Selborne. Another agreement was arrived at, but it did not satisfy the various colonies, and a further meeting was

held in Pretoria in 1908 when nothing at all was effected. It was, therefore, decided that at a very early date the various self-governing colonies should meet in Durban to endeavour to arrive at union. That was a great step forward. The conference met on the 12th October last year and concluded its labours on the 3rd of February this year, and did a great work in drawing up the Draft Act of Union. That Act had since been submitted to the various Parliaments in South Africa and had been passed in the Transvaal and the Orange River Colony without any amendment, passed in Natal subject to a referendum, and passed at the Cape with various not very important amendments. On the 3rd of May the Convention would meet again in Bloemfontein to see whether they could harmonise the amendments, and if they could, as he thought was possible, the Prime Ministers of the self-governing colonies would visit England and ask the Imperial Government to make the Bill an Act of Parliament. It was said in some quarters that federation would be sufficient. The conference had before them the examples of Australia and Canada, the federation of the German Empire, and of the Swiss cantons, and after considering them had preferred the type of legislative union that was created by the union of England and Scotland, or perhaps some would prefer to say by the annexation of England by Scotland. It had been said that the conference should have been content with the example of Canada. On that point he would read a very short extract from the "Life of Sir John Macdonald," the maker of the Dominion of Canada, recently written by Dr. Parkin. In 1865 Sir John Macdonald said:—"I have again and again stated in the House that if practicable I thought a legislative union would be preferable. I have always contended that if we could agree to have one Government and one Parliament legislating for the whole of these peoples it would be the best, the cheapest, the most vigorous, and the strongest system we could adopt." That was the system adopted in South Africa, and under it the union of South Africa would be one of the brightest jewels in the crown of Great Britain. The united colonies would form a compact territory possessing much good land, a hardy population, and many valuable ports, and he was thankful to say a contented and loyal population. He was quite sure that if the union went through, and Great Britain was ever in want of assistance, she would obtain it from her sons of both races in South Africa.

The Hon. Sir J. LIEGE HULETT, M.L.A. (Natal), endorsed almost everything that had been said in the paper, but thought the reader made a little mistake in dating the formation of Natal as a British colony from 1856, because prior to that Natal had two Governors, Governor West and Governor Pine. In 1856 an elected Chamber was established in Natal by Governor Scott. He himself was a colonist of over fifty years, and was interested in the development of the material resources of a portion of South Africa. The legislative union of the various colonies was perhaps the most important event in the history of South Africa. He had been in favour of the union for very many years, and as a member of the Legislature for a quarter of a century had done all he possibly could to carry forward the spirit of union. In speaking to his constituency before leaving South Africa he endeavoured to impress upon them the necessity of accepting loyally the Draft Constitution. It was a different union from that which had taken place in Canada and in Australia. It might be said in one respect not to have sprung from the people but to have been forced upon them, but in another respect it had sprung from the people's representatives. The idea of union had been in the minds of the people, but its sudden coming was a matter of great surprise. No mandate had been given to the Conference on Customs which met at Pretoria in May last. Difficulties arose in various portions on Customs, and if the conference at Pretoria had broken up without doing anything chaos would have reigned from one end of South Africa to the other. But the delegates, as statesmen, considered that they were able to go beyond the bounds of their commission, and they proposed that a conference of representatives of all the States should meet in Durban for the consideration of the question. Every State was taken by surprise, but the objections raised were quietly calming down so that at the present moment the four Parliaments of South Africa had practically passed the Draft Bill. Certain objections had been raised in Natal and Cape Colony, but it would have been impossible to frame a Constitution that had no objectionable points. At the present moment the world was looking either at the birth of a nation or the blasting of a people's hopes. South Africa could not remain in the position it was now in. It was bound to go forward to legislative union. As a very old colonist he looked forward to a bright prospect in the material prosperity of the country. He believed no other portion of the world contained greater possibilities for a large and important nation to arise. The greatest difficulty that had to be contended with was the native question. As a Natal man, and a Minister of the Crown who had had the natives of the colony under his charge, he knew the weakness of the natives and their good points. The Chairman had done a very important work in South Africa in regard to the native question. There had been rebellions in Natal, but rebellions would not be likely to occur again if the united wisdom of a united South Africa dealt with the question. Natal was chiefly the British portion of South Africa, though there was an important Dutch population, amongst whom he had many friends. He was sure the racial question would gradually be eliminated as an important factor, because he believed both races were bent upon establishing upon a right basis a commonwealth of good-will one towards the other. The racial question would be settled much more quickly in the Transvaal and in the Orange River Colony than in

the other portions of South Africa, and probably the racial difficulty would be more slowly erased from men's minds in Cape Colony than in the region where there had been war, because the fact of the frightful war of the past had caused men to think, and when men began to think they would soon begin to act. There was not the same difficulty that was experienced in Canada. In South Africa the races were intermingled; in Canada they were distinctly separated. He was a loyal Briton, but he was heartily devoted to the Garden Colony of South Africa.

Mr. P. J. H. HANNON (late of the Department of Agriculture, Cape Colony) appreciated the paper because, he thought, in this country it was necessary to spread information about South Africa a great deal more at present than had been done in the past. He had been a good many years in South Africa, and had seen something of every side of the life of the country, and could not help feeling how much the people of Great Britain had to learn with regard to South African life and conditions. Personally he felt grateful to the reader for bringing out the great indebtedness of South Africa to Lord Milner for his splendid, statesmanlike work towards South African Union. When the history of South Africa came to be written from the inside, Lord Milner and those associated with him in the *régime* which followed the war would receive their full measure of credit. Anyone who had read the speech of the Chief Justice of Cape Colony, delivered some weeks ago, would see how small were the points that had been raised against union. The necessity now was to devote energy to carrying out the great work of development which must necessarily follow the accomplishment of union itself. As had been said, only those who had been in South Africa, and face to face with the possibilities of the country could have any idea of what could be done there when all its forces were co-ordinated.

The CHAIRMAN, in proposing a vote of thanks to Mr. Murray for his extremely interesting paper, said the meeting would be pleased to learn that quite recently Mr. Murray had been selected by the Colonial Office as Administrator of St. Vincent, and he hoped it would be a stepping-stone to greater things. In bidding Mr. Murray good-bye he was sure the meeting would join with him in wishing Mr. and Mrs. Murray all success and happiness and health in their new sphere of labour.

Sir JOHN CAMERON LAMB, C.B., C.M.G., seconded the motion and expressed his pleasure at the absence of controversial matter from the paper, which gave an excellent illustration of a saying of one of the Rothschilds, that compromise was the soul of business. Mr. Murray had shown how compromise had been the soul of business in South Africa, especially in connection with the Convention. A great deal was owing to our soldiers, because the way in which the war was carried on had helped very much to prepare the people in South Africa for the union. No war was carried on with less personal rancour or ill-will on either side.

The resolution was carried unanimously.

Mr. MURRAY thanked the Chairman for his kind remarks upon the paper, which were especially valuable, because Sir Godfrey Lagden had had a wide and extensive experience in South Africa, and had taken a leading part in many of the matters with which the paper dealt. He also thanked those who had taken part in the discussion.

Sir JOHN CAMERON LAMB expressed the thanks of the audience to the Chairman for the admirable manner in which he had conducted the discussion.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 28, 1909; Sir CLEMENTS R. MARKHAM, K.C.B., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Azam, Khan Saheb Khwajah Mohammud, Dilkosha-garden, Dacca, Eastern Bengal, India.
Clarke, Percy, 13, Fleet-street, E.C.
Goolamhusein, Khan Bahadur H. M. Malak Budrudin, Medhi Bay, Nagpur, India.
Greaves, Mrs., 58, Westbourne-park-road, W.
Guy, Frederic John Vavasour, M.P.S., Kuala Lumpur, Selangor, Federated Malay States.
Habakkuk, William, M.Inst.M.M., 459, Grande Rue, Pera, Constantinople, Turkey.
Hack, Walter P. Pearson, Khartoum, Soudan, Egypt.
Matson, Ralph C., M.D., 1021, Corbett-building, Portland, Oregon, U.S.A.
Menon, T. Kunhi Krishna, B.A., M.R.A.S., Ernakulam, Cochin State, Southern India.
Nakamura, Z., President, South Manchuria Railway Company, Dairen, China.
Nonomura, Kingoro, South Manchuria Railway Company, Dairen, China.
Pet, Maung, K.S.M., Konwindat Quarter, Tavoy, Burma.
Ridsdale, Herbert Wheatley, Hill House, Burnham-on-Crouch, Essex.
Robertson, Lieut.-Colonel D. K., 8, Cadogan-mansions, Sloane-square, S.W.
Sen, Bankim Chandra, M.R.A.S., Common Room, Lincoln's-inn., W.C.
Somake, Moses J. H., McLeod-road, Karachi, India.
Volckman, George William, 197, Sparks-street, Ottawa, Canada.

The following candidates were balloted for and duly elected members of the Society:—

Conn, W. J., Railway and Civil Engineer, State Railway, British North Borneo, Papar, *viâ* Jesselton, British North Borneo.

Greenwood, H. B., The Pacific and European Telegraph Company, Necochea 183, Mendoza, Argentina, South America.

The paper read was—

THE RESOURCES OF THE PERUVIAN ANDES AND AMAZON.

By C. Reginald Enock, F.R.G.S.,
Civil and Mining Engineer.

Peru, in the popular mind, has ever been a land of El Dorado. As we behold the country from the deck of the approaching steamer, visions of Pizarro and the untold gold of the Incas crowd upon us; and raising our eyes to that far, blue maritime Cordillera of the Andes, which arises to the east, we feel some of the charm of the Great Unknown which actuated the famous Conquistadores of that memorable age of ocean chivalry which followed the discovery of America. Beyond that great natural barrier of mountains, shutting off the blue Pacific Ocean and the deserts of the coast from the interior, lay the strange empire of the Incas; soon to fall before a handful of European adventurers. This was nearly four centuries ago.

What lies beyond it to-day? There are gold mines; untold wealth of silver; there is copper and coal and quicksilver in abundance; and farther on yet there is wealth of rubber and timber and chocolate and sugar-cane, great herds of sheep and cattle and alpacas, and many other matters of satisfaction to the traveller, the capitalist, and the merchant. Upon those high plateaux, miles above the level of the sea and beyond the serrated edge of the Andes, upon which we are looking, are the beautiful old stone temples and palaces of a prehistoric race, some of which rival in massiveness and ingenuity the famous monuments of Egypt. Upon that great roof of the South American world, whose outer edge alone is visible to us from the coast, are treasures such as might enrich a whole nation, and fill fleets of plate-ships such as Drake and the kings of Spain never dreamed of. I have met weary mules staggering under the weight of ingots of solid gold and silver, as they brushed against me on the mountain trails; whilst in my own saddle-bags were plates of gold and bags of gold-dust which I had won myself from the rivers and rocks of the Andes. And far beyond the great Cordilleras we shall see canoe-loads of "black gold," the rubber from the forests, as the rubber-gatherer shoots down the rapids of the Amazon affluents towards the Iquitos market. The wealth of an empire lies within and beyond the Andes and upon the Peruvian Amazon, waiting only the set of humanity that way to gather it in for humanity's use.

To form a comprehensive idea of that great part of Western South America which forms the Republic of Peru, its geographical character must be grasped. Peru is naturally divided into three zones—the coast, the mountains, and the forest regions respectively.

First is the coast. This is a semi-arid strip of land between the Andes and the ocean, some 1,400 miles long, from Ecuador in the north to Chile in the south. The coast is beaten with a tearing surf, and, whilst there are numerous ports at which the steamers call, only three or four of them—as Callao, Chimbole, and Payta—are first-class harbours, the others being open roadsteads. This coast zone varies in width up to about 90 miles, and is traversed by small rivers at great distances apart, which descend from the Andes to the sea. Between the cultivable lands and cities, which owe their existence to these streams, great arid deserts are encountered, for the Peruvian littoral is subject to the peculiar condition of having no appreciable rainfall, due mainly to the presence of the Andes, which mountains intercept the moisture-laden winds coming from the east.

Secondly, having crossed this coast-zone, we enter among the foot-hills of the Andes and ascend the slopes of the maritime Cordillera. The Andes consist of two, and in places three, main parallel chains, the summits of which are capped with perpetual snow. Between them, at high elevations above sea-level, are great plateaux, subject to heavy rainfall; and profound river-valleys, most of which have their outlet, not to the Pacific Ocean, only a hundred or two hundred miles away, but to the Amazon, and so to the Atlantic, three thousand miles away.

Thirdly, leaving these rugged and beautiful, if inclement, regions, we descend the eastern slope of the Andes and enter the boundless river and forest system of the basin of the Upper Amazon. This is a region of which large portions are still unexplored, and of

which parts are inhabited by tribes of savage Indians, and it is generally known as the "Montaña."

These three natural zones of coast, mountains, and forest, which I have traversed on repeated occasions, are exceedingly varied in all their conditions of topography, climate, and natural resources. The means of access to these last-named regions—an important point for consideration—must be considered difficult. But it is not to be expected that a country like Peru, traversed throughout its length by a great natural barrier of mountains, with passes generally at 15,000 or 16,000 feet above sea level, could yet be equipped very fully with roads and railways. Nevertheless two railways traverse the Andes, and others are projected or under construction. Of these two railways the northernmost is the famous Oroya line, which, leaving tide-water at Callao, passes through Lima and ascends the Andes to an elevation of 15,660 feet above sea-level—the highest railway in the world—and within one day the traveller is taken from the warm climate of the coast up to the region of perpetual snow. The other Peruvian trans-Andine railway is some 500 miles to the southward of the Oroya line. Leaving the port of Mollendo, it ascends to Arequipa and Lake Titicaca, crossing the Cordillera at an elevation of 14,660 feet above sea-level, and running thence to the famous old Inca capital of Cuzco. Beyond these two important routes of travel the remaining railways of Peru are short lines from the seaports, crossing the coast-zone and terminating at the base of the Andes. There is, however, an important branch line from Oroya to Cerro de Pasco, where a large new copper-producing industry has been set going of recent years. As to roads in Peru, there are practically none except the numerous mule-tracks, which give access to the towns and villages of the interior and the mines, and which are not practicable for vehicles. In some cases, as you journey along these roads, so precipitous are they, and so remarkably do they wind among the precipices and ravines, that the town to which you are journeying is seen thousands of feet below you, a day or more before you get there. Perhaps you encounter a train of laden mules just as you are passing one of these precipitous places, and some care is necessary to avoid being crowded off the path or injured by the packages they carry, which stick out on either side of them. It does not sooth your temper to be prodded in the leg with the corner of a sheet of corrugated iron, or a baulk of timber, or a bale of merchandise! However, the dangers and discomforts of the trail are often compensated for by the grandeur of the scenery and the interest of the journey, especially in the mountain regions. Nevertheless, conditions of travel in Peru, away from the lines of railway, must be looked upon as arduous and difficult, although they do not present necessarily impossible obstacles to development.

To turn now to a description of the natural resources and products of the country, it will be advisable to describe these as pertaining to the three respective zones of coast, mountains, and forests. In general terms, agriculture and matters pertaining thereto are a greater source of wealth at present than minerals and mining, notwithstanding the great wealth of minerals awaiting exploitation. Indeed, Peru has been likened to "a beggar sitting upon a pile of gold," the meaning of which is that the country's natural wealth is vast; but capital and enterprise for its extraction are lacking.

The principal source of wealth and industry on the coast-zone is the growing of the sugar-cane and the manufacture of sugar and rum; the growing and export of cotton; and the production of wine. The Peruvian planters claim a high yield of cane and sugar per acre from the soil, greater than that of Java, Hawaii, or Louisiana; and the yield is given in Government publications as several times greater than that of any of those famous districts. The sugar estates are generally situated on the margins of the rivers crossing the coast-zone, and are irrigated by means of canals from these rivers. Among the most productive valleys are those of Chicama, Trujillo, Chimbote and Santa in the north; the Rimac valley, near Lima; Cañete and the Tambo valley, further south. A good deal of British capital is invested in the production of sugar in this zone, generally with gratifying results; and many of the sugar estates, both Peruvian and British, are large and powerful concerns. Typical of the latter may be mentioned the Santa Barbara estate of the British Sugar Company, producing some 25,000 tons of sugar annually, and involving the constant upkeep of 10,000 acres of cane. On most of the estates large quantities of rum are manufactured, much of which is exported to the interior and to Bolivia. Unfortunately the consumption of alcohol among the Peruvian and Bolivian Indians is an increasing vice, and is beginning to have a markedly injurious effect upon the native

working population of the highlands. Upon these sugar estates, Japanese labourers are now being employed. Very few negroes, however, are encountered upon the littoral of Peru, and none whatever in the highlands, owing to the cold climate of the latter regions. Indeed, it is interesting to observe how Nature preserves the highlands of the Andes for the indigenous people. The negro will not go there, and the Chinaman is not plentiful. I once ascended from the hot coast-zone to the uplands, with a Peruvian negro mule-driver, whom I had employed, and his main desire was to finish the journey quickly, and get back to his warm village on the sands!

The sugar-cane flourishes up to an elevation —above sea-level—of 4,500 feet, on the Pacific slope. It is also cultivated, to a considerable extent, in the inter-andine valleys and the Montaña, or eastern slope, and is cultivated as high as 6,000 feet elevation. The average value in recent years of the sugar export of Peru has been about one and a-half million pounds sterling. The home consumption is about 30,000 tons per annum.

Cotton cultivation is an important industry in the coast-zone, the cotton being grown under irrigation. The plantations extend from the seashore to 60 miles inland, along some of the valleys, and the principal varieties grown are the Egyptian and the native kinds. Peruvian cottons are favourably known on the British market, especially the "full rough" and the "moderate rough," which are of excellent and unique qualities. The principal cotton-growing valleys are those of Piura, Lima, Ica, and Tambo de Mora. The annual value of the cotton export is in the neighbourhood of half-a-million sterling, and it is increasing; more land is being put under cultivation, owing to higher prices. There is some British capital invested in the production of cotton.

As regards the conditions of the coast-zone generally, it may be stated that the climate is good and temperate. Indeed, it is remarkable in this respect, as will be judged from the mean temperature, which ranges from 63° Fahr. in the south to 77° Fahr. in the north. No other country in the world in similar latitudes (3° to 19° S.) offers so cool a temperature, and the traveller coming from Panama and Guayaquil upon the same coast finds unexpected relief from the extreme heat of those places. Comparison between the Pacific coast of Peru and the Atlantic coast of Brazil in the same latitude shows a remarkable difference in favour of Peru, Lima giving an average of 66° Fahr. and Bahia 77° Fahr. This condition in Peru is due to the absence of moisture, the proximity of the Andes, and the existence of the Humbolt current.

Agriculture upon this coast-zone can only be extended by means of further irrigation works, and this calls for foreign capital, and offers a remunerative field for the employment of such, especially in cotton-growing. The cities and towns of the littoral are largely dependent for their means of subsistence upon produce brought in by steamers and schooners, and the growing population calls for extended cultivation. The establishing of cold-storage and chilled meat depôts, both in Peruvian and Chilean coast towns, ought to prove a paying enterprise, according to investigations I have made, as it would tend to regulate the great fluctuations in the price of meat and other provisions, for all cattle are imported or brought down from the interior.

The principal inhabitants of the animal world on the Peruvian coast are the myriads of web-footed sea birds—the palmipeds—the producers of the famous guano deposits, which have been so prominent a feature in the recent history of Peru. No nitrate beds of any importance have been found in Peruvian territory north of Tarapacá, and, indeed, the life of the Chilean deposits is generally estimated at about 40 years, although it is possible that this is much under-estimated. The resources of the Peruvian coast-zone must always be mainly agricultural, dependent entirely upon irrigation, which latter condition is by no means unfavourable, ensuring as it does a regularity in the crops. The area of land in this zone capable of such cultivation is estimated at 50 million acres, of which only 1½ millions are cultivated at present. Under the influence of water a large porton of the appalling deserts or pampas of this zone which, in some cases are as destitute of vegetation as the Sahara, can be turned into fruitful plantations, after the manner of California.

The next region to be considered is that of the Sierra—the slopes and highlands of the mighty Andes of Peru. We have heard much recently about Tibet. Peru, indeed, has been well termed the Tibet of America, and the analogy is very marked. Great mountain ranges, divided by high, bleak plateaux, profound valleys, lakes, and swamps, all crowned by the stupendous summits and peaks of the Cordilleras, with a crest of perpetual snow —such are the Andes of Peru and Bolivia. Beautiful, solitary, rigorous, are these vast high regions, and the gleaming, culminating

snow-clad peaks, tinged with the sunrise or sunset glow and piercing the blue heavens up to 20,000 feet above sea level, never fade entirely from the recollection of the traveller who has dwelt among them, or essayed their ascent. It fell to my lot to ascend and cross several snowy peaks and passes untrodden before by human foot. However, in Peru, instead of opposition to travel, as in Tibet, according to the accounts, hospitality is encountered, at any rate, among people of Spanish descent. On somé occasions, on arriving at a remote town and presenting my introductions—or even without such—the principal citizen of the place has prepard a feast for me and invited his friends, delighted at the advent of an Englishman on a scientific errand, in a place so cut off from the happenings of the outside world, and I retain pleasant recollections of their hospitality. On the other hand, among the Cholos and the Indians of some remote regions the greatest distrust and lack of hospitality is encountered, and nothing even in the way of necessary food can be purchased. In some of my long journeys into these places, on one or two occasions I have been obliged to go without food for days, except what little remained in the saddle bags, or to take it by force, leaving double its value in the hands of its protesting owners. This, however, is rare, and, as a rule, the Cholos of the most remote places are amenable to reason, once they know they are going to be treated with fairness, and not abused; and I have always told them that an Englishman, at least, always pays for what he takes!

On long prospecting expeditions I have found it well to live as much as possible on what the country passed through afforded, carrying of course, such essentials as tea, coffee, sugar, extract of beef, &c., in the saddle-bags of my men. Indeed, a few hints for intending travellers may not be out of place here; for on any tour of discovery, or examination of mining regions, reliance has to be placed much on one's own resources, as railways are soon left far behind. Such provisions as eggs, chickens, bread, or—failing that—toasted maize, potatoes, rice and fruit, can generally be purchased at the village, and in the cold regions, a sheep can be carried along on mule-back, and pieces cut off as required. No traveller will ever venture forth into the Peruvian interior without his own saddle, which he will purchase in Lima, an English saddle being quite unsuitable. An equally important part of his impedimenta is his folding-cot and bedding. On no account go without it if you intend to leave the line of railway. No great preparations for clothing are needed—an ordinary tweed riding suit and leather leggings and shooting boots are the main essentials, with a thick woollen poncho for the uplands and mountain regions, a thin white one for the coast deserts, and an indiarubber riding-cape for the rain. I know of no greater pleasure than, properly equipped, with all your worldly belongings securely packed upon a couple of pack-mules in charge of a careful mule-driver, to start forth into those little-known regions of Western America, there to discover what Nature holds of use for science and for commerce.

The uplands of the Andes are inhabited by the hardy Cholo race, the descendants of the Quechuas and the Aymaras, who formed the population of the Peruvian empire under the Incas. They live principally by agriculture and the raising of cattle, llamas, and alpacas, and the sale of wool, and also by mining. The singular and graceful llama, or American camel, is encountered everywhere near man's habitation in these high remote regions, and it forms the most valued possession of the poor Cholo, doing all his carrying trade and furnishing him, in conjunction with the alpaca, with the valuable commodity of wool, which is readily purchased for export to Liverpool. The annual value of the wool export is rather more than half a million sterling.

The Cholos and Indians inhabiting the Andine uplands—their habitat ranges from 7,000 to 17,000 feet or more in elevation above sea level—have retained one notable condition from their Inca progenitors: they are independent land-holders. Each Cholo and his family is the owner of a small holding, which he cultivates with alfalfa, maize, potatoes, or whatever product the position affords, thus supporting himself and his family in a way which renders him practically independent of the governing white Peruvian race. The Cholo asks little from civilisation, or at any rate from the civilisation of the Europeans, who destroyed that of his former Inca rulers, which was certainly not inferior to that which governs him at present. Indeed, the main blessings of modern civilisation, if such they may be termed, in those remote regions might be described in two words—priestcraft and alcohol! What these two words convey it is beyond the province of this paper to discuss.

The land system of these people is worthy of note, or at least the land laws under which they lived in the time of the Incas are, especially to-day in view of the question of small holdings in Britain. All the land was measured up and proper areas apportioned to every inhabitant, the area being increased as his family increased. They were obliged to work the land, and beggary, poverty, or destitution was not permitted, as every inhabitant was provided for and enjoyed his birthright of a piece of land, by the working of which he could maintain his family. Taxes to the Incas were payable in goods, not money, and in goods—as clothes, arms, or other matters—such as the particular district afforded. Indeed, so beneficent does the social system under the Incas appear to have been that it has given rise to the assertion that the primitive people of the Andes enjoyed a rule under their native princes such as has never been enjoyed by any Christian nation. To-day, all over the interminable slopes and valleys of the Andes these small holdings are encountered, abandoned in the greater part, owing to the extraordinary shrinkage of the population since the advent of the Spaniards. I have stood upon the summit of the hills as the sun cast shadows over their slopes, bringing into relief, with a singular chequered appearance, the innumerable small terraces, or "andenes," as these small holdings were termed, excavated on the upper, and banked up on the lower sides, to form flat places for cultivation. Many of these are used to-day, and the inhabitants of remote villages still elect their petty land-officials, whose duty it is to assign the use of the water in turn, for irrigation of the lands, as in the time of the Incas. But the greater part of them lie untenanted and abandoned, like the innumerable ruins of villages, cities, castles, and temples which the traveller encounters throughout this vast region of the Peruvian Sierra.

It is not within the province of this short paper to enter into a description of the great monuments in stone which have been left scattered about the uplands of the Andes, extending over many thousands of miles of territory. I have dwelt upon them fully in my books upon Peru.* The Incas cut and carried great monoliths and erected buildings of cut stone of such solid beauty as excite our admiration even to-day, as we look upon their ruins; and wonderful roads and bridges. There they stand, these ruins, in marked contrast to the flimsy adobe structures for the present occupiers of the land—temples, palaces, fortresses, and strange buildings of religious and astronomical purpose, and we may stand there amid their crumbling walls, and mark, as did the votive priests of old, the sun-god of the Incas as it sinks in the Occident.

These high, bleak tablelands of the Peruvian Andes are intersected by fertile valleys, which enjoy a delicious climate in many cases, with semi-tropical fruits and produce in abundance, and in these favoured spots the towns, which form the centres of the white or mixed population (as distinguished from the Cholos and indigenous red race), have their being. Most of these towns are much isolated from the coast and the outer world, their only means of communication being the ill-formed pack-mule trails, which wind interminably over the great punas or highland planes, cross deep valleys and precipitous-sided ravines and rapid rivers, and at times traverse mountain passes across the perpetual snow fields of the Cordilleras. Nevertheless, their inhabitants live in contentment; living is cheap; the struggle for life is less acute than in the manufacturing cities of North America or Europe; and the poorer Cholo or Indian of these regions is a far less trying spectacle than the pallid and starving slum-dweller of New York or London! Foreigners may journey and live in these regions with entire security; and with a very small capital at disposal can amass wealth and property, in mines, plantations, and commerce.

To turn now to these resources of Peru which ever have formed for the foreigner, and doubtless ever will form the most alluring field of work and enterprise—the mines. This vast region of the Andes embodies in Peru a mineral-bearing zone, 1,500 miles long and up to 500 miles wide; and within it every metal and mineral known to commerce is encountered. Silver, gold, copper, lead, quicksilver, coal, iron, zinc, petroleum, vanadium, molybdenite, bismuth, sulphur, nickel, cobalt, salt, and everything else are found and worked in Peru. Yet, notwithstanding this great wealth, the mineral industry at present is small relatively, although it is increasing rapidly, having triplicated itself since 1903. The value of the mineral and metal export annually at present is about three millions sterling. The backward position of mining is due to the lack of foreign capital, added to the

* "Peru" and "The Andes and the Amazon." London: T. Fisher Unwin.

slow development of means of communication, and to the fact that Peru has not generally enjoyed a favourable credit in European commercial centres—a condition, however, which is now being to some extent overcome.

I will now describe, as far as the limits of this paper will permit, the modes of occurrence and conditions for practical working of the principal minerals. The most widely distributed of these are gold, silver, copper, and coal. Gold occurs on both the western and eastern sides of the Peruvian Andes, although as alluvial or placer deposits only on the eastern side. Indeed, Peru may be looked upon as an exceedingly important source of gold for the world's future needs. For engineering and mining purposes the occurrence of Peruvian gold may be divided into three classes; and these, in the relative order of their importance for present working, are—first, the great banks and deposits of gold-bearing gravel for hydraulicking; second, the exceedingly numerous lodes of auriferous quartz; and third, the areas of gold-bearing deposits susceptible to dredging. There is no space here to go into the matter of the geological origin of the auriferous material, except to say that the existence of alluvial gold is due to the disintegration of innumerable gold-bearing lodes and veins which traversed, and still traverse the rocks of the great Cordilleras. Geological epochs of heavy rainfall and orographic change, especially under glacial action, have, as time went on, caused the disintegration of these rocks, the gold contained having accumulated in the bottoms of the great lakes which formerly existed in the Andine plateaux and valleys. A remaining instance of these is the great lake basin of Titicaca, which even to-day forms a hydrographic entity, with no outlet for its waters except that of evaporation. In some cases these enormous deposits of auriferous earth and gravel were subsequently upheaved by orographic change, and at the present time there exists a series of such deposits along the very summit of the Peruvian and Bolivian Andes, upon the actual water-parting of the continent, at elevations above sea-level of 15,000 to 18,000 feet. It is not to be supposed that the remarkable situation of these deposits renders them unworkable. Some of them which I have visited have been worked by the Indians for centuries, and in one or two cases modern hydraulic systems of "monitors" have been installed there. In some cases, as it is natural to suppose upon the water-parting, water is scarce and the climate is rigorous at this altitude. As giving an idea of the magnitude of these deposits of auriferous earth, it may be stated that a calculation has been made of a single one that it contains more gold than has ever come out of the whole of California.

Lower down on the eastern side of the Cordillera are some huge deposits of gold-bearing gravel under more favourable conditions for working, for at lower elevations there is abundant water and timber, whilst the climate is mild, and food products of any nature may be grown—conditions not encountered on the high summits. As an instance of these great auriferous deposits may be mentioned the mines of Aporoma, which I made a special expedition to examine. This great auriferous deposit is several miles in length and width, and it has been calculated that it contains gold to the value of £40,000,000 sterling, recoverable by the ordinary hydraulic methods. These mines were partly worked by the Incas before the advent of the Spaniards, and then by the brother of Pizarro. Later on, under one of the viceroys, works were constructed which cost £500,000, consisting of canals, aqueducts, tunnels under the ridges, sluiceways, &c. At present these are much overgrown with vegetation, but the situation of the deposit, with ample water supply and good conditions for the disposal of tailings, render it exceptionally favourable for working. The average value of the gravel, which was obtained by panning portions of the almost vertical faces of the huge banks, cut down for 500 or 1,000 feet deep by ravines, is about 2s. 6d. per ton of material.

On the eastern slope of the Peruvian Andes most of the rivers and streams are rich in alluvial gold, and the natives have a system of paving river-bars with stones in some places and recovering the gold annually brought down by the freshets. These are known as "gold farms." Whether upon the streams which flow into the great Madre de Dios river in the south of Peru, or whether those of the Marañon 600 or 700 miles to the north, both of which systems I have visited, gold is recovered in considerable quantities by the Indians in the form of dust and nuggets, and used as a medium of exchange in the villages. In my examination of some of these places I found the gold to be easily recoverable. I recollect one old Indian woman who lived in a hut on the top of a great bank of gravel, full of gold, who used sometimes to ask me, in her broken Spanish and Quechua, "Has the Señor found much gold to-day?" If I replied in the nega-

tive, she said, "Never mind, I will get you some," and taking her pan, formed of a big gourd, such as the Indians use for gold-washing, she disappeared into some ravine, known to herself, and in the course of an hour or so came back to present me with gold dust, varying in weight up to half an ounce, which she had washed out. Indeed, at certain seasons of the year, the Indians—men and women—leave their planting of maize and potatoes, and go gold-washing in the streams.

The areas of land susceptible to gold recovery by means of dredging, are very much lower down towards the Amazon plain, where the rivers have lost much of their velocity, and the very fine gold has been deposited in the silt. There is no doubt that an enormous quantity of gold must exist in this form, the work of the elements for ages, and some attempts recently have been made to take in gold dredges for recovering it. But this must be looked upon as extremely hazardous at present. A dredge is a heavy and complicated piece of machinery, and when it has been conveyed from the Pacific Coast up to the Andes and carried thereover and down into the montaña on mule-back and by Indians it is likely to suffer from the lack of repairing facilities in such a region. Moreover, the streams are subject to very sudden floods due to the tropical rainfall, and the few dredges which, so far, have been taken in have suffered disaster from being carried on to the rocks by sudden floods. Perhaps the region is too inaccessible yet for the successful operation of these machines, although the engineer and explorer is loath to think so. As to "hydraulic" mining of the deposits of gold-bearing gravel, of which I have already spoken, the conditions are more favourable, and no machinery at all is required for their working; nothing but iron pipes and nozzles.

We now come to the matter of gold-quartz lodes. These are exceedingly numerous, and are found throughout the country. In order that an exact idea may be formed of the value of such mines, I will give figures of some of those which I have examined, and which may be taken to some extent as typical:—In the southern part of the country is a group of gold-quartz lodes existing under favourable conditions for working. The ten main lodes or veins cross a deep valley, ascending the slopes and traversing a plateau on both sides. The outcrop of these lodes is from 2,000 to 3,000 feet above the lowest adit level on the valley floor, and the lode extends downwards to unknown depths. The lodes are traceable and have old workings upon them for a length of twelve miles, so that the dimensions of depth and length show the existence of a vast quantity of ore. As to the widths of the lodes, they vary up to eight feet generally, enclosing strong ore-bodies of good pay ore, whose value, as shown by the yield of workings extending over some years, may be taken at two ounces per ton, 70 per cent. of which is recoverable by amalgamation on the battery plates, and the balance by the usual methods from the pyrites with which it is associated. Thus the ore lends itself to relatively cheap mining by means of adit levels, whilst facilities both for water-power and for treatment are obtainable from the river, which flows near at hand. It is evidence of the backward state of mining in Peru, that, notwithstanding that this good district is at a distance of only 50 or 60 miles from the coast, it has remained neglected. Here is an opportunity for capitalists.

Another district has strong lodes up to 10 feet wide in places, whose ore values are 1½ ounces per ton. The ore is a smelting ore, carrying a high percentage of lead, and both water-power and coal are found close at hand. Yet another group of old mines contains 12 strong lodes, whose gold values range from two to seven ounces per ton, with high grades of silver, and these have been extensively worked at the surface, for miles in length, by native miners, who have extracted the ore from the upper or oxidised portion of the lodes, and have recovered the free gold by amalgamation in their primitive appliances. In other parts of Peru I have examined gold and silver lodes which carry pay ore in great bodies up to 150 feet in width, with external old workings, and these only require modern methods and appliances to yield up their wealth again. In yet another district is an almost inexhaustible area of gold-bearing conglomerate, averaging about three-quarters of an ounce to the ton. All that has been done in such countries as Mexico can be much more than duplicated in Peru, where nature has disposed things in the Andes on a much more stupendous scale.

As to silver, the hills of Peru are, in certain regions, literally honeycombed with old working upon rich lodes; and the Andes are dotted with ancient reduction works for recovering the white metal. From one district alone—Cerro de Pasco—silver was produced, from the end of the eighteenth to the end of the nine-

teenth centuries, to the value of £40,000,000; whilst the present output is somewhat under a million pounds. The present condition of many of these valuable Peruvian silver mines is that their workings are water-logged, and the native miner's resources do not generally permit them to spend money in long adit levels or pumping machinery for drainage. I have discovered and examined numerous mines of this nature—sometimes abandoned and without owners, open to anyone who chose to lay claim to them—which contain great bodies of rich silver ore, and the cost of draining and working these would be comparatively small. Great fortunes have been made almost by the stroke of a pick in Peru in the past in these silver mines, and conditions are much the same to-day. Probably no country in the world offers such exceptional conditions for those who are desirous of risking money in mining, and the expenditure of very large capital is not necessary. Generally speaking, all the elements of rich and abundant ore, proven lodes, water power, fuel, and cheap labour are to be found, and the only requisites are capital and management.

As regards copper, Peru may be expected to prove an important source of this metal when railways are extended into the regions where it occurs. The possibilities of Peruvian copper are being shown by the Cerro de Pasco deposits, to work which the American company has spent, it is stated, some fourteen million dollars. A line of railway, 80 miles long, and smelting furnaces of large capacity have been constructed, and are in operation; and the district has been pronounced by British and American experts to be the largest copper-ore deposit in the world. There are other copper-bearing districts, only of secondary importance, more remote, however, from lines of railway; for it is a peculiarity of Peru that no copper deposits of value are found near the coast.

Coal abounds throughout Peru. I have examined numerous strong seams of anthracite standing vertically, in some cases, with exposed outcrops, and crowning the hills for miles. As a rule, these have remained unworked, owing to difficulties of transport, but they form a valuable asset for the future. In one region exist hundreds of millions of tons of coal exposed at the surface. Short lines of railway from the coast are necessary to work these deposits. There are, in addition, important deposits of coal upon the coast, which have only been discovered the past few years, both in the northern and in the southern part of the country; in some cases extending under the sea.

Space forbids me to do more than mention the existence of the deposits of quicksilver ores, and the innumerable lead, zinc and other lodes and veins. The famous quicksilver mines of Peru yielded up a great revenue in past centuries to the Crown of Spain, and were pronounced by one of the viceroys as "one of the finest jewels of the Spanish Crown." I examined these important mines and consider their possibilities are very great. They might supply the world's market almost. In the northern part of Peru, near Tumbez, the petroleum wells are of considerable value: they are worked principally by British firms and the output finds a market in the country itself.

Leaving the high regions of the Andes we descend to the third natural zone of Peru, the "Montaña," or region of the forests of the Amazon plain. The natural resources of this vast region might be summed up by saying that it forms one of the world's great natural storehouses for the future. It is traversed by navigable streams and rivers in great part; all affluents of the Amazon. Of these waters 10,000 miles are navigable at all seasons of the year for steamers of varying draught, whilst in the wet season the total available navigable waters in rivers and streams, for steamers, launches, and canoes, exceeds 20,000 miles, all in Peruvian territory.

The main product of this wild region at present is rubber, of which the output is valued at about 1¼ millions sterling per annum. In the Peruvian montaña there are very extensive rubber-bearing forests, both in that part of the Amazon plain drained by the affluents of the Madre de Dios river, and, although less known, the region to the north drained by the Marañon and Huallaga. The principal Peruvian rubber-bearing trees are the Shiringa or Hevea, and the Caucho. The Hevea is the superior kind, and is that which has made Brazil famous as a rubber-producer. The tree requires a rich, deep soil and abundant moisture, and at times grows to great size. It lends itself to cultivation, although not much has been done in Peru yet in rubber-planting. Large areas of rubber-bearing land have been taken up in Peru, principally by Peruvians but partly by foreign companies, though much land still remains unoccupied.

Chocolate, sugar, cotton, cocaine, quinine, and a great variety of tropical fruits are also

produced. The possibilities for producing chocolate are very great. This region is one of the most fertile in the world; almost anything can be produced under cultivation; and instead of being the home, principally, of roving savages and monkeys it might be the centre of a great civilisation. As to the climate this in the higher region is healthy and pleasant. In the hot valleys of the lower region malaria is encountered, and this is always the greatest scourge, before drainage and ventilation are carried out. The principal drawback to the business of rubber collecting is the lack of labour, for, as regards transport, the waterways of the Amazon system afford means of outlet to Iquitos and thence to Europe or the United States down the Amazon. That the river port of Iquitos is destined to become of great importance, cannot be doubted. It is the commercial centre for the whole of this vast north-eastern region of the Peruvian montaña, and notwithstanding that it is 2,500 miles up the river, it is reached by the Liverpool steamers of the Booth line of 3,000 tons burden. The Amazon at Iquitos is three-quarters of a mile wide. One-tenth of the whole foreign trade of Peru is done with Iquitos, the main article of export being the rubber.

This vast territory of the Peruvian montaña is one which any nation might be proud to possess, but it is time it should be opened up to civilisation, and its natural resources turned to wealth. For this purpose railways are needed, and the construction of some is projected. Among the most important projects of this nature is one to unite the headwaters of the Peruvian Amazon, or Marañon, with the Pacific coast port of Payta, upon which I have been occupied for some time. The line has remarkable characteristics and possibilities. It will be only 400 miles long, yet it will create a new transcontinental route of trade and travel between the Atlantic and the Pacific seaboards—a route of which the 3,000 miles of the Amazon, navigable for steamships, forms the natural highway. The line will cross the Andes at the low elevation of 6,600 feet above sea level—the only low gap existing in the many thousands of miles of snow-bound Cordillera, which extend throughout Ecuador, Peru, and Chile. The important geographical conditions and the possibilities of the route across South America in its widest portion have never been brought forward before, and the fact that steam navigation from Europe can be carried on upon the Amazon, to within 260 miles of the Pacific coast, is not generally grasped.

To sum up, the natural resources of Peru are varied and abundant, and in many branches of industrial activity British capital can be profitably employed. At present British commerce with Peru greatly exceeds that of any other nation, and British interests control the principal railways of the country, whilst, as before stated, there is a good deal of British capital invested in sugar and cotton production. American and German activity and enterprise are, however, growing rapidly. In mining, British enterprise is not favourably marked so far, except in the old-established and well-equipped Casapalca smelting works. Some of the other mining enterprises of British origin have not done well, but the fault has been in mismanagement rather than in the mines themselves. Indeed, in some cases, these have been established under questionable native and foreign auspices, and have suffered in consequence, such as the gold mines, near Chimbote; the Recuay copper mines, and others. However, there can be no doubt that when the present lack of mining enterprise in London passes, attention will be turned to Peru and its stores of gold, silver, copper, and coal. Capital will then be drawn to investment there.

Directly affecting the resources of a country such as Peru, is the character of its inhabitants. The Peruvians, as a whole, are a hospitable and well-meaning people, with a cultured upper class. Since the loss of their nitrate wealth, they have shown some disposition towards taking off their coats, and going to work to develop their country, and, indeed, the great territory of Peru's mountain and forest region is of far higher value than the nitrate wealth of Tarapaca, whose life can be measured now by decades. The Peruvian upper class is a Spanish-speaking white and mixed race, but fond of ease; the women are attractive and vivacious. Lima has always been a centre of Spanish-American civilisation and culture inherited from the time of the viceroys. In their business methods the Peruvians as individuals have yet a good deal to learn, their greatest failing being the lack of rigid observance of word and bond; but they are a young nation with their future before them. More workers are the country's principal need, and more ideas from the outside. The small population of 3,000,000 souls—of which 50 per cent. are Cholos and Indians—inhabiting an area of 700,000 square miles, scarcely increases, and immigration at present is nil, notwithstanding the possibilities for immigrants. Remote from Europe, Peru

is one of those countries which may be expected to benefit by the Panama Canal, whenever that great work may be completed. The political and financial conditions of the country are good at present; the budget yields a surplus, and the best governing elements of the country are controlling the affairs of State, with the result that no revolution has occurred for 14 years. Knowing Peru and her people as perhaps few Englishmen know it, it has been for me a pleasure to respond to the invitation of the Royal Society of Arts to spread some wider knowledge of a country which is worthily striving to carry out its destiny in those splendid regions of the Pacific, the Andes, and the Amazon.

DISCUSSION.

The CHAIRMAN (Sir Clements Markham), in opening the discussion, said he had seldom listened to such an immense amount of valuable and interesting information condensed within so short a space of time, and the author had shown that he was just as apt with his pen as he was in travel and exploration. He was exceedingly pleased to hear Mr. Enock's reference to the hospitality of the people of Peru. Although he had travelled in a great many countries, he had never met with such hearty hospitality as he did throughout his journeys in Peru, both on the coast and in the interior. When travelling in the Montaña, he had to cut his way through the forests for weeks together, while he found the four young Indians who accompanied him as good companions as he could ever wish to have in work of the kind. Without their skill in cutting away the dense forests he could not have travelled through the country, and they were as good in encamping and as faithful to him as any men he had ever worked with. Although those events occurred many years ago, he looked back with pleasure on the intercourse he had had both with the upper classes of Peru and with the Indians.

Mr. H. HAMEL SMITH enquired about the nature of the labour available, and whether any would have to be imported, provided it was decided to cultivate rubber in Peru. It would also be of interest if information was forthcoming as to whether the cost of the land would be an important consideration in the question, and whether the transport of the rubber when it was grown would be a serious matter. Would it be possible to bring the produce down to the Pacific coast instead of, as at present, having to make the long journey down the Amazon to the Atlantic seaboard? Unless that was possible it would render the profitable cultivation of rubber in Peru quite hopeless, compared with the Federated Malay States and Ceylon, where the cost of transport was comparatively low. He understood that the rubber grown in Peru was of excellent quality, as it was in Bolivia, but the danger and expense of cultivating it was very great.

Miss WEBSTER thought the value of the paper would be increased if the author could give some particulars of the trees found in the forests. Were there any timber trees?

Mr. J. B. CARRUTHERS asked the author for information respecting the proportion of Para rubber trees in the natural jungle region he had described as rubber-producing, and what were the possibilities of extracting the rubber from them, apart altogether from the question of planting rubber.

Mr. E. T. SCAMMELL, in dealing with the question of the mineral resources of the country, said he had been struck with amazement to hear that such richly productive gold mines were in existence, and yet they had not been developed. If the facts with regard to the possibility of obtaining a two-ounce ore and even a seven-ounce ore were circulated far and wide, something might be done to develop such a great industry, although there was no doubt that the difficulties to be encountered were very great.

Mr. ENOCK, in reply, said that labour in the forest regions was rather scarce, and he believed some of the rubber companies engaged there had found that their main difficulty. Peru was anxious to introduce Japanese labour, a good deal of which was employed on the coast. The natural outlet of the rubber region was down the Amazon, because the rubber forests existed on the tributaries of that river. It had, nevertheless, been found cheaper by some of the companies working the rubber lands to bring the rubber over the Andes and down the railway to Mollendo. As soon as roads, perhaps motor roads, and short lines of railways were constructed on the natural outlet down the Amazon, he thought there would be an enormous development of trade. The Amazon forests possessed the peculiarity that they were unlike the other forests of the world, which consisted very largely of one kind of tree. They consisted of all kinds of trees, in fact he believed it had been calculated that in one square mile there existed thousands of different kinds of trees, and this rendered the Amazon forests perhaps of less value than some of the other forests of the world. If a particular kind of tree was required, it was sometimes necessary to hunt about for it a good deal. There were, however, great groves of what was termed cedar there, although it was not a true cedar; but it was a valuable wood. Valuable hard woods also grew in the forests. The question of the proportion of rubber trees to other trees was hard to answer. The rubber-bearing land was confined to a certain zone of land upon the margin of the rivers which were tributary to the Amazon; but it was impossible to state the exact proportion it

occupied of the total area. The political conditions of the country in years gone by were mainly responsible for the fact that the gold mines in the country had not been worked. The country had not had a good name, and, as a consequence, not much prospecting work had been done. But the condition of affairs was now very much altered. There was no doubt that the mines of Peru ought to be at the present time attractive to capital, because they could be obtained under very easy conditions, and in many cases they offered relatively easy methods of working. Peru might now be said to be in the condition of Mexico ten or twenty years ago, when many of the mines, which were now yielding enormous incomes to British companies, were practically going begging. The same state of affairs now existed in Peru, and the present was the opportunity for taking the mines up.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Enock for his interesting paper, and the meeting terminated.

PERSIAN CALICO.

A considerable trade is now being carried on in Persia, especially at Ispahan, in printed calico suitable for curtains for doors and windows, for tables and couches, and for wall hangings. The larger pieces are about twenty feet long by three feet or four feet wide, others about six feet by six feet, and many other sizes. The cotton cloth for printing is manufactured at Ispahan, although the foreign product is rather preferred. The designs are often exquisite, representations of flowers, peacocks with spread tail feathers, almonds, the tree of life (with or without leaves), leopards, elephants, lions, deer, and hunting scenes, in which the men are depicted as shooting arrows at wild boars; war scenes, which are extremely grotesque—large men on disproportionately small horses cleaving one another with great swords, splitting the body in two: important events of the national history, and countless other interesting designs. The American Consul at Ispahan says that in North-East Persia these are generally called "Kalamkars," and may be secured sometimes at the price of about 4s. per square yard. While the name by which they are known signifies "pen work," a stylus is used only in tracing delicate lines after the main design has been produced by the method of block printing. The block is of hard wood, containing in relief the design which is frequently repeated on the same piece. One block scores for only one colour, accordingly many blocks must be used in completing the design. Pieces of cotton cloth are first immersed in material contained in the intestines of sheep, drying and washing follow, and then they are kept for a time in a solution of gall nuts. Afterwards they are dried in the sun. To secure black colouring fluid, old rusty nails are kept for two or three weeks in water, which is occasionally stirred; the water is drawn off, a small quantity of castor oil and alum is added, and boiled down to a pasty consistency, this is then applied to the block. For red, some bol Armenian and alum are boiled with gum of the apricot or other trees contained in small muslin bags. The designs are for the most part in black and red. To secure blue, a paste of indigo and water is boiled, and to this are added some potash, lime, and grape syrup; blue is generally applied to the cloth hot. The main ingredient for yellow is pomegranate skin boiled with alum. After the application of the colours, the cotton fabric must be washed and spread out in the sun and frequently sprinkled. The above process ensures fast colours. When aniline dyes are employed the colours are almost invariably fugitive. Factories in Russia, and to some extent elsewhere in Europe, are producing cotton prints of Persian designs, and some of these are introduced even into Persia itself.

ANTWERP AND ITS SHIPPING.

Decline of British Trade.

The consular Report on the shipping and navigation of the port of Antwerp for the year 1908 is not very encouraging reading for Britishers. The year referred to was a particularly depressing and unsuccessful one from a commercial point of view, and the shipping trade, in common with many other industries, suffered from the lack of confidence in the financial world. Antwerp, like most other ports, has been hard hit of late years, and during the close of 1907 was in the throes of a labour strike; but notwithstanding this, there is some satisfaction in the fact that the returns for 1908 show but a small decline compared with those of the previous year. The most serious part of the business, though, for us is that the navigation returns for all shipping entering Antwerp showed a falling off in 1908, and that this decline is more than accounted for by the decrease of British shipping, both in the number of vessels and the aggregate tonnage. Not only was this the case, but the shipping trade of our commercial rivals increased. The foremost of them—need it be said—was Germany. The tonnage of German vessels visiting Antwerp has increased by 100 per cent. since 1900, while if one goes still further back, *i.e.*, to 1889, the contrast between her progress and that of our own country is still more striking. In that year the tonnage entering the port of Antwerp under the British as compared with that under the German flag was as 23 to 6, while last year the figures were as 5 to 3, a rate which seems to indicate that, within a measurable distance time, the German tonnage at this important port of Northern Europe will actually rival that of the United Kingdom.

HOME INDUSTRIES.

Railway Amalgamation.—The decision of the railway companies concerned—the Great Eastern, Great Northern, and Great Central railway companies —to withdraw the Bill authorising amalgamation will have occasioned but little surprise. The conditions under which the House of Commons consented to read the Bill a second time—and this only by a small majority—and the terms of the reference to the Select Committee, made it probable that the ultimate sanction of Parliament to amalgamation could only be obtained by concessions the companies were not prepared to make. The wide terms of the reference to the Committee—"to enable the whole case for amalgamation to be examined, not only with reference to the special interests affecting this particular Bill, but in the general and national interest"—would have made the inquiry costly and prolonged beyond precedent, and the labour troubles threatened in the event of the Bill passing through Parliament, probably had something to do with the decision of the companies not to go on with it. However that may be, the withdrawal of the Bill will be welcomed by the large number of traders and travellers who view such combinations, however carefully safeguarded by Parliament, with inveterate distrust, as inevitably tending to increased charges and restricted facilities. On the other hand, it will be regretted that the scheme embodied in the Bill, which would have afforded a valuable test of the extent to which retrenchments are possible under centralised administration can be carried without prejudice to the public interests, is dropped. It is possible, however, and even probable, that the companies have some alternative scheme for non-competitive working which will not require Parliamentary sanction, and which will enable them to put into operation many of the economies intended to be effected by the rejected Bill.

Alcoholic License Taxation.—It may or may not be the intention of the Chancellor of the Exchequer to propose an increase in the duties on licenses to sell alcoholic liquors—that will be known before this Note is read—nor is this the place to discuss the merits or otherwise of any such increase, but it may be of interest to note the course of license taxation, and how slight the changes have been since the first beer license duty was imposed in 1710, in the shape of a small stamp duty of one shilling. Forty-five years later it was raised to a guinea, and in 1810 to two guineas. As late as 1880 it was only two and a half guineas, while at the present time the annual license duty of a beerhouse proper is only £3 10s. per annum, while for a combined beer and wine license it is only £4 per annum. So with the publican's spirit license, in 1800 the average cost of a license to retail spirits was £5 1s. 6d., and in 1840 it was only 6s. 3d. more. In the next forty years there was no change. Indeed, in 1880, the average cost of a retail license for spirits was only £7 18s. 8d. as against £5 1s. 6d., in 1800. It was in 1880, that Mr. Gladstone introduced the "full" license, which allows the sale of any alcoholic liquor for "on" or "off" consumption. The range of duty was then extended from a minimum of £4 10s. for public houses under £10 annual value, to a maximum of £60 for houses of or above £700 annual value, and nothing has been done since 1880 to alter the scale. In the meantime there has been considerable restriction of licenses. Between 1880 and 1907-8 the number of publicans' licenses in the United Kingdom fell from 96,727, or 2·8 per 1,000 inhabitants, to 84,493, or 2·0 per 1,000 inhabitants, a decrease of 7 per cent. On the other hand, the estimated total expenditure on alcohol during the same period has risen from £145,500,000 to £167,000,000, or nearly 15 per cent. With 7,234 fewer public houses the expenditure on drink increased £21,500,000. The inequalities of incidence, too, are very marked. The same license of £60 is paid indifferently by all public houses rated at £700 and upwards. Between 1883 and 1908 the number of houses rated at £700 and upwards in England and Wales increased by 676, or 285 per cent. There are in London no fewer than 479 licensed public houses rated at £700 and upwards. Of these 74 are residential hotels possessing ordinary public house licenses. Their rateable value ranges from £700 to £31,000, but the license duty charged is the same, namely, £60.

Scotch Tweed.—Some months ago, reference was made in these Notes to the attempt to secure an official definition for Scotch tweed, but owing to the inability of the manufacturers to come to an agreement among themselves the movement is still in the stage of discussion. The definition originally suggested and adopted by the South of Scotland Chamber of Commerce in June, 1907, was "an all-wool cloth made in Scotland from yarn spun in Scotland," but last year a committee of the Chamber amended the proposed definition, so as to read, "A pure wool cloth made in Scotland, pure wool being wool which has not formed part of any woven or knitted fabric." At a special meeting of the Chamber to consider this proposed amendment, it was resolved to adhere to the original definition, it being considered that that definition was as good a guarantee of purity, and that in the event of further precautions, it would constitute a more workable standard. It has been objected to this resolution, and the dissent has been formally recorded, that it admits of the use of all kinds of woollen waste and recovered wool fibre, while it debars cloth from being described as Scotch tweed which has been sold as such for over forty years. Here the matter rests for the present, but there seems to be a growing desire in the trade to make another effort to obtain a definition which would be generally accepted. The difficulties in the way have, however, been greatly increased by the widely varying character of the fabrics manufactured in the south of Scotland, and the knotty point whether a worsted fabric is or is not a Scotch

tweed. Cheap Yorkshire cloths have become formidable competitors of the more costly Scottish tweeds, it being almost impossible for experts to detect the difference without an analysis, so close are the imitations.

The Production of Pig Iron.—The returns made by Iron Masters to the British Iron Trade Association show that the production of pig iron in the United Kingdom last year amounted to 9,289,840 tons as compared with 9,923,856 tons in 1907, and 10,149,383 tons in 1906. The decrease of 634,016 tons is the greatest recorded in any year since 1902.

Co-partnery.—In the course of a speech, delivered at West Hartlepool a few days ago, upon the occasion of the freedom of the burgh being conferred upon him, Sir Christopher Furness dwelt upon the formidable character of the foreign rivalry with which British manufacturers and traders have now to reckon, and expressed a confident opinion that nothing will enable it to be met successfully more than a system of co-partnery with its invaluable adjunct of a Work Council. Sir Christopher Furness would like to see it brought, in some form or other, into operation in every trade into which it can be made applicable throughout the kingdom. Impressed with the necessity for it, he suggests a national conference of the leading employers of the kingdom, in the hope and belief that a careful and sympathetic examination of the principle and practice of co-partnery would result in the adoption of a resolution to give effect thereto in the fashion, of course, best suited to the circumstances of each particular industry or trade. Such a determination would, he thinks, in the course of a few years not only transform the basis, but heighten the spirit and multiply enormously the resources of British industry and trade. "If," said Sir Christopher Furness, in words that deserve to be remembered, "we wish to maintain our supremacy, if we wish to lead the lives of self-respecting Englishmen worthy of the race from which we have sprung, we must doff the garb of frivolity, and cease to view life as a piece of play. We must throw off our personal self-conceit, and our national complacency, and become earnest students of our industrial aud commercial environment. We must manifest as never before initiative, zeal, energy, care, ability, industry. The best available instrument for meeting and overcoming this crisis in our national life is the principle of co-partnership."

Wheat and Meat.—It seems as if those who are responsible for the present attempt to "corner" the wheat market in America will fail as others have failed before them, high prices bringing out unexpected reserves. Prices have fallen considerably but there is no likelihood that for some time to come they will fall below paying quotations, and this for the reasons given in these Notes last week. The hope of a return to agricultural prosperity has never been so widespread since the price of wheat fell below 40s. per quarter, and although this country is never again likely to grow half the wheat it consumes, the acreage under wheat might quite conceivably be doubled, or even trebled, to the great advantage of the community. Meantime the dispute between the farmers and butchers as to meat warranty shows no signs of settlement. The butcher asks that he shall be relieved of loss with regard to animals which he buys in good faith at a fair market price and which, though apparently healthy, prove when slaughtered to be affected with disease. Farmers object because they consider it would be unjust to relieve the butcher of all risk at their expense, and to transfer his trade risk to their shoulders. The butcher wants the warranty not only to protect them against trade loss, but to lessen the risk of prosecution by the local authority, since it would give him the opportunity of proving his *bona fides.* It is admitted that butchers have a real grievance as to the existing law and practice with regard to want of uniformity in inspection, seizure, and condemnation of meat, and the manner in which prosecutions are sometimes instituted by the local authorities. A system of mutual insurance would seem to be the way out of the difficulty. Vendor and purchaser would then share the loss, but the Agricultural Committee are not at present prepared to go beyond the suggestion that vendors of stock should contribute to local butchers' insurance funds, a proposal considered inadequate by the butchers.

CORRESPONDENCE.

THE INTELLIGENCE OF THE ELEPHANT.

The very interesting paper in the *Journal* of the 16th inst., on "The Intelligence of Elephants" induces me to relate a fact which will tend to confirm the author's statements as to the animal's "intellectual power."

About forty years ago the late George Wombwell was travelling through the West Midlands with his famous show. The procession of caravans and animals was proceeding through the streets of the little town of Tenbury, when, within a short distance of the show ground, a fine Indian elephant (recently acquired at a cost, I believe, of about £1,000) caused a great commotion by suddenly "trumpeting" in an alarming manner and in a few moments was lying prostrate in the street. "Nellie"—for this was the elephant's name—had been seized with a fit of colic. A local "Vet." was soon found, in the person of a Mr. Turly, whose administrations enabled "Nellie" ultimately to be got on her feet and taken to a neighbouring stable. Here she received the careful and kind attention of Mr. Turly, who was successful in relieving the pain, and in four days she was

all right and proceeded to join the show in another town.

Seven years later Wombwell with "Nellie" again visited Tenbury, and as the procession made its way through the crowd "Nellie" suddenly raised her trumpeting voice and, leaving the procession, walked across the street to Mr. Turly, whom she had recognised, standing on the pavement. To the consternation of the people she quickly put her trunk around him, picked him up, gave him a couple of "gentle hugs," then placing him quietly down on his feet she marched back into the procession. After seven years she had not forgotten her benefactor. This fact in my opinion is not only confirmatory of the fine memory of the elephant; it also proves the ability of its intelligence to show gratitude and affection.

WILLIAM HOULSTON MORGAN.

Blakeney, Glos.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

CAUSTIC SODA.—A workman is making chemical manure, using caustic soda. He places this with water in a copper, but finds he has taken too much caustic. He returns this diluted overplus to a bottle-necked empty can and corks it up. In three days he thinks of using this again and lays the can on its side, taking out the cork. It is of the consistency of thick, slowly moving gum, with a crust formed on the surface. Standing a yard away he gets a receptacle for it to run into, when it bursts forth from the neck of the can as by an explosion full on the face and head of the workman, needless to say with serious consequences, disfiguring him for life, for it is of so sticky a nature as to render it difficult of quick removal. Can anyone explain the cause of this?—F. J. W. PLASKITT.

EARLY PATTERN OF ELECTRIC LAMP.—As far back as December 15, 1799, Thomas Grenville wrote from Stowe to Lord Grenville, who had a seat near Slough:—"I have this moment received an explanation of the electric lamp which I enclose for the evening amusement of all at Dropmore. Its cost—including packing—is just under five louis d'or." (Hist. MSS. Comm.: "Dropmore Papers," vi. 78.) Whose experimental lamp would this be? One of Volta's?—R. B.

ANSWERS.

EARTHENWARE FOR CLOTHING PURPOSES.—"Ceramos" is correct in his recollection as to the use of earthenware as an article of clothing. There was a tribe of Brazilian Indians, living on the island of Pacoval, at the mouth of the Amazon river, whose sole covering appears to have been a piece of pottery. These curious objects are called in Portuguese "tanga," that being the name of the small apron worn by savage tribes. The tanga was a curved piece of earthenware, of triangular contour and about the size of the hand. It was suspended like an apron by means of strings, for the attachment of which holes are provided in the three corners. The convex surface is elaborately ornamented; but, curiously enough, the design is not adapted to the shape of the article, but is broken off abruptly at the lower edges of the triangle. From the nature of the designs and the breaking of the continuity at the sides it would appear that the first tangas were made from the pieces of the earthenware vessels used by the same Indians. When they were afterwards specially made as an article of clothing the broken design was retained by the potter, as savage ladies do not so readily change their fashions as their more civilised sisters. "Ceramos" will find an excellent and well-illustrated article on the subject by Professor C. F. Hartt in the "Archivós do Museu Nacional do Rio de Janeiro," 1876, p. 21; there are specimens in the museums of Rio de Janeiro and Cornell University.—WALTER F. REID.

SNAKE-STONES.—There are several varieties of snake-stones, the majority of which have virtue attributed to them for which it would be difficult to find any scientific justification. They may be classed with the mascottes in vogue even at the present day amongst ourselves. There is one variety, however, which has some scientific justification. It is black and so porous that it adheres to the tongue. It is upon this porosity that its efficacy in case of snake bite depends. Placed upon an open wound it absorbs the blood with such avidity that it is quite possible the venom might be sucked out of a snake bite in this way. This kind of stone is really animal charcoal and may be made by heating a piece of ivory or stag horn, embedded in powdered charcoal, to a dull red heat. If, after repeated use, the porosity of the material diminishes, it may be restored by heating in this way. A much better material may be made of a kieselguhr composition, and I have made and used this successfully in treating bee stings. "Ceylon

will find that two things are absolutely necessary to ensure success with these materials: they must be applied as soon as possible, and the wound must be open so that an outward flow of blood can take place, carrying the poison with it.—WALTER F. REID.

NOTES ON BOOKS.

THE ANDES AND THE AMAZONS, 21s., and PERU, 10s. 6d. By C. Reginald Enock, F.R.G.S. London: T. Fisher Unwin.

In these two books, which have now run into several editions, Mr. Enock gives a graphic and exhaustive account of one of the most interesting countries in the world. The pages are packed with information of the most varied kinds, for the author's interests appear to be very many-sided, including alike history, geography, ethnography, zoology, botany, mining and engineering; and he seems to be equally at home whether estimating the enormous mineral resources of Peru, telling the terrible story of Pizarro, or describing the amazing stone-masonry of the Incas Nor does he fail in appreciation of the picturesque. His descriptions of the scenery, aided as they are by the many excellent photographs which illustrate the volumes, convey impressions of an extraordinarily beautiful country, which is, perhaps, none the less romantic and alluring because it is so difficult of access. Mr. Enock's style, too, is well suited for a book of travels: it is simple, yet vivid, and contains just enough of the personal note to make the reader feel that he is viewing the scenes described in the author's company.

THE RAT PROBLEM. By W. R. Boelter. London: John Bale, Ltd. 1909. 2s. 6d.

The author is one of the ounders of the Society for the Destruction of Vermin, and has given much attention to the question of the damage done by rats and its prevention. The book gives a history of the rat, an account of the various ways in which it injures health and property, an estimate of the pecuniary loss it inflicts on this country alone (stated as £15,000,000 per annum), and a description of the various methods proposed for its destruction. It advocates the passing of a law authorising the official extermination of the animal and providing means to this end.

PRACTICAL ORGANIC CHEMISTRY.—By J. J. Sudborough, Ph.D., D.Sc., F.I.C., and T. Campbell James, M.A., B.Sc. London: Blackie and Son. 5s. net.

This work differs from most laboratory text-books on organic chemistry in the large number of experiments which it describes. It deals not merely with the preparation of typical organic compounds, but includes typical preparations, equivalent and molecular weight determinations, and numerous quantitative experiments with carbon compounds, while some of the common physical methods used in the study of carbon compounds are also discussed. It is not expected by the authors that each experiment described should be performed by each student, but, in their opinion, greater interest is taken in laboratory work when different students are engaged upon different experiments. The book, which is written in a simple and lucid style, and illustrated with excellent diagrams, gives a comprehensive account of the subject, and a student who has mastered it should possess a sound knowledge of the rudiments of organic chemistry.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MAY 5.—"English Furniture Design and Construction." By PERCY A. WELLS. SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

MAY 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India). SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MAY 18.—"Canada as a Field for British Investment." By J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada. The RT. HON. LORD HINDLIP will preside.

Cantor Lectures.

Monday evenings, at 8 o'clock:—

F. W. Lanchester, "Aerial Flight." Three Lectures.

Lecture II.—May 3.—*The principles of stability* —The simple glider—The ballasted aeroplane—Form of the flight path as observed—The flight path as plotted from the equation—The phugoid chart and its teaching—Changes of amplitude of the phugoid curve and influences that lead to such changes—Conditions of flight path, stability and the equation of stability—Effects of propulsion on stability—Influence of the flexibility of the aerofoil—Lateral stability—Rotative stability—The stability of birds and of flying machines in practice—Flight path stability desirable but not essential to flight—Steering in altitude and azimuth—Gyroscopic couples—The boomerang—The gyroscope as an aid to stability.

Lecture III.—May 10.—*The Flying Machine.* —The function and uses of the flying machine—Possible types—The conditions to be fulfilled as defining the type—The need for high velocity—The difficulties of high velocity—The horse-power problem—Motors for flying machines and the conditions governing their weight—Fuels available and the relative importance of fuel economy—Propulsion and the propeller—The use of gearing—The limitations of flight as due to the mode of propulsion—Other modes of propulsion—Wing flapping and its efficiency—Soaring—Starting and alighting—Questions of design and construction—Steering and steering mechanism—Flying at a height—The advantages and disadvantages of altitude—Types of flying machine in practice—The future of flight—The flying machine as a mode of locomotion, in peace and war.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 3... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. W. Lanchester, "Aerial Flight." (Lecture II.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. A. D. Hall, "How Climate and Soil Influence Farm Crops."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. C. A. Battiscombe, "The Influence of Rainfall on the Design of Sewers."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. Clayton Beadle and Dr. H. P. Stevens, "Vulcanisation Tests in Plantation Rubbers." 2. Mr. H. H. Dains, "The Indian Magnesite Industry." 3. Mr. A. Girtler, "A New Steam Meter." 4. Mr. J. Lewkowitsch, "A New Refractometer."

Victoria Institute, 8, Adelphi-terrace, W.C., 4½ p.m. Colonel G. Mackinlay, "The Date of the Nativity was 8 B.C."

Tuesday, May 4...Royal Institution, Albemarle-street, W., 3 p.m. (Tyndale Lecture.) Professor S. Arrhenius, "Cosmogonical Questions." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8½ p.m.

Wednesday, May 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Percy A. Wells, "English Furniture Design and Construction.

Dante Society, 38, Conduit-street, W. Dr. Alnigi Cossio, "Art in Danté."

Royal Archæological Institution, 20, Hanover-square, W., 4 p.m. 1. Professor W. Boyd Dawkins, "Prehistoric York, Durham, and Manchester." 2. Mr. R. Coltman Clephan, "The Early History of Gunpowder, and of the Hand-Gun."

Thursday, May 6...Electrical Engineers (at the House of the Royal Society of Arts, John-street, Adelphi, W.C.), 8 p.m. Mr. H. S. Hallo, "The Theory and Application of Motor Converters."

Royal, Burlington-house, W., 4½ pm.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mrs. Leonora J. Wilsmore, "Some Zoantheæ from Queensland and the New Hebrides." 2. Dr. V. E. Shelford, "The Oecological Relations of the Tiger-Beetles."

Chemical, Burlington-house, W., 8½ p.m. 1. Messrs. A. Findlay, W. E. S. Turner, and Miss G. E. Owen, "Affinity Constants of Hydroxyl- and Aikoxyl- Acids." 2. Mr. E. C. C. Baly, Miss K. A. Burke, and Miss E. G. Marsden, "The Absorption Spectra of the Nitrates in Relation to the Ionic Theory." 3. Messrs. W. J. Jones and K. J. P. Orten, "The Chlorination of Acetanilide." 4. Messrs. J. J. Sudborough and M. J. P. Davies, "Esterification Constants of Substituted Acryllic Acids. Part IV." 5. Mr. F. D. Chattaway, "The Action of the Halogens upon Aromatic Hydrazines." 6. Messrs. M. O. Forster and T. Thornley, "Studies in the Camphane Series." Part XXVI.—"Aryl Derivative of Iminocamphor." 7. Messrs. D. L. Chapman and P. S. MacMahon, "The Retarding Effect of Oxygen on the Rate of Interaction of Chlorine and Hydrogen." 8. Messrs. F. G. Donnan and W. Schneider, "The Colour of Aqueous Solutions of Violuric Acid." 9. Messrs. C. F. Cross and E. J. Bevan, "The Molecular Volumes and Solution Volumes of Colloidal Carbohydrates." 10. Mr. S. J. M. Auld, "An Examination of Irritant Woods. Part I. Chloroxylonine from East Indian Satinwood." 11. Messrs. A. W. Crossley and Miss N. Renouf, "Substituted Dihydrobenzenes." Part III. —"The so-called 1:1-dimethyl- Δ_{2}:5-cyclohexadiene of Harries and Antoni." 12. Messrs. N. L. Gebhard and H. B. Thompson, "Diaz-o-hydroxyl-amino Compounds and the Influence of Substituting Groups on the Stability of their Molecules."

Royal Institution, Albemarle-street, W., 3 p.m. "Aspects of Applied Aesthetics." Lecture III.—"Art and Ethics."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. R. O. Wynne Roberts, "The Past, Present and Future of the Organisation of the Engineering Profession."

Friday, May 7...Royal Institution, Albemarle-street, W., 9 p.m. Major Ronald Ross, "The Campaign against Malaria."

Geologists' Association, University College, Gower street, W.C., 8 p.m. Rev. Charles Roger Bower and Mr. Joseph Richard Farmery, "The Lower Chalk of Lincolnshire."

Saturday, May 8...Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. Raleigh, "Edmund Burke."

Journal of the Royal Society of Arts.

No. 2,946. VOL. LVII.

FRIDAY, MAY 7, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 10, 8 p.m. (Cantor Lecture.) F. W. LANCHESTER, "Aerial Flight." (Lecture III.)

WEDNESDAY, MAY 12, 8 p.m. (Aldred Lecture.) PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S., "The Principles of Heredity as Applied to the Artificial Production of New Forms of Plants and Animals."

THURSDAY, MAY 13, 4.30 p.m. (Indian Section.) KRISHNA GOBINDA GUPTA (Member of the Council of India), "Some Phases of Hinduism."

Further particulars of the Society's meetings will be found at the end of this number.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, June 29th, from 9 p.m. to 12.

The programme of the arrangements will be announced in a future number of the *Journal*.

CANTOR LECTURE.

On Monday evening, May 3rd, Mr. F. W. LANCHESTER delivered the second lecture of his course on "Aerial Flight."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, May 5, 1909; Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Evans, Evan, A.M.I.E.E., Ryan-street, Stratford, Taranaki, New Zealand.
Lane, Frederick, Messrs. Lane and Macandrew, 26, Great St. Helens, E.C.
Mumm, Arnold Louis, 41 and 43, Maddox-street, Bond-street, W.
Perrott, William, B.Sc., Messrs. Johnson and Perrott, Ltd., Nelson-place, Cork, Ireland.

The following candidates were balloted for and duly elected members of the Society:—

de Voss, Mrs. Emilia V., 5, Eichenstrasse, Gross Flottbek, Holstein, Germany.
Forsyth, John Lloyd, West Rand Consolidated Mines, Limited, P.O. Box 38, Krugersdorp, Transvaal, South Africa.
Line, George, Messrs. John Line and Sons, Limited, 213-215, Tottenham Court-road, W.

The paper read was—

ENGLISH FURNITURE: ITS DESIGN AND CONSTRUCTION — ANCIENT AND MODERN.

By PERCY A. WELLS.

Before I show some examples of English furniture on the screen, I should like to say a few things about its production. The title of my paper covers a subject which, in recent years, has aroused a special and wide-spread interest, and received an attention not un-

worthy of its place in the decorative arts. It is satisfactory to feel that the furnishing and beautifying of a house has proved to be a subject of vital worth. Closely allied, as it is, and must always be, with the great mother art of architecture, it embodies some of the finest efforts and traditions of English craftsmanship. I venture to believe, and dare to hope, that those great traditions are not altogether lost; that they still inspire the work of to-day, and must continue to influence the work of the future. Whatever changes have taken place, or may come, the traditions behind a great craft must continue to hold the imagination of the workers in it, whether individual or collective, whether conscious of the fact or not. When that spirit is entirely lost, a craft must become debased, and barren, or cease to exist. I do not mean to say that we have not lost much which appears to be beyond the hope of recovery. Every period of change must bring a profit and loss account, but whether as an ideal to follow, or one to strive after, whether in the workmanship or the studio, these traditions are active forces which work for good or ill in the production of English furniture. It is by the power we possess of giving the highest and best interpretation to those traditions, that its position as a fine craft, and a great industry, must depend.

In furniture we can trace the changes in the social and individual life of the people. What we possess of five hundred years no doubt represents the "survival of the fittest." From the hutch, or chest, of the thirteenth and fourteenth centuries, we have a continuous and fertile growth. By itself, it was bed, seat, table and cupboard. Put upon legs it became the "court cupboard," cabinet, and sideboard. With a back it grew into a settle, settee, and sofa. With the ends lengthened and doors fitted, it lost itself in the press and the wardrobe. All these developments coincide with advances in craftsmanship, culture, and civilised life. In them we note the phases of production, from the primitive worker to the "Guild Brother," and from the "master-maker" to the factory. The work of each period was stamped with the tone and temper of the time, whether of native or foreign influence. Most of it was well designed, and constructed to suit its use. No article was too mean or unworthy of the best that the craftsman could put into it. This is a virtue we have undoubtedly lost, but I am not here to deplore the past, but rather to point its moral for the future, and to see how far it is possible with modern methods to keep alive and continue its best traditions.

We have reason to believe that the strongest and most effective factor in the early work was its more or less individual character, and that the workman had opportunities which he does not enjoy to-day. This, no doubt, was due in part to the lingering influence of the ancient "Guilds," as well as to the larger number of small masters, and the more stringent and all round training of the workman. It is, however, highly improbable that the actual worker was given an absolutely free hand, but it is possible that, having to make a complete piece of furniture from a rough sketch or drawing, his interpretation was more or less individual, as many of the country cabinetmakers must have interpreted Chippendale in the eighteenth century. In our estimation of the old work as against the new we too often forget the changed conditions, and are apt to blame the modern craftsman for many imperfections for which he is not alone responsible. Cabinet-making to-day is a much wider term than it was a hundred years ago. It is not confined to the making of ordinary articles for the house. We now have the most elaborate furnishing for ships and yachts; special furniture for hospitals, museums, and public buildings; all of which has called for as fine a skill as, and a greater resource than, the old workmen could possibly have shown.

From my experience as a craftsman, I can say that there are men in our modern workshops as skilful and intelligent as any in the old, but it has to be admitted that, owing to division of labour and the lessening opportunities of a good training, they constitute a vanishing number. In judging the workman the public are ignorant of the fact that he is not responsible for the design, and not always for the quality of the work, both of which are influenced by conditions over which he has no control. In the manufacture of furniture there are now the designer, the machine, and the workman. It is unfortunate that the workman comes last, for in many cases he is but the finisher of what the machine has done; but, against this, I should like to emphasise the fact that there must always be a great quantity of work which can only be done by hand, with a consequent demand for capable craftsmen.

It may be said here, that modern construction, in the best work, is as good as it can be, and, like the old, it meets the needs and uses of the age for which it is made. We do not need the heavy construction and open joints

of Elizabethan work. A good cabinet-maker of to-day has to make an equally strong joint without showing it.

In broad terms, the furniture being produced now, may be divided into three characteristic classes:—(1) The actual reproduction of historic examples; (2) designs based upon work of past periods; and (3) new work, more or less original, which may be termed "modern." I shall hope to show examples of all these on the screen. The first is a direct result of the revival of Georgian architecture with a demand for furniture in character with it. In the finest work of this kind, the demand must be limited. No pains are spared to make the reproductions as perfect as they can be. In the preparation of designs for decorated or panelled rooms, expensive models are made to ensure the right proportions and correct setting of the details. Commissions for English work of this type come from almost all parts of the world. The best men are engaged upon it, and here it is that they do not compare favourably with the old workmen. The construction is equally good, and probably better, but there is a marked weakness in the form and modelling of curves and shaped sections. Only the other day, the head of a large business house in the West-end showed me some chairs which had come straight from the workshop, and, compared with the model from which they were made, the form and outline were unpleasant to the touch, and did not satisfy the eye. The finish and beauty of outline in a chair is either made or marred by the workman, for the machine can only rough it out. It is just this quality—this quick perception of good form and line—which the old craftsman possessed and the modern one lacks. It is not a question of time or cost, for it takes as long to make a bad curve as it does a good one. It is not all the workman's fault, and it would be difficult to lay a finger exactly on the weak spot, but if English craftsmanship is to hold its own, something must be done to reclaim this essential feature. However highly skilled this work of reproduction may be, it has, I think, one fatal drawback. There is no element of growth in it; it does not stimulate the imagination or tend to progress in art or craft. There is another side to it which is distinctly unpleasant and dangerous to all concerned. The craze for antiques has seriously checked the desire for good modern work, and worst of all it has produced the "faker." Masters and workmen have been driven to this wretched business by the unfortunate whims and fancies of an ill-advised public, and the demands of dealers. Whether good or bad, if it looks anything like Chippendale or Queen Anne, there appears to be a sale for it. Some of it is so cleverly done that even experts are sometimes taken in. There is, however, a clear distinction between a copy of an old example which is frankly a reproduction, and a "faked up" piece which is done to deceive.

On the other hand there is much to be said for that portion of the public who, desiring good furniture, have felt compelled to go to the seventeenth or eighteenth centuries for it. To some extent the designers or makers are to blame for this. The number of people who travel, or who can acquire good taste in furniture, must be comparatively small, and it is to the originators—the designers—that we should look for a lead in this direction. They alone are responsible for the character and style of work put upon the market, and if they wish to lift the trade out of this demoralising business they must be prepared to put something better in its place. Is it not possible to educate the public through the furniture? The great mass of people have no choice but to buy what is put in front of them, and the trade has mistaken a demand for a certain class of work for a change of taste, when no question of taste has been concerned in it.

In the second division we have furniture of all kinds, the designs of which have been influenced by the work of past periods or "styles." And to what a wealth of work may our designers go for their models!—the strong and simple oak examples of the sixteenth and sevententh centuries—the delightful and homely pieces of the Dutch period—and the varied designs of the eighteenth century masters, all of them showing those classic, Italian, or French, influences which were remodelled and fashioned by the English craftsmen for English uses. In them we may discover the essential principles upon which furniture should be made—good proportion, sound construction, right use of material, thoughtful application of ornament, and utility. It is the modern designer's task and privilege to take up those traditions, and use them and adapt them to the needs and conditions of to-day. The materials are more varied than they were a hundred years ago. The construction is better, the machine has to be reckoned with, but it should serve and not dictate, and I think that all round the

opportunities are greater. We have but to take the modern house, either large or small, for change and variety in each room. The question of cost can only affect the quality of material, construction, and finish. Good proportions, good lines, pleasant colour and fitness for its purpose, are features which go to make furniture beautiful, and lift it out of the lower but essential position of bare utility. These features can and should be given to all furniture. They would not cost as much as the overloaded detail and meretricious ornament which has made the bulk of our furniture so commonplace and ugly. They are the very qualities which we admire so much in the old work, and, as they represent principles which only change in their application, I believe it is possible to have them in the new.

Under the third division we have seen an attempt to throw over all tradition, to defy right principles of construction, and to make an improper use of material. I should not have mentioned the "New Art" phase except to show that any movement based upon such lines is doomed to fail. In England it did not go to such extremes as were seen on the Continent, but for a time it had a most baneful influence on the trade. The desire to return to simpler forms was a highly commendable one, and in the hands of thoughtful men it should have given a healthy tone and vigorous lead to better work; but, with some rare and excellent exceptions, the reverse has been the case. Through this movement it was possible to produce the most distasteful and eccentric furniture ever put upon the market. It lent itself to the worst form of cheapness, and was foisted upon the purchaser as an "art" revival. When it is realised that the greater quantity of made-up furniture goes into the ever increasing number of small houses, it is deplorable to think of this wasted opportunity whereby some degree of good taste might have been brought into the homes of the people.

The term "modern," in furniture design, is somewhat vague, and is loosely used to distinguish a type of work largely influenced by the splendid pioneer efforts of the "Arts and Crafts Society." Most of it shows some attempt at original treatment of old forms, with a revival of the simpler types of decoration such as inlaying. A considerable amount of furniture has been designed and made by individual members of the Society, or by "Guilds" of craftsmen, founded upon its principles. Much of it is very good, but in some instances the desire to be original has been carried beyond the bounds of reason. Its influence in the trade has been somewhat limited, but where it has been handled in the right spirit, some excellent furniture has been produced, whilst in the cheaper kinds it has developed into a "shoddy" apology for simplicity.

It is still open for our designers to supply good cottage furniture—by good, I mean simple and strong—as good as the examples now to be found adorning the drawing-rooms of cultured people. These cottage articles have been exchanged for "plush" or "saddle-bag" chairs and flimsy chests, which dazzle the eyes of the poor cottager, and make him only too ready to give up his plainer-looking, though better, things. At the Garden City Exhibition we saw an attempt to furnish cottages, and it must be confessed it was more than disappointing. Only one firm had noted the fact that the most important article in a cottager's living-room was either a bureau or a chest of drawers. As the Yorkshire dresser is in the North, so is the chest of drawers in the South, and I shall be glad to show you a chest designed by Mr. Ambrose Heal which appears to answer the purpose admirably; and to this might be added some bedroom and living-room articles. People who have week-end cottages can usually find suitable furniture for them, but it is something of a crime to rob the real cottager by an exchange which leaves him poorer, and makes him poorer still within six months of the bargain, when he has no chairs to sit upon.

From these conclusions it would appear that the greatest opportunities for progress and betterment—so far as it affects the trade as a whole—are contained in the effort to design and make furniture based on the best traditions of the craft, and brought within the present means of production and distribution. It should give unlimited scope for the highest qualities in design and craftsmanship, and would open out fresh channels for the application of those forms of decoration which are allied to it. More carving might be done, and not be so much confined as it now is, to reproductions, or to work other than furniture. The tendency has been to accept certain styles, and to apply them blindly to any and every type of work and position.

The fine art of marquetry has been almost ruined by its bad design and application to miscalled cheap work, as well as by the unfortunate use of stained veneers. In the

natural woods we have an infinite variety of grades in colour—blues and greens only excepted. With the marquetry cutter as a specialist, it is reasonable to suppose that with good designs and colour it should be possible to equal, if not excel, the Dutch or French work.

Closely allied to marquetry is veneering, or the use of finely figured and rare woods in design, as patterns or diapers, or as a covering for plainer wood. The public are inclined to look upon veneering as being done to deceive them. This may be the case in cheap furniture, but it should be clearly understood that good veneering requires more thought and care in preparation and more skill in execution than what is known as solid work, or that which is not veneered. Many of the woods can only be used in this way and their selection needs the utmost care, whilst in no other form can the highly decorative features of the wood be utilised. We have examples of the Dutch and eighteenth century periods to prove that veneered work can stand the test of time. Here and there some good examples are done, but I do not think our designers take as much advantage of this feature as they might. I have some specimens on the table which have been done by young workmen students under skilled instructors, and beyond the actual practice and training in delicate handwork they afford opportunities for the cultivation of harmony in colour, associated with good design—the application of material to method—and what is also essential from a commercial point of view—the power to get the utmost out of it.

On the subject of material, it is unfortunate that we have no Government Department for testing and classifying the new and numerous timbers which are now being sent into the market. However much a maker may wish to use one or more of them, he must do so at his own risk and without any records to prove its fitness. Any red wood is now sold as mahogany, although it may not possess one of its qualities except colour. There are quite a number of colonial woods suitable for furniture. I have a slide showing a furnished room exhibited at the Franco-British Exhibition by the New South Wales Government. The panelling was made of black bean, a rich brown timber, something like teak but better in appearance. A kind of rosewood, and silky oak—which is prettily figured—were used in making the tables and chairs. The carving was done in white beech, and a carver to whom I gave a sample thought it almost equal to lime. Messrs. George Trollope and Sons, who did the work, speak most highly of all the woods. Africa is also yielding a large quantity of timber, and it would be of the utmost value to the trade if the woods could be tested and classified.

Another neglected feature in decoration I should like to refer to is painting. A great deal is being done in the eighteenth century style on satinwood, and but little—too little—of the delicate Adam's colouring, such as we see on the isolated example—a pier table—at South Kensington. Much of the enamelled work now being made would be vastly improved by the addition of a little colour. For bedroom articles it gives a freshness and daintiness which no other form of decoration can give. Messrs. Heal and Son have recently designed some very successful work of this kind, and there is, I think, room for more. Apart from this purely decorative painting, I believe that the cheaper common furniture would be far better covered with a coat of honest paint than grained, or stained and polished as it is.

I have so far tried to show the possibilities for practical development and betterment, and it may be asked, to what extent are they possible under the present commercial conditions, with a keen competition, division of labour, and the consequent lack of training for the craftsman; to which may also be added the lack of public taste. So far as this last is concerned, I have already mentioned that it must rest with designers to put before the public the best that can be done, in the highest as well as in the commonest work. There is room for the best in all, and I see no reason why the combination of designer and trained workmen, with the machine to serve both, should not produce furniture of good design and within the purchasing power of moderate incomes. The salesman, too, should be perfectly frank with, and gain the confidence of his customer, and assist him to a right selection. It would appear, however, that the greatest power for good rests in the hands of the "buyer," who as a rule is a man of wide experience and exceptional business capacity. He it is who buys stock for the large firms from the actual makers, and it rests with him to accept or refuse the work submitted. If this gentleman were to insist more frequently on better design it would force the makers to employ men who were capable of giving it, and I think his influence alone would go far

in raising the tone of the great bulk of English furniture.

The training of the craftsman has become a national problem. It is admitted on all sides that modern industrial conditions are either too specialised or too strenuous for a lad to get that adequate or sympathetic instruction which should fit him for life as an intelligent and skilled worker. Apprenticeship is ineffective—it exists to a small extent in the furniture trades—but even where it is in operation there is no guarantee of proper training, and boys have to pick up the trade as best they can. The necessity for doing something to take its place has been forced upon the educational authorities. Technical and craft schools have been established to afford instruction in the elementary principles of craftsmanship which the workshops fail to give. I am closely associated with two of these schools, the L.C.C. Shoreditch Technical Institute—situated in the centre of the East-end furniture district—and the L.C.C. Central School of Arts and Crafts in the West-end. In these schools we have classes for young men, who are already engaged in the trade, with instructors who are associated with good firms, either in the studio or the factory. I think everything is done that can be done, through the means of workshop practice, drawing and design, with lectures on materials, methods, and historic periods, to stimulate and guide the efforts of the student. Except for these classes, and the scholarships and South Kensington, there are no special means of encouragement to young designers or craftsmen to study historic art applied to furniture. If the authorities could be induced to offer travelling scholarships to some of our promising students, they would, I am sure, be of material and direct assistance in the development of good design and craftsmanship.

Apart from the classes for evening students, we have at Shoreditch a Day Trade School for boys who are about to enter the furniture and woodworking trades. They come straight from the elementary school and go through a two or three years' training in the principles underlying art and craft work. Their general education is continued and applied in as practical a manner as possible. As the first school of its kind, we believe it has gone a long way towards filling the gap which the decay of apprenticeship has made. The instructors are men with a business experience and an art or craft training, and we hope and believe that boys who go through the school are imbued with some ambition to strive and excel. We realise that such a school has its limits, that it cannot give a boy that measure of experience which can only come to him outside, when he enters a stern competitive system and has to earn his living in it. But we do profess to give him a good start, to train the germs of initiative so that he can take his place as an intelligent starter, with a sound knowledge of what he must meet and overcome. But how small and insignificant even this effort is compared with the enormous number of boys who take up craft work with but little hope of any training!

The position and existence of the furniture industry must depend upon the intelligence resource, and skill of its workers, whether a the desk or the bench. It is to the advantag of all concerned in it, as well as to the genera good, that English designers and Englis furniture should command the admiration c furniture buyers in all countries, as well a the approval of those at home. I am con vinced that if we foster its great traditions- bring into active influence some of the force I have mentioned, and train the craftsman- it will not only gain that approval, bı continue to hold it.

I have selected my slides to show as far a possible the types of which I have spoken, an am indebted to the following gentlemen f the loan of photographs from which the slid have been made:—Mr. Charles Allom, White, Allom, and Co.; Mr. Ambrose Hea of Heal and Son, Ltd.; Messrs. Waring an Gillow, Morris and Company, Geo. Trollope a Sons, Mr. J. S. Henry, Mr. Charles Spoone Mr. B. T. Batsford, and Mr. Hamilton T. Smit

If time had permitted it would have be easy to treble the number of examples. Tho I have shown are representative of the be thought and the finest work. We may fe satisfied that such work is being done in o English workshops. Against it we have put the enormous quantity of middle-cla furniture which is commonplace, and the st larger quantity of the cheaper class which nasty. Even this has to be designed by som body; and, in addition to any suggestions have been able to make, the greatest measu of improvement all round can only come wi a change in the general attitude of mind when it is realised that ugliness is brutalisı and beauty is uplifting. Then, and then onl shall we have the great mass of Engli furniture what it has been in the past—go to make and pleasant to live with.

DISCUSSION.

The CHAIRMAN (Sir George Birdwood) said that before inviting discussion he felt it his duty to offer a few remarks of his own. In the first place he desired to express the extreme pleasure with which he had listened to Mr. Wells's paper, and to say that for his own part he entirely concurred with the views therein expressed. If there was anything he had to say in the way of criticism it was with regard to the slides which had been thrown on the screen, which he thought showed that there was a little over-decoration in English furniture. Speaking personally, he was very simple in his tastes, both with regard to furniture and all kinds of ornamentation. His education had been chiefly in the East, due to his long observation of life in India, and the great principle he had adduced from his experience there with regard to furniture was to do without it as far as possible. The only bed known to the Indian was the carpet upon which he lay and stretched himself at night; chairs and tables he had none, for he sat upon the ground. In a tropical climate one should do with as little furniture as possible, indeed, he would go further and say with as little clothing as possible. But here our furniture was overdone, and our dress was overdone. Further, he desired to say that he felt greater confidence in the taste and skill of the British workman than Mr. Wells apparently did. Ever since the great Exhibition of 1851 he had taken what he hoped was not only an intelligent, but a patriotic, interest in the development of taste in England. It was well known that in Tudor and Queen Anne times, and in the Chippendale and Sheraton period, we led the taste of Europe with regard to furniture, and we were quite as capable of doing that now as then; in fact, we *were* doing it. He considered that England at this moment was ahead of any nation in the world in several branches of decorative and semi-decorative art. No nation could approach us in saddlery, and no nation could approach us so far as men's dress was concerned, though he must admit that we were very backward in the matter of women's dress; while no nation could approach us in the art of furnishing. Mr. Wells had mentioned the fact that the present German Emperor had had his yacht furnished by a London firm, but perhaps it was not so well known that the late German Empress had had the whole of her house furnished from London. There was at the present time a perfect rage for English furniture in France, and our leading cabinet makers supplied unlimited quantities of furniture to the Continent. The same remark applied to pottery. No nation made better china or earthenware than we did at this moment. The only thing in which we were backward with regard to decorative art was jewellery; but we were coming forward in that. In jewellery, ornamentation was everything; but with regard to chairs and tables, it was of prime importance that the article should be useful, and ornamentation must be entirely subordinate. It was noticeable that every form of jewellery shown at the exhibition last year very closely approached the best workmanship of France, and certainly excelled that of Germany. On that account he had unlimited faith in the British workman, and the reason for the apparent decline in public taste was because he did not get sufficient encouragement; but whether it was due to Free Trade or Protection he did not pretend to say. He had been brought up under Free Trade, and he had seen this country made a great Empire by it. It was an undoubted fact that we should never have been allowed to hold Egypt or to extend our Empire in India had we not thrown our conquests open to the whole world. With regard to Free Trade injuring the general trade of the country, diminishing employment, and being injurious to taste he could not say. Personally he was a strong trade unionist, belonging, as he did, to the medical profession, which was one of the strongest trade union organisations; but he was inclined to believe that unionism in this country had affected the efficiency of the workman. It was distinctly a wrong thing that a workman absorbed in his task of tooling a book, or whatever it might be, should be compelled to throw down his tools when the clock struck, and run the risk of a reprimand if he continued to work after a specified hour.

Mr. S. HICKS (Principal of the London County Council Shoreditch Technical Institute) said that though he could not criticise the paper from the point of view of construction, he was keenly alive to the need that the boys in the schools should be versed in the very best examples which could be put before them. Good workmanship generally meant good manhood, and boys who were taught to work well generally became good citizens. He had been very much struck with the lucidity of the author of the paper, and desired to express not only the pleasure he had derived from listening to the paper, but the gratification he experienced at Mr. Wells's reception, inasmuch as he was in daily association with that gentleman.

Mr. H. BATSFORD also desired to thank Mr. Wells for his most interesting paper, and for the very fine slides he had put upon the screen, showing what good work was now being produced in this country. He thought the Society of Arts ought to be very much congratulated in getting a man like Mr. Wells, who knew thoroughly the practical part of his craft, to come and lecture before them.

Mr. C. ALLOM thought that the most important point which English designers had to study and work up to was that of proportion, a quality which had existed in the past, particularly from about 1650 to

1800, but which had largely died out in the present day. He could not help feeling that the sense of proportion was to a very great extent inborn, so much so, in fact, that designers should be reared and live amongst beautiful things. The habit of seeing and living with beautiful things led eventually to the ability of distinguishing between that which was beautiful and that which was not. Mr. Wells's observations on the lack of decoration called, he thought, for some remarks. In the first place the Royal Academy and the painting schools had done so little for decorative art that he could only describe it as a scandal. At the present time painters were lacking work; men had had to drop picture painting for portrait painting, and decorators knew only too well the horrors that were so frequently seen on the walls of the houses. As a decorator he often suffered anguish when he knew that a portrait was going into a room which he had to decorate. He did not wish to praise modern work too highly, but it grieved him to see the appetite which the wealthy people of this and other countries had for purchasing old pictures. The desire seemed to be to buy old pictures, the idea being that as a rule they had more tone and harmony; and having those qualities they became more beautiful to live with. He was sorry to say that too frequently the portraits which he saw in houses lacked decorative quality. He was afraid they were usually painted to have force and to attain great notoriety in the Academy, having in the background an environment which was distinctly calling for force, and perhaps too great force to permit their properly decorating the room. He should like to see the Royal Academy giving more of its attention to decorative painting. Very few men could paint such pictures as hung on the walls of the room in which they were that evening, and he hoped that men like Professor Moira and others would set their influence at work and produce more decorative painting in England. A great deal depended upon patronage. In this country there was no patronage, because there was not the wealth or spending power in luxuries which some other countries possessed, notably the United States. The Chairman had referred to a desire to see very little furniture, and very little clothing. He (the speaker) was disposed to think—he hoped the meeting would forgive him for referring to a political subject, but the Chairman had done so—that if things went on as at present, there would be very little left for furniture or for clothing. Mr. Wells had referred to the salesman's and the buyer's influence, and in that he was perfectly right. If a salesman had not a high ideal it followed that he could not inspire his client with a high ideal. If the salesman had no high ideal he would allow his designers to fall behind. The author had stated that a great load lay upon the salesman and a tremendous load upon the buyer; though he (the speaker) thought more rested upon the designer than upon either. The designer could check a poor salesman, but the poor salesman led the customer astray. One could not have failed to notice the influence of the machine in the examples Mr. Wells exhibited, and it was an influence to which attention might well be drawn. In the old days mouldings were run by hand, and a certain free-hand beauty resulted from the fact that none of the mouldings were geometrically accurate. The work to-day was largely spoiled by the fact that the machine rendered each moulding absolutely true from beginning to end. It had often been said that modelled work had no character. He believed that was largely due to the fact that there were so many books. There were more facilities for travelling and seeing things at the present day than existed years ago, and it was very difficult for designers' development to be along one line as it used to be in the old days. In the days when books were difficult to obtain and photographs did not exist one could hardly fail to develop what was in one's nature; but in these days one had to develop a thing, whether one liked it or not.

The CHAIRMAN said it only remained to him to propose a vote of thanks to Mr. Wells for his admirable paper. He congratulated him first upon the paper itself, and, secondly, on the reception he had received from the large audience which had gathered together to welcome him.

The vote of thanks was carried unanimously.

Mr. WELLS, in reply, said he was delighted that the Chairman and the speakers generally had practically endorsed the views he had expressed in his paper. He agreed within limits with Sir George Birdwood's remarks on the question of simple furniture, and also with what he had said with regard to the English designer. He (Mr. Wells) was proud of the work he had shown, both the cottage furniture and the finer and more ornate examples; and he was extremely anxious that we should be able to continue to hold our own in the future. But there were signs that if something were not done in the direction he had tried to point out, we might not continue to do so. Sir George Birdwood had referred to the influence of trades unions. He should have preferred someone actually connected with the trade to answer the question, but speaking for himself he felt that trades unions were not doing what they might with regard to the training of young apprentices and craftsmen. They were not, he thought, giving sufficient support to the keeping up of the standard of work, but they were giving rather too much attention to the standard of wage. While admitting that from the trade unions' point of view that was necessary, on the other hand he believed that they would be more powerful and do a greater amount of good if they took a wider view of craftsmanship, and gave every possible encouragement to their fellow workmen, and

especially to the younger members of the unions, and so inspired them with the spirit of fine craftsmanship which was so well illustrated in the work and influence of the old guilds, but which the modern trade unionists had entirely lost. He was glad that Mr. Allom, to whom he was much indebted for assistance in the preparation of his paper, agreed with him on the essential points, that the buyer and the salesman and the designer could do more than they did at present. With regard to mouldings, however careful designers might have been in the matter of proportion and details, it frequently happened that the mouldings were spoiled by the men at the mill, for they did not appreciate good form. In conclusion, he desired to thank his audience for the manner in which they had received his paper, and especially Sir George Birdwood for his kindness in taking the chair that evening.

THE GREAT WALL OF CHINA.

Dr. W. E. Geil, author of "A Yankee on the Yangtze," has just returned to his home in Pennsylvania, after a twelvemonth spent in exploring the Great Wall of China from end to end. Although numerous travellers have crossed the periphery of this great structure at various points between the shore of the Gulf of Pe-chi-li, at Shan-hai-kwan, and the deserts in the north-west of Kansu, no previous explorer had ever apparently conceived the notion of following the alignment of the wall and thus forming an accurate and comprehensive notion of its character as a whole. Dr. Geil is now busily engaged in working up his materials, not the least important part of which is a rich collection of photographs, which will illustrate long sections of the wall in localities never before visited by Europeans. In the southern part of the province of Honan the doctor claims to have discovered some remarkable aborigines in the shape of wild men, as well as a race of dwarfs, both these tribes having been driven by the encroachment of the Chinese into inaccessible mountainous tracts. The chief authority on the Great Wall of China, from a historical and scientific point of view, is undoubtedly Dr. O. F. von Möllendorf, formerly of the German Consular Service in China, who, as well as his brother, personally examined several parts of the wall, mostly within a few days' journey of Pekin, and studied very exhaustively all European and Chinese references to the subject, from the earliest records down to those of 1880. Dr. von Möllendorf's treatise is in the "Zeitscript der Deutschen Morgenländischen Gesellschaft, 1881," vol. 35. One of its main conclusions establishes the important point that the Great Wall exhibits and consists of at least four strikingly different styles of construction, and that it is a great mistake to speak of it as a homogeneous structure, dating throughout from great antiquity. The most important section would appear to be that traversing the province of Chih-li, and probably part of Shansi as well, so far as our extremely limited knowledge of the latter country enables one to infer. It consists of a base six yards broad of stone blocks (mostly granite), from which rise two strong walls of large baked bricks or tiles, the intermediate space being filled in with clay, stones, and broken brick-work, and covered or roofed in with bricks. Both sides have low parapets with embrasures, while at irregular intervals rise quadrangular watch-towers. This, the most complete form of the Great Wall, dates from the Ming dynasty (1368-1644), while the other forms are less important and essentially different, and occur in Shansi, Shensi and Kansu. As we know, Dr. Stein found traces of the Wall as far west as Ansichow, while Dr. Geil claims to have discovered a hitherto unknown section to the immediate west of Sining-fu, an identification which finds curious corroboration in a passage in Gouebes's narrative of his travels (*vide* "Astley's Voyages"), where he speaks of the citizens being accustomed to promenade along this Wall as far Su-chow, to the north. There it no doubt that Dr. Geil's work, when published, will shed much useful historical and geographical light on this extraordinary structure which in its various forms has played a very prominent part in the annals of the Chinese Empire.

DEW-PONDS.

Since the reading of the paper on "Dew-ponds," by Mr. George Hubbard, on the 3rd of March last, a good deal of attention has been drawn to the subject. "E. A. M." has contributed an article to "Nature," of the 22nd of April, in which he somewhat controverts the view of Mr. Hubbard that such ponds depend on their water supply from dew, or rather from the condensation of aqueous vapour in the air.

Referring to the well-known method of obtaining ice in India by placing pans of water in shallow beds filled with straw, the writer remarks:—

"This is excellent so far as it goes, and Dr. Wells records that he performed the same experiment in England nearly a hundred years ago. Thus there is a presumption that if straw be laid down under a pond, it may act in such a way as to cut off the heat of the earth below. The difficulty lies in carrying out a similar process on a large scale, and at the same time in keeping the straw dry. Should it become moist, and it must do so if in contact with puddled clay, it will cease to be an efficient non-conductor of heat, and it must be borne in mind that whereas the straw under the ice-pans in India can be, and is, frequently changed, this cannot be done under a pond. Mr. Hubbard says: "In numerous dew-ponds in this country the dew-point is reached without difficulty." Nothing is given in support of this statement, and we may well ask on what evidence it is

based. It presumably means that the water itself reaches a temperature which is below the dew-point. A number of observations made by the writer have never yet revealed the fact. The water of a pond parts with its heat extremely slowly. To be of value toward the replenishment of a pond, the dew must be received in the height of summer, when there is but little rainfall, and when, as is admitted, the ponds at lower levels are drying up. The pond is heated during the day, and evidence is wanting as yet that it falls below dew-point at night. Of course, dew is being received on the grassy banks around, that is to say, on vegetation, but the radiating powers of water and grass are apart as the poles, and on radiation dew-fall, as we know it, depends.

"As Mr. Hubbard states, the altitude of the ponds may result in some amount of condensation, owing to the lowering of temperature resulting from the expansion of the air. This would, however, be but a small factor, whilst the condensation would show itself as mist. There may be something, too, but not much, in the osmotic action of dew-pond water, containing as it does a small proportion of sodium chloride. But there must be some greater factor at work if we are to credit the few records which have been made of the acquisition of, for instance, '3½ inches of water after five nights of heavy dew.'

"Mr. Hubbard rightly judges the importance of the dew-pond principle, if fully established, in countries where there is no natural water supply other than dew. He is also quite correct in dwelling upon the importance of vegetation in increasing the rainfall of a district. But when we hear of the rising of the water in a pond by an inch or more in a night, we desire to know if there are any overhanging trees, and whether there are grasses rooted in the bottom of the pond, with several inches of their growth exposed to the atmosphere. The dew deposited on these would be a large item, and would go to feed the pond. Still, there are undoubtedly some ponds, of large size, with no vegetation appearing above the surface, no drainage except from their own shelving bank, the only visible means of recruiting of which consists of rain and driving mists. Given a period of drought, yet these ponds seem to suffer but little. I am not at all satisfied that straw is really a necessity of the case. I have collected information from several different quarters as to the manner of construction of dew-ponds, but straw is not used in all cases, and when used it is frequently placed above the clay merely to prevent cattle from tramping through the bottom and so allowing the water to escape. If dew-point is reached in the air above a pond, there must be some other factor than the alleged chilling of the clay or the water to bring it about. There is room for more experiment."

There has also been some correspondence in *The Field* on the same subject. This commenced with a letter in *The Field* of March 20th from Mr. Arthur Beckett, in which was given some very interesting information as to the method of making dew-ponds, collected by Mr. Beckett, and supplied to him by Mr. Pickard, the steward of the Glynde estate, near Lewes. According to Mr. Pickard's information, these ponds were constructed of Portland cement and sand, or of mortar into which flints were rammed. Full details are given by Mr. Beckett of the whole process of construction. The ponds in question are not filled by surface water, and he says:—

"During the past few months I have been in correspondence with several scientific students, who have made the thermo-dynamics and hydrostatics of dew-ponds a special study, and have talked with men who have had practical experience of the making of dew-ponds, which they have in many instances kept under close personal observation for long periods. After listening to the many arguments adduced on both sides, and keeping an open mind on the subject, I have been forced to the conclusion that the dew-pond of the downs depends for its water chiefly upon rains, and, in a much smaller degree, on mists and hill fogs, and that dew, *per se*, forms a very inconsiderable factor in the supply."

This view was controverted by a writer signing himself "East Sussex," who described a method of making the ponds out of ground-up and rammed chalk, which set into a hard mass like cement, and was impervious to water. The argument was put forward that the position of these ponds on the top of hills precluded any other source of supply than dew and mist.

Mr. Beckett continued the correspondence in *The Field* of the 24th of April, in which he reiterated the opinion that though hill-top ponds were partly supplied from rain, mists and fog, by far the greater part of the water was supplied by rainfall.

ARTS AND CRAFTS.

Arts and Crafts at the New Gallery.—The greater part of the craft work at the New Gallery this year takes its place, along with the sculpture, in the Central Hall instead of being relegated to the comparative obscurity of the Balcony. This arrangement not only allows the larger works to be seen to better advantage, but proclaims to the casual visitor who is usually thinking of nothing but pictures, that the exhibition is partly devoted to handicrafts. And it must be admitted that the collection as a whole quite justifies its place. The illuminations of Mr. Allan Vigers, if rather coarser than we expect to find in work of this description, are full of vigour and form most satisfactory enrichment to the well printed pages which they adorn; whilst Mr. Howson Taylor, amongst his collection of pots, shows some very interesting examples of crackle. Many well-known metalworkers and jewellers, too, send examples of their work:—Mr. Harold Stabler is represented by a large altar cross and candlesticks as well as a fi

silver and enamel centre piece for the 5th Battalion of the Welsh Regiment; Mr. Paul Cooper has a case of silver work; Mr. Nelson Dawson sends quite a quantity of silver, copper and enamel work, and Mr. and Mrs. Gaskin show a charming little selection of jewellery. Mr. James Cromar Watt exhibits amongst other things a piece of opaque enamelwork which is a wonderful imitation of old Chinese colouring, and a pendant in translucent enamel, portraying a polar bear in arctic surroundings after the design of Mr. John M. Swan. There are a few exhibits in the Balcony. The case of enamelled glass by Miss Nella Casella is well worth looking at, whilst the books bound by Miss Catharine Adams, who has had the happy idea of making dainty little covers for some of the smaller volumes, are admirable examples of bookbinding. Altogether the work on view at the New Gallery forms a show which is very fairly representative of the best that is being done in certain branches of the artistic crafts.

The Building Trades Exhibition.—For anyone who approached it from the point of view of art and craftsmanship the Building Trades Exhibition at Olympia proved rather a bewildering affair. To begin with, the work with some claim to be artistic had to be picked out from amongst a mass of exhibits purely and frankly utilitarian, and again, whilst in some trades the best manufacturers thought it worth their while to exhibit, in others they left the field free to the second class firms, and in yet others many of the foremost makers were content to let their products appear as subsidiary to the exhibits of other trades. Some of the most prominent tile-makers, for example, were only represented by work which occurred in conjunction with fireplaces shown by the various grate makers. For all that, the exhibition had a value as showing not so much the best that can be done in the well-founded and established industries connected with the building trades, but the ways in which various materials are being for the moment most generally employed, and what can so far be done in the newer articles and processes which are coming to the fore.

The various kinds of enamels and paints, washable and otherwise, were somewhat less in evidence than they were two year sago, and there was, perhaps, rather less space devoted to wallpapers and other wall coverings of a similar nature, but of tiling there was a really large show. Messrs. Doulton's stand was mainly noticeable for the sanitary ware, and the exhibit of Messrs. Minton and Co., though it included up-to-date work, was not peculiarly remarkable, whilst the leadless glaze tiles of Messrs. Carter, of Poole, though, in a way, very well worth looking at, did not offer to the unbiassed observer convincing proof of the superfluity of lead as a factor in pottery production. For all that, there was some interesting tiling shown. The surrounds of many of the fireplaces, scattered about the exhibition, contained some really admirable tile designs, and it is satisfactory to note that the regulation set slabs for the sides of fireplaces are not apparently in such high favour as they were some years ago. Side panels want planning, but they do not gain by being treated always too closely on the same lines. Some of the wall tiling, notably that exhibited by the Art Pavements and Decorations, Limited, executed in "Medmenham" tiles from designs by Mr. Conrad Dressler, showed what happy effects can be got from quite simple tiles when their disposition on the wall has been skilfully and tastefully thought out. By the way, most of the most successful wall-tiling schemes seem at present to be carried out in "raised line" tiles. Of glass tiles there was again a large display. The quality of the surface is somehow always rather unpleasing, and the more ambitious efforts in the way of ornament do not seem to have been crowned with success, but some of the dadoes made up of marbled tiles bordered by a simple band of ornament are quite good of their kind. The new mosaic rubber tiling of the India Rubber, Gutta Percha, and Telegraph Works Co., Ltd., was well worth looking at. Rubber tiles, of course, are very pleasant to walk upon, and in this case, as the colours extend throughout the whole thickness of the rubber, the permanence of the designs is assured. The big lily pattern pavement was hardly the happiest thing to attempt in this kind of material, but the tiles lend themselves admirably to simple, rather geometric, designs, and some of the colourings, especially the mottled greens, &c., are very pleasing. This form of floor covering seems, so far, to be rather expensive, but for many purposes it should be not only very useful, but quite as beautiful as its position demands.

The School of Art Wood-carving.—The recently issued report of the year's work at the School of Art Wood-carving affords pleasant reading. There are numerous craft schools and trade schools scattered over greater London, in which many or few crafts are taught according to the needs of the neighbourhood or the conditions of the industries, but a school where both professionals and amateurs can be thoroughly instructed in one craft, and in one craft only, is somewhat of a rarity. Schools, whether owing to the attitude of the teachers or the action of the trade unions, have a way of being filled too exclusively with trade or with amateur pupils as the case may be, to the detriment of both types of students. There is always a danger of trade students getting "trady" and of amateurs being serenely unpractical, and when the two classes work side by side they inevitably and unconsciously rub off some of each other's sharpest corners.

That 53 of last year's students were "trade carvers, professional teachers, or students learning the trade professionally" is a proof of the thorough nature of the teaching given in the school. Again, the fact that during the year the pupils have had the opportunity of trying their hand at work of so practical a nature and on so large a scale as is implied by exe-

cuting or helping to execute orders for, amongst other things, "a staircase, two door cases and a chimney piece" proves that the scholarship boys sent by the London, the West Ham, and the Kent County Councils are getting a training which will more or less take the place of apprenticeship and fit them to be really useful in a workshop when their three years at the school are finished.

The opening for women students seems to be rather in the direction of teaching—and a number of old pupils are at present holding posts in schools or under County Councils in places as widely distant as Kent and Yorkshire.

The quality of the work cannot of course be demonstrated in a report, but the fact that the school's exhibit at the Franco-British Exhibition gained a diploma of honour and was by special request sent out to be exhibited at Buda Pest, speaks for itself; whilst the few pieces of work included in the recent London County Council exhibition at Whitechapel were undoubtedly far and away ahead of any other wood-carving to be seen there. It is to be hoped that in its new home in Thurloe-place the school has before it a career of still greater usefulness than in the less convenient premises in Exhibition - road which it occupied until last Christmas.

The Turnery Exhibition at the Mansion House.—There was a good deal of interesting work to be seen at the Mansion House a few days ago, when the objects entered for the 32nd prize competition promoted by the Turners' Company were on view there. Prizes were awarded to trade competitors for work both in wood and pottery, and a fair number of amateurs competed for the certificates offered in their section. While in most crafts the amateur is, as a rule, far below the level of the trade worker, in turnery his work is distinguished from that done for the trade rather by its extra delicacy and smallness of scale, and by the employment of such relatively costly materials as ivory and tortoiseshell, and the happy combination of various hard woods, than by any lack of technical achievement. Amateur work in this particular instance is, in fact, what its name implies—the work of those who love what they are doing and have leisure to bring it to perfection.' Thus it is not surprising that much of the amateur work shown attained a very high standard of workmanship. It is satisfactory to note that in the various trade classes the prizes seem to have been awarded rather to good - turned shapes well carried out than to more ambitious work which is often far less tasteful and less thoroughly suitable to its purpose. The set of furniture legs included in the work which took one of the highest awards was specially commendable for taste and restraint. Turning is, of course, looked down upon by many artistic folk as a "mechanical" process. But those concerned with the improvement of industrial art would probably do better if they took up a more sympathetic attitude towards it, in view of the fact that many things must inevitably be turned. The exhibition at the Mansion House certainly showed that the trade itself is actively trying to encourage what is best both in design and workmanship.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

STATIC PRESSURE AND COMPRESSION.—Would any reader say what additional pressure per square inch is added to any given depth of water at the bottom of a gas tank when the holder of the gas becomes suspended by the gas it contains?—W. R., Kilmarnock.

CANADIAN AND NEW ZEALAND "WHO'S WHO?"—Are there any books giving information concerning Canadians and New Zealanders similar to that contained in "Who's Who?"—D.

ANSWERS.

FIRE-WALKING IN INDIA.—The following is an extract from the *Pioneer Mail*, of May 25th, 1906:—"Writing about fire-walking, as observed in the worship of village deities in South India, the Bishop of Madras, in the 'Madras Diocesan Magazine,' for May, says:—'A large trench is dug in front of the shrine, about thirty or forty feet long, and ten feet broad, and two or three feet deep. During the morning, this was filled with logs of wood and faggots, which are set on fire, and by the evening become a mass of glowing red-hot embers. After dark, the people assemble with torches, and tom-toms, and music, and then, some thirty or forty people prepare to walk lengthwise over the embers. They are worked up to a great state of excitement by the tom-toms and the shouts of the crowd, and then the whole thirty or forty walk over barefooted, quite slowly and deliberately, in single file, headed by one of the *pujaris*.' This custom of fire-walking is quite common in

Malabar. Kooriche, three miles from Tellichery, in the direction of the French Settlement of Mahe, is a locality reputed for fire-walking. Here a famous *pugari* by the name of Ooochata, dwells. He actually sits on a heap of fire at an annual festival, but is said to be protected by the bark of the areca nut, which is known to be a bad conductor of heat."—W. COLDSTREAM.

FIRE-WALKING IN FIJI.—An interesting article on this subject will be found in *Nature* of December 11th, 1902, where, after a description of the ceremony, the explanation offered by Dr. Robert Fulton is thus summarised:—"The stones took forty-eight hours to get to their 'proper' condition . . . . they were also found to cool very slowly. The same stones are never used twice. They are gradually heated until split by the expansion of the contained water, and are then carefully arranged fractured side upwards. The stone that was examined was an augite-andesite of ordinary type. Prof. Park, of the Otago School of Mines, found that, taking the thermal conductivity of copper as equal to 1,000, that of andesite is 6·67, that is, it is a very feeble conductor of heat. . . . . Thus the fractured, or inside, surface of the stone, owing to its slow conductivity, does not receive nearly the amount of heat one would expect, and, owing to the slow radiation of heat, the foot is not burnt when coming into contact with the stone for a second or less; as a matter of fact the sole of the foot was at no time in contact with a hot stone for more than half a second."—H. G.

NOTES ON BOOKS.

PIONEERING. By Frederic Shelford, B.Sc., M.Inst.C.E. London: E. and F. N. Spon. 3s. net.

This useful little volume consists of four articles which originally appeared in the *Engineer*. They are addressed to "the ever increasing army of young men, such as engineers, surveyors, and public works men, who for the first time are about, for one reason or another, to leave the old country and take up some appointment abroad." Most men in such circumstances are somewhat at a loss to know precisely what sort of outfit it is desirable they should take with them, and many, for want of better advice, are compelled to place themselves in the hands of "outfitters" who frequently furnish them with an elaborate equipment which is as useless as it is expensive. Mr. Shelford, an experienced traveller in many climes, knows what is likely to be essential, what had better be left behind; he deals shortly but effectively with such questions as camp equipment, clothing, fire-arms, medicines, commissariat, and surveying instruments, and he gives some very useful hints on health which should be carefully studied by every young pioneer.

HOMES FOR THE COUNTRY. By R. A. Briggs, F.R.I.B.A. London: B. T. Batsford. 10s. 6d. net.

In issuing the second edition of this work, Mr. Briggs has made considerable additions and effected improvements in the reproduction of some of the illustrations by the "half-tone" process, and the book now contains a series of designs and examples o executed work, with plans of each, illustrated on fifty-four plates. A number of these represent large or moderate sized houses, but there are also many of a less ambitious class suitable for people who are compelled to live in towns, but also desire to keep a small bungalow-house in the country. A few—perhaps too few—words are given in explanation of each plate, and in most cases the approximate cost of the house is stated. Many of the designs are very attractive.

GENERAL NOTES.

COTTON CONCILIATION BOARD.—Representatives of the Federation of Master Cotton Spinners' Associations, and of the Operative Spinners, Cardroom Workers, and Weavers' amalgamations, recently met in Manchester to discuss the proposed framing of a conciliation scheme for the regulation of wages in the cotton-spinning industry. The immediate business of the meeting was to select an independent chairman to preside over future conferences, at which details of the scheme are to be considered. Four names were suggested, and it was agreed unanimously to recommend Sir Edward Clarke, K.C., to the President of the Board of Trade, for appointment; and this appointment has since been confirmed by Mr. Churchill. The choice of a chairman is, of course, only the beginning of a long and complicated task. Much patience and perseverance will be called for before the basis of a conciliation scheme is arranged. The employers and operative spinners are already committed tentatively to an experimental scheme, which has been in operation for a couple of years, but the representatives of the Cardroom Workers Amalgamation are not willing to accept any of the figures of this tentative proposal, without very full reconsideration of the calculations on which they are based. It is earnestly to be hoped that the Conference now sitting will succeed in forming a sliding scale acceptable to all concerned.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MAY 12.—"The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." (Aldred Lecture.) By PROFESSOR ARTHUR DENDY, D.Sc., F.R.S., F.L.S.

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E.

Wednesday afternoon, at 4 o'clock:—

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

MAY 13.—"Some Phases of Hinduism." By KRISHNA GOBINDA GUPTA (Member of the Council of India). SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

MAY 18.—"Canada as a Field for British Investment." By J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada. The RT. HON. LORD HINDLIP will preside.

CANTOR LECTURES.

Monday evening, at 8 o'clock:—

F. W. LANCHESTER, "Aerial Flight." Three Lectures.

LECTURE III.—MAY 10.—*The Flying Machine.* —The function and uses of the flying machine—Possible types—The conditions to be fulfilled as defining the type—The need for high velocity—The difficulties of high velocity—The horse-power problem—Motors for flying machines and the conditions governing their weight—Fuels available and the relative importance of fuel economy—Propulsion and the propeller—The use of gearing—The limitations of flight as due to the mode of propulsion—Other modes of propulsion—Wing flapping and its efficiency—Soaring—Starting and alighting—Questions of design and construction—Steering and steering mechanism—Flying at a height—The advantages and disadvantages of altitude—Types of flying machine in practice—The future of flight—The flying machine as a mode of locomotion, in peace and war.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. F. W. Lanchester, "Aerial Flight." (Lecture III.)

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. A. B. Howes, "Quantity Surveyors: a Review of their Legal Position."

Geographical, Burlington-gardens, W., 8½ p.m. Sir Everard F. Im Thurn, "The Western Pacific."

TUESDAY, MAY 11...Royal Institution, Albemarle-street, W., 3 p.m. (Tyndall Lecture.) Professor S. Arrhenius, "Cosmogonical Questions." (Lecture II.)

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Dr. R. Arthur, "Imperial Emigration and the Problems Connected with it."

WEDNESDAY, MAY 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Aldred Lecture.) Professor Arthur Dendy, "The Principles of Heredity as Applied to the Artificial Production of New Forms of Plants and Animals."

Biblical Archæology, 37, Great Russell-street, W.C., 4½ p.m.

Sanitary Institute, 44A, Margaret-street, W. 8 p.m. Discussion on "The Passage of Excreta through House Drains." To be opened by Mr. H. A. Roechling.

Junior Engineers, at Royal United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Thos. S. F. Gibson, "The Construction of Coin Freed Mechanism as applied to Gas Meters."

THURSDAY, MAY 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Krishna Gobinda Gupta, "Some Phases of Hinduism."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Iron and Steel Institute, 25, Great George-street, S.W., 10½ a.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 5 p.m. Mr. J. G. Millais, "Newfoundland." (Lecture I.)

Electrical Engineers (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m.

FRIDAY, MAY 14...Iron and Steel Institute, 25, Great George-street, S.W., 10½ a.m. Annual Meeting continued.

Royal Institution, Albemarle-street, W., 9 p.m. Prof. G. E. Hale, "Solar Vortices and Magnetic Fields."

Paint and Varnish Society, St. Bride's Institute, Fleet-street, E.C., 8 p.m. Mr. J. Cruickshank-Smith, "The Physics of a Pigment."

Astronomical, Burlington-house, W., 5 p.m.

Malacological, Burlington-house, W., 8 p.m. 1. Lieut.-Col. H. H. Godwin-Austen, "Descriptions of the Animals of Two Land Shells from Perak." (Skeat Expedition in the Malay Peninsula, 1899-1900.) 2. Mr. Edgar A. Smith, "List of Mollusca from Christmas Island, Indian Ocean, and Description of New Species." 3. The Rev. R. Ashington Bullen, "Further Notes on Holocene and Recent Non-Marine Mollusca from Perrangabuloe." 4. Mr. A. S. Kennard, "Non-Marine Mollusca from an Early Neolithic Internment at Cuxton, Kent."

Physical, Imperial College of Science, South Kensington, S.W., 8 p.m. 1. Mr. W. Duddell, "A Bifilar Vibration Galvanometer." 2. Messrs. W. P. Fuller and H. Grace, "Effect of Temperature on the Hysteresis Loss in Iron in a Rotating Field." 3. Messrs. A. Campbell and T. Smith, "A Method of Testing Photographic Shutters."

SATURDAY, MAY 15...Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. Raleigh, "Burke's Prose."

Journal of the Royal Society of Arts.

No. 2,947. VOL. LVII.

FRIDAY, MAY 14, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, MAY 18, 4.30 p.m. (Colonial Section.) J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada, "Canada as a Field for British Investment."

WEDNESDAY, MAY 19, 8 p.m. (Ordinary Meeting.) ARTHUR JOHN BARRY, M.Inst.C.E., "Railway Development in China."

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, May 10th, Mr. F. W. LANCHESTER delivered the third and last lecture of his course on "Aerial Flight."

On the motion of the CHAIRMAN (Professor C. V. Boys, F.R.S.), a vote of thanks to the lecturer was unanimously passed.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

On Thursday afternoon, May 13th, Mr. KRISHNA GOBINDA GUPTA (Member of the Council of India), read a paper on "Some Phases of Hinduism." SIR GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., presided.

The paper and discussion will be published in a subsequent number of the *Journal*.

NORTH LONDON EXHIBITION TRUST.

In 1865 the Committee of the North London Working-classes and Industrial Exhibition (1864), presented to the Society of Arts a sum of £157, the balance of the surplus from that Exhibition, with a view to the annual award of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Prizes were offered to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell, in 1903, and have been continued annually to the present time. These have been awarded, for the present year, as follows:—

First Prize, value £3, to John Allan, for a model design for a memorial.

Second Prize, value £2, to W. W. Meedy, for drawings and examples of copper-plate and mezzotint engravings.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, June 29th, from 9 p.m. to 12.

The programme of the arrangements will be announced in a future number of the *Journal*.

CANTOR LECTURES ON CLOCKMAKING.

The Cantor Lectures on "The Theory and Practice of Clockmaking," by SIR HENRY HARDINGE CUNYNGHAME, K.C.B., have been reprinted from the *Journal*, and the pamphlet (price two shillings) can be obtained on application to the Secretary, Royal Society of Arts, John-street, Adelphi, London, W.C.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, April 29; The RIGHT HON. VISCOUNT MIDLETON, late Secretary of State for India, in the chair.

The CHAIRMAN, in introducing the reader of the paper, said that Mr. Fremantle's credentials for giving the paper were that he had been for nearly twenty years a member of the Indian Civil Service, having filled a number of posts in different districts of the United Provinces. In 1905 he was placed on special duty with regard to the question of labour supply in the United Provinces and Bengal: in 1906 he was charged with some important investigations with respect to Co-operative Credit Societies in the United Provinces; and he was at the present time taking part in the enquiry being held in England, under Lord Sanderson's presidency, with reference to the emigration of Indian coolies to Crown colonies. When he (the Chairman) asked the author to jot down for him the appointments which he had filled, Mr. Fremantle modestly prefaced the list by saying that his career had been a very humdrum one. Mr. Fremantle's attitude was characteristic of a service second to none in the world for ability, assiduity, and succe s.

The paper read was:—

THE PR)BLEM OF INDIAN LABOUR SUPPLY.

By SELWYN HOWE FREMANTLE, I.C.S.

While the question of unemployment occupies so largely the attention of the Western world and many economists almost despair of its solution, it may be refreshing to turn for a time to the Indian continent, where in normal seasons there is work for everyone, and, indeed, constant complaints arise of the difficulty of securing a regular and efficient supply of labour. The fact is surprising enough in view of the density of the population. The average density for the whole continent is 167 to the square mile, and in British India 213.

DISTRIBUTION OF THE POPULATION.

The "Imperial Gazetteer" has an instructive passage on the distribution of the population which I quote here:—

"The greatest density of population is found in the great Gangetic plain, and the next greatest in the narrow fringe of alluvium which lies between the sea and the elevated interior of the Peninsula. As a general rule it may be said that high or low density is concomitant with large or deficient rainfall; but there are of course other factors to be reckoned with. In the western portion of the Gangetic plain the rainfall is not large; but the want is supplied by artificial irrigation from a network of canals, and the land thus supports many more inhabitants than it could otherwise find food for. Much also depends on the character and configuration of the surface, as in the uplands of Chota Nagpur, where there are extensive areas quite unfit for cultivation, and the population is thus very sparse in spite of a fairly copious rainfall. The influence of climate is also well marked, and the malarious "tarai" which stretches along the foot of the Himâlayas possesses far fewer inhabitants than might be expected from its rainfall. Lastly, there are variations due to historical causes, as in Burma, which has but recently enjoyed a settled and civilised government, and which, though half as large again as Bengal and favoured with a good and regular supply of rain, possesses less than one-seventh the population of that Province."

Thus it would seem that except in Burma the population is as great as under existing conditions the country can afford to support. And the population tends to increase *pari passu* with agricultural and industrial development. In the decennial period 1881 to 1891 the increase under favourable circumstances was 9·8 per cent., and even in the period 1891 to 1901, which was remarkable for two great famines and for a severe epidemic of plague, there was a growth of 1·5 per cent. It is true that of the large population nearly two-thirds occupy only a quarter of the area of the whole country, but this is just the tract in which industrial enterprise is most active and complaints of scarcity of labour most frequent. In certain districts, indeed, the density is acute. Thus Dacca, in Eastern Bengal, for purely country districts, takes the lead with a population numbering 952 to the square mile, and the Behar districts of Muzaffarpur and Saran support a population of 917 and 907 to the square mile respectively. These districts are within 400 miles of the busy hives of industry on the banks of the Hooghly, and their surplus population is available to supplement that of Calcutta, which, with Howrah, numbers over 1,100,000 souls. In the United Provinces 36 districts out of 48 have a density exceeding 400 to the square mile, and there are five considerable cities with an average population of 206,000 each. Bombay city had in 1901 a population of three-quarters of a million, and, though the density of its neighbouring districts cannot be compared with that of the Gangetic

valley, the fertile strip along the coast to the south and the plains of Gujerat to the north are well-peopled according to ordinary standards.

Scarcity of Labour in Organised Industries.

All the densely populated districts mentioned are purely agricultural, and they are situated within easy reach of the manufacturing centres. How comes it then that difficulty is experienced by employers in attracting labour to manufacturing and other industrial concerns? The Conference of the Indian and Ceylon Chambers of Commerce on January 6th, 1905, passed a resolution in the following terms:—

"Whereas the supply of rank and file labour for organised industries is inadequate in many districts of India, and whereas the deficiency is seriously restricting the productive power of a large section of the manufacturing concerns of the country, it seems imperatively necessary to this Conference that in order to devise a remedy measures should be taken by a Government Commission or otherwise to investigate the causes which have led to a state of affairs inconsistent with the relative conditions of life of the factory operative on the one hand and the agricultural classes on the other."

In consequence of this resolution, two officers—Mr. Foley, from Bengal, and myself from the United Provinces—were deputed to report on the question of the supply of labour for mills, mines, factories, and similar industries in Bengal and Upper India, and for the handling of goods in Calcutta and elsewhere. In the course of this inquiry we visited the industrial and commercial centres of Bengal and Upper India, and inspected many factories, mills, mines, jute presses, &c., as well as the docks and jetties on the Hooghly. It is chiefly from the experience gained in this inquiry and from the discussions in which it resulted that the conclusions set forth in this paper were formed.

Jute Mills.

In Calcutta and its neighbourhood jute manufacturing is by far the most important industry. It has developed rapidly in recent years, and on the whole the labour supply has kept pace with the increased demand. In 1895-96 the number of hands employed was 78,000, while now it is more than double that number. Some deficiency is no doubt experienced during the hot weather months, as at this time the up-country men prefer to take their yearly or biennial holiday. This is partly due to the introduction of electric light and longer working hours, which have enabled the workers to earn higher wages and made longer holidays both possible and necessary to them. We could not find, however, that the rates of payment for piece-work had risen to any substantial extent in recent years, or that any attempt had been made by managers to induce their men to take their holiday at different seasons. There is no serious complaint of shortage of labour in this industry.

Cotton Spinning and Weaving.

In Bombay and its neighbourhood cotton takes the place occupied in Calcutta by jute. Of 211,711 persons employed in cotton spinning and weaving 148,753 are in the Bombay Presidency. Bombay Island, with 102,000 workers, is the chief seat of the industry, and Ahmedabad, which employs 25,000 hands, is also an important centre. Of the other provinces, Madras, Bengal, the United and Central Provinces all possess cotton mills employing over 10,000 persons. This industry also has expanded very greatly of recent years. The number of spindles, which was under four millions in 1896-97, now exceeds five and a half millions, and looms have increased during the same period from 37,303 to 59,375. There has been no increase in Bengal or in Madras, which are distant from the best cotton-growing districts. In the other provinces the increase has been gradual and fairly uniform. In Bombay and Ahmedabad there has been no general complaint of scarcity of skilled or unskilled labour of recent years, though there have been temporary difficulties owing to strikes and plague epidemics.

In the United and Central Provinces, however, and in Delhi there have been constant difficulties. These have attracted most public attention in Cawnpore, which is the industrial centre of Upper India. In 1900 a serious plague riot occurred in the town. This led to the imposition of a punitive police tax, and we learn from the report of the Upper India Chamber of Commerce that for some time afterwards the supply of labour was most irregular and unsatisfactory. As Mr. McRobert, President of the Chamber, whom I am glad to see in this hall to-night, observed in 1901, "The mill and factory industries have grown at a faster rate than the city has increased in population, and the employers have entered into keen competition with each other for the labour that is available. The workers have not been slow to take advantage of this state of affairs and show their independence by absenting themselves without leave, breaking their agreements without

scruple, in the full assurance that if dismissed at one factory they will readily find employment next door." In 1902 plague was severe in the town, and the effect on trade was disastrous. The President of the Chamber stated:—"During October, November, and December the supply of labour has been less than half of the requirements, in some cases only a third. Workpeople were seized with panic and left the town, but in January most of them returned. It is almost three years now since the labour difficulty assumed alarming proportions, and the plague epidemic merely accentuated the embarrassment." Again, in 1904, the President dwelt upon the continuance of the labour difficulty. When, however, we visited the mills in the following year it was much less acute, and at the present time it has almost disappeared. Enquiries in Cawnpore and in the cities of Agra, Delhi, Nagpur, and Jubbulpur led me to believe that the serious scarcity experienced between the years 1902 and 1905 was due to temporary causes. Several new mills at Hathras and Mirzapur, in the United Provinces, and at Delhi and Lahore, in the Punjab, had been recently founded, and there had been considerable extensions in the Cawnpore and Agra mills. Each new mill as it started work drew on Cawnpore, the oldest established seat of the industry, for its supply of skilled workers, and gave them inducements to leave Cawnpore. At the same time that city was suffering from recurring epidemics of plague, which caused many deaths among the mill-workers and frightened away many more of them to their country homes. Thus, with an enhanced demand for men and a reduced supply to meet it, it is not surprising that a serious deficiency arose. In course of time the supply has, as was anticipated, adjusted itself to the demand, and during the last three years there has been little ground for complaint. At the same time the position from the point of view of employers is unsatisfactory. Similar conditions may again occur, and if they do occur similar results will follow; for the supply of labour, skilled and unskilled, is wholly inelastic, and if a special and temporary circumstance causes a deficiency, experience shows that it is not possible under present conditions to meet it by special measures of recruitment from outside. The reason for this will be discussed later on.

Cotton Ginning and Pressing.

Steam ginning mills have sprung up of recent years in all the cotton-growing districts, and are most numerous in the uplands of the Central Provinces and Bombay. They employ altogether 94,894 hands, more than double the number of ten years ago. These mills work only for the five months of the cotton picking season, and during two only of these months is the work at high pressure. The labour force, which consists largely of women, is generally left in the hands of contractors, who pay so much per unit of cotton ginned. The earnings are good, and, as the mills are generally clustered in groups of three or four round small towns, there is no difficulty in obtaining labour.

Coal Mining.

Coal mining is another industry which has developed greatly in recent years, and now gives employment to 99,138 persons. In 1897 the number was 59,859, and in 1887 only 28,438. Eighty-eight per cent. of the coal is raised in Bengal, nearly all of it in the three principal coal fields—Raniganj, Jherriah, and Giridih. These tracts are hilly, and somewhat sparsely populated. The pits are, moreover, in close proximity to each other, and must, therefore, be dependent in great part on imported labour, which is difficult to attract and more difficult to retain. The labour question has, therefore, from time to time assumed considerable importance. In 1896 a Labour Enquiry Commission was appointed to consider the best means of supplying labour, and made certain recommendations, the most important being a central recruiting agency to bring men down from the United Provinces and Behar. The various companies, however, found it impossible to combine to support one recruiting agency, so nothing was done. In 1905, Sir E. Cable, speaking on the resolution of the Conference of Chambers of Commerce, said:—"I can confirm the statement that labour is becoming more and more difficult to procure, is insisting on higher wages, and is evincing greater willingness to strike on the slightest provocation." Mr. Foley, who visited the coal fields shortly afterwards, sums up the position as follows:—

"I find that there is no scarcity of labour at Giridih and Palamau; in Jherriah more labour is wanted, and, if it were pointed out how this could be obtained without serious trouble and expense, recruitment to a certain extent would be undertaken, but not otherwise. The same remark applies to the collieries in the Raniganj coal field with certain exceptions. The whole question of labour, however, depends on the question of the market for Bengal coal. If only the market were settled no doubt

more coal could be raised, and managers would find it worth while to recruit more miners. There has, however, been so much variation in the past few years that some uncertainty has prevailed, and the output has in some cases been restricted. At the time of writing the coal trade is prosperous, and there is every expectation that the industry will continue to expand so that more and more labour will be required every year."

In the last three years this expansion has continued, and several companies in their last half-yearly reports have alluded to labour difficulties. In default of the establishment of a free flow of labour between the coal mining and the labour districts, the remedy would appear to lie in the more general use of labour-saving appliances—a matter which will be discussed later.

Transport of Goods.

The growth of railways and seaports has created a very large demand for labour. The number of railway servants has increased in the period 1896 to 1906 from 283,095 to 479,284. During the same time the trade of the seaports has risen from 175 to 283 crores, and this expansion must of course mean that many more unskilled workers are required. There has also been, as a result of trade development, great activity in the building and allied industries in most of the towns and cities of India. Sir Herbert Risley, in his Census Report of 1901, states—

"In spite of the great and growing volume of migration, and of the marked improvement in communications which has taken place in recent years, the complaint is universal that the existing supply of labour is wholly insufficient, and that its growing scarcity and dearness constitute a serious drag on the wheels of industrial progress. At certain seasons an unskilled labourer in Calcutta can earn Re 1 daily, and the ordinary rate is from 8 annas to 10 annas for men and from 5 annas to 6 annas for women. It is said that labour is becoming scarcer every year, and quite recently good unskilled labourers in the Calcutta docks were earning Re 1 8 per day. This rate was of course only paid in a time of special pressure, but it shows how slowly under existing conditions does the supply of labour adapt itself to the demand for it."

Our enquiries in 1905, however, did not lead us to take quite so gloomy a view. The usual wages of permanent hands in Calcutta docks were 10 rupees to 11 rupees monthly, a very reasonable rate; while the daily wage of 8 annas is paid for casual labour. There is abundant labour available throughout the year except in April, May, and June. During these months work is not interrupted for want of labour, but higher rates have frequently to be paid. The deficiency in the hot weather months is due to the large proportion of up-country men employed, who visit their homes at this season.

As regards Bombay, I have not been able to obtain any definite information as to the state of the unskilled labour market. The Administration and Census Reports are silent on the subject. From "Prices and Wages in India" it would seem that the average monthly wage of an unskilled labourer is 11 rupees to 12 rupees, much the same as in Calcutta, and that during the last twenty years there has been hardly any alteration. From this circumstance and from the absence of all reference to the subject in official and other publications, it may be assumed that the supply of labour in Bombay has kept pace fairly well with the demand.

Tea Estates.

The labour force on the tea plantations of Assam numbered on 30th June, 1908, no less than 739,795, of whom 452,464 were adults. This province is the great centre of the tea industry, and, as remarked by Sir H. Risley in his Census Report:—

"The indigenous inhabitants, as is natural where land is plentiful, prefer the independence and ease of a cultivator's life to the regular work and discipline of the tea gardens. The total supply of labour is thus wholly inadequate, and the planters, being forced to seek coolies at a distance, have brought into existence the great recruiting business, of whose attendant abuses so much has been heard of recent years, and the suppression of which was the main object of the Labour Act of 1901."

By this Act recruitment was regulated and abuses checked, but service in Assam continued to be unpopular, and in 1904 a large majority of the proprietors of tea estates in the Surma Valley petitioned that free immigration should be permitted to that valley and the special Labour Acts withdrawn. In 1906 a Committee was appointed to review the whole question, and the result was a report published in the following year. The Committee found that, though the arrangements for the comfort of the labourers and the scale of their tasks were generally satisfactory, the local demand for labour was still largely in excess of the supply owing to the remarkable rise of prosperity among the labouring classes in the chief recruiting grounds and the expansion of mining

and other industries. Certain practical suggestions were, however, made for the improvement of existing conditions, and action was taken in the direction of giving greater freedom to the labourers. At the same time recruitment by unlicensed contractors was abolished, and facilities have been given to recruitment by garden sirdars or headmen working under certain responsible associations. The average wage for a male adult is only Rs.5.13.0 monthly, but a woman can earn almost as much. Free quarters are provided, and an agriculturist very much prefers the work to any form of industrial labour. Special inducements have also been given to settle in Assam by the grant by Government of blocks of lands on favourable terms to tea garden managers for this purpose. The aim of the legislative and administrative measures of recent years has been to make the journey to and from Assam easy and the life there attractive so that labour may flow freely in.

Migration.

Certain large industries such as jute and cotton spinning, mining and tea planting, require a large and concentrated supply of labour. It cannot be obtained locally, nor have the towns any surplus labour for export. It can, therefore, only be supplied from the ranks of agriculturists. Now, the Indian peasant is frequently regarded as an immobile individual, who, whether from ignorance or lack of enterprise, continues to slave in his own home at extracting a precarious livelihood from the soil, while, if he were to travel at most a few hundred miles to one or other of the industrial centres, he would find congenial work at good wages. This view is only true to a very limited extent. It is certainly the case that a peasant needs very considerable inducement to cut himself off entirely from his native village. It is for this reason that there is no considerable settled factory population in any Indian city. On the other hand, the peasant is very willing to go to work, and even to take up permanent employment in a distant place on the understanding that his holidays are spent in, and that he retires ultimately to, his native village, and the Census figures afford very clear indications of his willingness. In Upper India the movement of the population is from West to East, and owing to the development of communications and the spread of education it has been very much more pronounced in recent years.

The following figures show the increase in ten years:—

	Persons born in United Provinces enumerated in 1891.	1901.
Bengal (including E. Bengal)	365,000	497,000
Assam	58,000	109,000
Burma	18,000	34,000

In the case of Bengal the fortuitous movement of population between contiguous districts of the two provinces accounts for about one-fourth of the totals in both years. The remaining three-fourths consist almost entirely of servants and labourers who travelled eastwards in search of work.

The resident of the congested districts in Behar is still more ready to migrate than his fellow in the United Provinces. It is South Behar, Saran, and Muzaffarpur, with a population of 12½ millions, from which labour mostly comes. No less than 475,000 persons born in those districts (or one in 26 of the population) were enumerated in 1901 in Central and Eastern Bengal, and of these 120,000 were found in Calcutta alone.

There is also a large volume of migration from the hilly districts of Bengal (Chhota Nagpur, and the Santhal Parganas) and from the Central Provinces to the mining districts of Bengal and the tea districts of Assam.

For the tea gardens statistics of the nationality of immigrant labourers are given in the annual immigration report. The percentages are as follows:—

	Per cent.
Born in plains of United Provinces and Bengal	36
,, ,, Chhota Nagpur, and Santhal Parganas	38
,, ,, Central Provinces..........	16
,, ,, Madras	5
,, ,, Assam	4

For the coal mines no figures are available to show the proportion of immigrant labourers. The workers in the older Raniganj coalfield are usually from the neighbourhood, Bauris and Santhals. Few, however, live close enough to the pits to return home after their day's work; consequently they visit their homes at frequent intervals, and during the season of rice cultivation are absent for lengthy periods. The newer field of Jherriah is situated in a more sparsely populated district, and the labourers come from greater distances. Some workers are brought in from Bilaspur and the Central Provinces, and some from Rai Bareli and Unao, in Oudh.

In jute mills the proportion of up-country

men is very large. Figures kindly supplied me in 1906 by Mr. Nicoll, President of the Jute Mills Association, for three mills with which he is connected are given below:—

	Per cent.
Residents near the mill	22
Immigrants lodging in bazaar	78

	Per cent.
Of whom born in United Provinces	25
" " Behar	41
" " Orissa	5
" " Other districts of Bengal	7

Bombay city is not so dependent as Calcutta on imported labour, but the Census figures here also show a steadily increasing volume of migration. Thus in 1891 one eleventh of the population enumerated in Bombay city were immigrants; but in 1901 the proportion had risen to one ninth, and the immigrants from the United Provinces increased in the decade from 10,000 to 36,000. Burma is a country which has extensive tracts of good land as yet undeveloped, and a people content with the ample returns from their fertile holdings and disinclined to exertion. With the improvement of communications both in India and Burma a wide and growing outlet is afforded for the surplus population of Upper India and certain tracts of Madras. More than half of the population of Rangoon were born on the Indian continent, and settlements of immigrants from India have been formed in some up-country districts.

The migrant population may be said to be almost entirely agricultural, and the volume of migration (as also that of emigration) is sensibly and quickly affected by the character of the season in the labour districts. Thus the increase of 75,000 in the labour force of Assam during the year 1907-8 is attributed mainly to the famine in the United Provinces, while the scarcity in Southern India in the year 1905 led to an unprecedented increase in emigration to Ceylon. The managers of Bengal collieries find their labour troubles temporarily in abeyance when the rice crop in the surrounding districts has been scanty, while any delay in the establishment of the monsoon in the Behar and Benares divisions fills the neighbouring railway stations with passengers bound for the more fruitful territories to the east.

Emigration.

I can only briefly allude to the interesting subject of emigration from India to the British colonies. Emigration from Southern India to Ceylon began more than a century ago, and at the present time nearly one-third of the population of the island (including the whole labour force on the tea estates) is of Indian origin. This exodus still continues, and during the last five years the number of passengers has exceeded that of return passengers by 110,000. Emigration to the Straits Settlements and to the Malay States is of more recent date, and has been greatly stimulated during the last few years by the development of rubber plantations in the States. The Indian population has increased in five years by over 80,000. Emigration to these two colonies is practically free, labour flowing backward and forward of itself; but for the more distant colonies special recruitment in India and indentures to labour are necessary, and elaborate regulations have had to be made to safeguard these proceedings from abuse. Such emigration began with the abolition of slavery in 1834, and the first shipment of coolies to Mauritius took place in that year. To the West Indies emigration was legalised in 1844, and since that date large numbers of coolies have been shipped to British Guiana, Trinidad, Natal, Fiji, and other places, as well as to Mauritius. To all these places they go under indenture for a term of five years, and a large proportion stay on in the colony as free settlers on the expiry of this term. They have been invaluable in supplying labour for the sugar industry, on which the prosperity of each colony so largely depends. In Mauritius Indians now number 261,136, and form 70 per cent. of the whole population. In British Guiana they number 133,665, or 44 per cent., in Trinidad 103,000, or 30 per cent., in Fiji 28,540, or 22 per cent., and in Natal 112,126. Altogether in British colonies, including Ceylon, there are now nearly two million colonists of Indian nationality. But the average number recruited for the distant colonies each year is now only 16,000, and as on the average 7,000 return, the resulting loss is about 9,000 annually. It is obvious that the abstraction of this small number can have no appreciable effect either on the congestion of population in the crowded districts or on the general labour market.

Recruitment.

The only organised labour recruitment in India is that undertaken for the Colonies (including the Straits Settlements) and for Assam. To the jute mills and Calcutta generally there is a free flow of labour from the

United Provinces and Behar. For certain seasonal occupations, however, such as jute-pressing and brick-making, agents are sent at the proper season to secure labour by payment of advances. In these occupations labourers work in small gangs, and the arrangements are made with the head of the gang. There is a natural flow of labour, too, to the Bombay cotton mills, and to the Mysore gold mines, which draw their workers from the coast districts. In the same way labour flows freely to Burma, both from the United Provinces and from the coast districts of Madras, and to Ceylon from the ports of Southern India. Recruitment for the colonies is carried on by agents at Calcutta and Madras, who have recruiters working up country under their supervision. As for Assam, there is now a free flow of labour to some districts, but most gardens recruit through their own *sirdars* or headmen, who are supervised by recruiting associations working in the labour districts. For the coal mines, the Committee of 1896 recommended the establishment of a Central Recruiting Agency at Benares; but owing to the difficulty of combination among the various collieries no action was taken in this direction. Each manager works independently, and has frequently to send one of his staff to bring labour from more or less distant places. Spasmodic efforts at recruitment have also been made for the Cawnpore mills at times when labour was scarce, and though Cawnpore is not far distant from the great recruiting grounds of Gorakhpur and Behar, men have been brought from places as far distant as Ajmere and Alwar. Such isolated attempts at recruitment have seldom been successful. The persons recruited have little idea of the work for which they are engaged. They are not used to any but agricultural labour, and when taken far from their homes and introduced suddenly to the dark recesses of a coal mine or to the noise and whirr of a cotton mill, where all is new and strange, they take alarm and usually desert to their homes or to follow some more congenial occupation. Their tendency to do so is encouraged by the old hands, who resent the introduction of competition from a distance and exaggerate the hardships of their life in order to frighten away the new comers. In such cases it used to be customary to bind the men recruited by agreements under Act XIII. of 1857, but it was soon found that agreements had little effect in holding the workers to conditions which they disliked, and their use has been now almost entirely abandoned. For distant colonies special recruitment is, and probably always will be, necessary, because the great expense and difficulty of communication preclude a natural flow of labour. The development of communications in and with Assam, and the improvement of the condition of the labourer in that province, should in a few years enable it to attract labour freely. No fact was more clearly established from our inquiries of 1906 than this—that in an established industry the workers themselves are the best, and indeed the only, satisfactory recruiting agency. They remain constantly in touch with their homes in the recruiting districts, and if they are content with the conditions of work prevailing in their own industry they will introduce their relatives and friends to it. Those relatives and friends will go under the guidance of the old hand, and with full knowledge of the conditions under which they are to work. And so will arise a constant flow of labour sufficient to meet the wants of that industry, even though it be expanding at a considerable rate.

A remarkable example of this natural recruitment came to my notice when visiting the Warora Colliery, in the Central Provinces, in 1905. One Bhawani Din Dikkit of Bhitargaon, in the Rai Bareli district of Oudh, was in the service of the Great Indian Peninsular Railway engaged on bridge construction, and came to Warora when the first pit was dug there in 1872. Impressed with the earnings which could be made at cutting coal, he went to his home and returned with a few men of different castes. These, being satisfied with their conditions, brought others; and when I visited the colliery, thirty-three years later, this same Bhawani Din Dikkit was in a position of trust, and a free flow of labour between Oudh and this colliery, distant some 700 miles by rail, had been long established. And not only this, but their acquaintance with Warora has familiarised the people of Rai Bareli and the adjoining districts of Unao and Pertabgarh with coal mining generally, and attempts, partly successful, have been made to introduce them to the Bengal collieries; but the conditions there are not so well liked by the up-country men, and it is only to a few of the Bengal mines that a free flow of up-country labour has been established.

Thus the supply of labour for an established industry depends on the conditions of labour prevailing therein. If the conditions are popular, labour will come in of itself, and will

stay. If, however, they be unpopular, special measures of recruitment will have to be adopted. Labour will no doubt be brought in, but at considerable expense, and it will not stay, so that further measures will very soon have to be taken to renew the supply.

Conditions of Labour.

It is only in exceptional cases that the resident of the congested districts who migrates in search of work wishes to cut himself off entirely from his ancestral village. As a general rule it is but one or two members of a family who go, and they want to return as soon as possible. Perhaps the most popular form of labour is that which gives good wages paid at frequent intervals for a few short months of fairly strenuous work. These conditions are fulfilled in the jute presses, brickfields, and docks of Bengal. The work is piece-work, wages are paid daily or weekly, and the season is short. Work is carried on mostly in the open air, and the worker has considerable freedom. If, on the other hand, circumstances in his home are such as to induce a man to emigrate with his family, he settles down contentedly enough to labour in a jute mill, where the work is regular and there is remunerative occupation for women and children. Owing to the prevailing system of working in shifts, hours for the individual are not excessive, and wages are paid weekly. The jute mill worker takes an occasional holiday to visit his home, and looks forward to ending his days in his own country. The cotton mills in Northern India are not so popular with the labourer. The hours are long and sometimes excessive, while wages are paid for one month in the third or fourth week of the ensuing month. Of the rate of wages there is no complaint. Indeed, a writer in the *Pioneer*, in 1905, went so far as to attribute the scarcity of labour then prevailing to the high standard of wages. He argues as follows:—

> "The standard of comfort, the social condition of mill hands in the mufassil is very low: their needs are few and of the simplest. They have no use for money beyond their present needs, and, being improvident in the extreme, when they find themselves in possession of more money than they can spend, they stay away from work till it is all gone and only then return. . . . This ought not to, perhaps I should say would not, occur if there were labour available; but it is not available in Cawnpore, and the only remedy is to import it from outside."

He then goes on to point out how attempts at special recruitment from a distance have failed, a matter which I have already discussed above. But he does not see that the whole question is one of conditions of labour. An analysis of the hands employed in one of the larger Cawnpore mills shows from what a wide area the labour supply is drawn. Of 2,122 persons employed 872 only were born in Cawnpore city. The remaining 1,250 were derived from all the surrounding districts, and there are no less than nineteen districts which supplied ten or more persons to this total. It is, therefore, plain enough that the conditions of labour in Cawnpore must be well known far and wide in the country side, and that if the work were well liked labour would flow in of itself to meet any local deficiency and to force the local hand to attend regularly if he is to retain his employment.

And in this connection the establishment of closer relations between the employer and his men is a very important matter. Conditions cannot be improved or grievances remedied unless the manager is in closer touch with his people. In jute and cotton mills the custom is for the manager to depend on his jobbers (known as *sirdars* or *mistris*) for his labour supply. Now, in Bombay these men are, I believe, drawn from a superior class, and in some cases, at least, have been educated in the Victoria Jubilee Technical Institute, but it is otherwise in Calcutta and Upper India. Here the jobbers are men of the coolie class, who have reached their present position by superior cleverness. The system of depending on them saves trouble to the management, and no doubt has some advantages. For instance, in some of the mills on the Hooghly the coolie lines are owned by the jobbers, and it is to their interest to attract labour to the mills, so that their houses may be filled. But the system is open to great abuses. The worker has to pay a fee to the jobber for engaging him, and is very frequently in his debt. The jobber's control over the labourers is complete, and he can at times dictate his own terms to the management. On the other hand, he is of little service when labour difficulties appear, for it is to his interest to fish in troubled waters. A closer connection of the management with the *employés* would naturally stimulate the provision of suitable dwellings and of schools, the formation of superannuation, pension, and benefit funds, and other measures to improve the condition of the worker, and so lead to the establishment of a full and regular supply of labour, and to the prevention of strikes.

Strikes.

For although there are no trades-unions in India, and associations of mill hands, though some such are in existence, have not as yet succeeded in gaining much influence, so that there is no combination between the workers of different factories, yet strikes in individual mills are by no means uncommon, and they are entered on for the most trivial and insufficient reasons. Thus the Calcutta correspondent of the *Pioneer* reported as follows on the 30th January last:—

> "A curious strike has occurred at Rajganj Jute Mill. Last week the men struck because an European assistant had wounded a boy with an air gun. They demanded the dismissal of the European as a condition of resuming work. This was done, but they now wish the assistant to be reinstated. The management have refused their demands, and a number of men have gone on strike again."

Then political agitation, scares and religious disputes, with which the management have little or no concern, are frequent causes of disturbances among mill hands, and the manager would have much more chance of bringing his men to reason if his relations with them were on a closer and more friendly footing. The Tilak riots last year in Bombay and the Hindu-Mohammedan disturbances in Calcutta at Christmas will be in your recollection, and very serious riots, in which several lives were lost, occurred on the Hooghly some years ago, owing to an unreasoning dread of the enforcement of drastic measures for plague prevention.

Efficiency and Education.

I have but little time left in which to discuss the efficiency of Indian labour, and perhaps it is just as well, as there is no subject on which I have found it more difficult to arrive at definite conclusions. Thus we are told that a female weaver in England looks after six looms, while a male weaver in India can only manage one; but the more usual number of looms per weaver in England is probably three, and it is not uncommon in India for one weaver to manage two looms. In coal-mining, Mr. H. H. Macleod, of the Bengal Coal Company, recently stated that the efficiency of the Indian miner is only one-fifth of that of the Englishman. Chinamen, owing to their industry and avoidance of waste, make excellent carpenters and shoemakers, and very large numbers of them are employed in Calcutta in both capacities. As carpenters they command three times the wages of natives, and in 1905 Mr. R. P. Ashton of Calcutta advocated their introduction for certain highly skilled labour in cotton mills and as overmen in collieries. Nothing has been done to carry out this suggestion. But, on the other hand, it is beginning to be recognised that cheap labour is by its very nature inefficient, and cannot compete with labour-saving appliances.

In the last few years there has been a considerable advance in this direction. Electric cutting plant has been already introduced into some collieries, and a syndicate has been formed to construct a central power station to supply a large portion of the coal-fields with electricity. In many industries hand labour is being displaced by machinery. Cotton is now hardly ever spun by hand, and power-looms have to a great extent supplanted hand-looms. The importance of the hand-loom weaving industry, which is still second only to agriculture in the number of people to whom it gives employment, has, however, received increasing recognition during the last few years, and it is hoped that by the introduction of the fly shuttle and other improvements the efficiency of the hand-loom may be so enhanced as to enable it to compete successfully with the power-loom in certain classes of goods. Even in agriculture labour-saving appliances are making their way. A considerable demand has arisen in the Panjab canal colonies for automatic reapers and winnowers, while throughout India the number of motor pumps and steam flour-grinding and cane crushing machines is rapidly increasing.

Intimately connected with the question of efficiency is that of education, both primary and industrial. In both respects India, and especially Northern India, is very backward, but considerable progress is being made. Primary education leads to greater efficiency and regularity of labour. At present the Indian operative is charged with being indolent when not fully supervised, wasteful of material, irregular in attendance, and without any idea of provision for future wants. There is much truth in the indictment, though slackness and irregularity are a necessary corollary to the long hours for which it is customary to work. And the mill population is, as has been shown above, peculiarly liable to disturbance by ill-founded rumours and unscrupulous political agitation. The main remedy for this state of affairs is primary education, which induces a more reasoning frame of mind, a

higher standard of comfort, and a higher sense of duty. At present the large and increasing factory population is growing up entirely without instruction, and I could wish that the recent Factory Labour Commission had reported definitely in favour of compulsory schooling for half-timers. So long as reliance is placed on a voluntary system it is not likely that much progress will be made. Then, again, there is a general complaint in Bengal and Upper India of the scarcity and inefficiency of trained artisans—carpenters, masons, fitters, turners, moulders, &c. This is a matter which can only be rectified by a large extension of the facilities for industrial education. It is only recently that the subject has attracted the attention it deserves, and something is being done to supply the want. But progress is very slow. In the writer's opinion, vernacular industrial schools, teaching drawing and the use of hand tools, should be established in every district, and industrial classes for apprentices should be attached to all factories where Government work is being carried on. It is in this way that practical and theoretical work can best be co-ordinated, and the leaning of the people to a literary education be diverted to more practical ends.

Conclusion.

I have shown that a marked development is in progress in certain organised industries, and there is also a distinct revival in some indigenous industries; while in agriculture by far the largest industry of the country development is slower, but signs are not wanting that an advance is being made. In many directions, however, development is hindered and hampered: by lack of capital and of enterprise on the part of a few who possess it, by the want of technical and industrial education and perhaps by the absence of a tariff wall, under whose shelter new industries could be created, and decaying industries revived. The normal growth of the population should be sufficient to provide all the extra labour required, and recent improvements in communication have facilitated migration from the congested districts to the great industrial centres. Temporary labour difficulties may, of course, arise, but the Indian worker is tractable, teachable, and adaptable, and no fear need be felt that, given fair conditions of labour and sympathetic treatment, there will ever be a serious shortage of labour in any field of industry.

DISCUSSION.

The Chairman (Viscount Midleton) thanked the author for the admirable digest he had given of the present position with regard to the labour supply in India, and the manner in which he had put forward the result of researches, which had been of a prolonged and important character. It was possible, however, in dealing with the conclusions which the author had drawn from the facts, that those who looked on from a distance at what was taking place in India might arrive at a somewhat divergent and more optimistic view than that entertained by one who had closely studied the question on the spot. In his concluding paragraph the author said:—"In many directions, however, development is hindered and hampered by lack of capital and enterprise on the part of a few who possess it, by the want of technical and industrial education, and perhaps by the absence of a tariff wall, under whose shelter new industries could be created, and decaying industries revived." He (the Chairman) did not intend to carry the audience away to the fruitful field of discussion which was opened by that paragraph, because he had before him the fear of his friend Sir William Lee-Warner, with whom he had the honour of serving at the India Office, and who would be willing to open a battery upon him if he were to attempt to forestall the action of the Indian Executive on that very important and much-disputed proposition. But without going into that subject, he wished to put a little of the burden on the back of the Indian Executive, both at home and in India, whom for obvious reasons the author would not desire to criticise. Nobody could doubt that the labour difficulties which had followed the great development of trade and industry during the last thirty years had largely been accentuated by the fact that the Government of India had not been able to meet beforehand the demands arising out of that development. He did not criticise those who had sat at the India Office or in the Council Chamber in India in the past if they had been in some respects remiss in that particular. They had had to consider finance. At a critical moment in the development they had had a great difficulty to meet in the fall of the rupee. They had had their share of famine, of war and of other drawbacks which had mortgaged their revenue, and had made it unwise perhaps for them to enter on the very large expenditure which must be carried on for a long time ahead. But making all reservations, the fact could not be denied that the railway development of India had been altogether insufficient for the business which that country was able to transact. If a search was made all through the world it would not be possible to find, as far as he knew, any country except China, where such a copious supply of passengers would be found as in India for any new line, and where the whole of the railways paid over 4 per cent. on the capital expended. It stood to reason, therefore, that if in the last thirty or forty years it had been found possible in India to take time by the

forelock, to take advantage of every fall of rate in the City when money was easy to get, if the Indian Government had gone ahead, and spent 10 million a year from 1885 to 1895 and from 1895 to 1905, as was being done now, he believed many of the difficulties which were incident to migration, and the supply of imported labour could have been overcome. The author in the course of his excellent paper had used the word "popular," more than once—the supply of labour would come if the conditions were popular. He did not think he would be controverted by those who knew far more about India than himself if he said that what had to be created in that great matter was not merely popularity; they had to accustom a people who were very sedentary to a change of habit. A great mass of population accustomed to work in places where the pursuits were agricultural had to be accustomed to work elsewhere in pursuits which were not agricultural. This was in itself an enormous change. To accustom Orientals who lounged through a comparatively easy day in their own time to piece-work and to all the incidents of factory and commercial life, would not be accomplished in five or ten years. The author stated that technical education was badly wanted. One of the things in which India had been most backward was that in which this country had also been most backward, namely, technical education, even among the higher classes. He believed he was right in saying that, at the present moment, there was practically no trade education in the proper sense of the term in India at all; and if they wished men of the higher class, who had capital, to embark it in new factories and fresh industries, it was necessary to give them an education, which would show them the advantages of commercial enterprise. That again, was a point where Government had, perhaps of necessity, lagged behind. Once it was realised that the main conditions of communication and education had not been present, they could hardly wonder at the difficulties which the author had found in meeting the needs of a system which was novel with machinery which was obviously out-of-date. There was always the difficulty in trade of the reconcilement of new conditions in the case both of employer and employed. Previously workers had not been able to earn anything like the wages which the author stated had now to be paid. If it were true that one female weaver in England could look after six looms, and one male weaver in India could only look after one, obviously the old agricultural wage would not be far short of the mark. But the author had stated that, when improvement was shown by the workers, it would no doubt pay the employer to give the employed better wages, and thus a desire would be felt by the employed to avail themselves of the larger sum. If the old condition of things were to continue, he had not the least doubt that the tariff reformer in this country would feel a greater security than he now felt against low-priced cotton labour under-selling goods for which the trades unionist had higher rates in this country. In dealing with the labour problem of India, he thought they were not only dealing with a most interesting administrative question, but one of the highest Imperial significance. India was passing through a great phase, in which one of the greatest difficulties had been that to a very large class of people a considerable amount of higher education had been given, but they had been left a very small outlet for their energies beyond agitation. Personally he believed they had, in the highest avocations of trade, an outlook for India which, in almost every Western country, had provided a great class, naturally loyal and naturally conservative in the sense of desiring the preservation of that which they had, and the conditions of law and order without which their economies, trade, and avocations could not possibly succeed. They wanted in India to draw in those who were educated more highly, not only into the paths of law, and, as far as they were fit for it, into the paths of Government, but also into the paths of commercial industry. They would look in vain for any country where men were employed profitably, and had industries and careers open to them, where agitation continued, and where want of contentment and unrest was the order of the day. If illustrations of that nature were required, it was possible to draw them from other countries, but, at the same time, it also gave to those who were exercised about the question a feeling of hope. It was not to be expected that all the difficulties would be redressed in the next decade. For instance, taking this country, if one looked at what Lord Beaconsfield conceived to be the drawbacks to the trade and the conditions of the life of the people in the year 1837, as set out in one of his early novels, "Sybil," one could not help being struck with the picture which he drew. But if one looked further into the matter it would be seen that hardly one of the evils on which Lord Beaconsfield dwelt, were corrected in this country, with a popular Government, before the year 1886. That was a very considerable statement for a Conservative to make, and he called attention to it because it showed that in this, as they hoped the most progressive of all countries, it took fifty years to bring about the amelioration of the conditions referred to, and which brought about a large population eager to avail themselves of the opportunities given them of employment. If that was the case with regard to this country, they must not therefore despair if time was needed in India. To take another instance, in the north of Ireland, most successful and most prosperous industries had grown up, giving a most loyal and contented population, and in the portion of Southern Ireland which possessed the means of communication similar progress was beginning, but almost the same length of time had been necessary to bring it about. He was, therefore, not without hope that, while so great a service had been recently done to this cause by the steady and persistent effort of the Indian Government with regard to railways, by a still more liberal use of technical and trade

education, they would succeed in helping those who were on the spot, in bringing to a successful issue that very great and important question.

Mr. H. LUTTMAN-JOHNSON thought there was no doubt whatever that there was an ample supply of labour in India for any industries which might be started there. The difficulties which had occurred in obtaining labour had been of a temporary nature, and were by no means permanent. For instance, there was no want of capital or labour when one of the greatest industries that existed in India was started, namely, the tea industry. There was no labour in the districts in which the tea grew, but the people who started the industry were able to import labour from other parts of the country, and for many years obtained as much as they required. The system, however, gave rise to certain abuses. It was stated that the coolies were worked too hard, and that they were practically in slavery, so Government interfered, and made it difficult for the tea planters to import labour into their districts. Before a man was engaged to go to the tea districts he had to be taken before a magistrate, which made him think it was a terrible place he was going to, while the name of Assam was also hateful to the Hindu. But in spite of their artificial difficulties and the natural difficulties of the situation, many millions of money had been sunk in the tea gardens, and they were now fairly prosperous. Some people had hoped that the difficulties put by Government in the way of recruiting for the labour supply of Assam would have been removed after the 'Commission's Report, but unfortunately that hope had not been realised. Certain arrangements, which were not very material, as to the conditions of labour in the tea districts had been altered, but the great difficulty that the Government placed in the way of emigration from the labour districts to Assam had hardly been changed, and, as far as he could ascertain, it did not really propose to change them. He gave that as an instance of how, where there was plenty of labour available, the interference of Government, although it might not stop the development of industry in India, might make it much more difficult than it otherwise would be. He thought the best thing to do in regard to such matters was to adopt the Cobdenite principle of leaving things alone, and then it would be found that people would go where they thought they would do well.

Mr. T. J. BENNETT, C.I.E., said that everyone who had any connection with the industries of India could take no other view of the paper than that it was an informing, discriminating, and very cautious survey of the actual state of labour conditions in India. He should not even hint a disparagement of it if he said that it illustrated in some degree a difficulty which was commonplace in dealing with all Indian questions, namely, that of generalising in regard to the economic or any other factor. The author had been very candid in the way in which he had spoken of Bombay. He thought if the terms of Mr. Fremantle's Commission, which were limited to Upper India, had included Bombay he would have given a somewhat different account of the labour conditions in that city than he had done. The last three or four years had been a time of great difficulty in the labour market of Bombay. The pressure just now was not perhaps as great as it was, but he remembered the time within the last three years in which it was almost impossible to obtain coolie labour in Bombay. At one time from 1 rupee to 1 rupee 8 annas was being paid to a coolie, an almost incredible rate of wages, if it was remembered that 6 to 8 annas was a normal rate of pay, even in well-paid Bombay. The reason for that had been possibly because of the prosperity of the city. In a boom in the cotton industry wealthy millowners made more money than they had made for some years, which they put into houses. In addition to that, Bombay had been enlarging its already enormous dock accommodation, something like three crores being spent upon it, and that had made a large demand upon the supply of labour. Those, it might be said, were passing difficulties. Plague might at one time have been included amongst the labour difficulties of Bombay, and those who could look back to the early part of 1897 would remember the aspect of the deserted city when two-thirds of the population had taken flight. As might be well realised, that was a time of exceeding great difficulty. But he thought any employer of labour in Bombay to-day would say that the fear of plague, which was quite distinct from the fear of plague measures, had passed away, and that it was no longer an important factor in the labour problem. Anyone who had acquaintance with the practical side of labour in Bombay would support him in the statement that the difficulties of labour would form a very rich subject for discussion. There was, first of all, what might be called the psychological side of labour difficulties—difficulties connected with the temperament of the people, their distrustfulness, and their suspicion. There was a sort of "hair-trigger" sensibility which had to be respected and carefully guarded against. It was necessary to deal gently with the labourer if one wished to carry on one's operations smoothly. It had also to be borne in mind that in India one was not dealing with the economic man of the old economists—by that he meant a man who, under the stimulus of the expectation of increased gain, would put forward increased effort; and that was a difficulty which differentiated Indian labour problems from those in this part of the world. Illustrations of that sort came before one every day. For instance, if one had a pressure of business, and wished to push through quickly, and offered the labourer an increase of 50 per cent., he would give 50 per cent. less work, and the employer would be the worse off. An illustration of that which came to his own know-

ledge, not long ago, was in a department in a certain industrial establishment in Bombay, which was changed from time work to piece work. The men had been working terribly slowly under the old régime, and they were delighted when it was shown to them that they would double their pay if they worked reasonably well under the new system. Everything went beautifully, and at the end of the first month the men were astonished to find how much they had made. But after two or three months they became dissatisfied; they had nothing to complain of, nothing was wrong, but they preferred the old way. That illustrated the fact that in India they had to deal with status and custom more than with contract. He noticed the author had, towards the end of his paper, referred to various means by which the quality of labour could be improved and labour difficulties could be reduced, one being increased education and the other better housing of the people. He noticed that because the author gave what he thought would be a valuable and efficacious support to an argument that was put forward in Bombay about three weeks ago by the President of the Bombay Millowners' Association, Mr. Fazulbhoy Currimbhoy Ebrahim, a Mohammedan gentleman who, as a captain of industry, reflected credit upon the commercial and industrial life of Bombay and upon the Mohammedan community. That gentleman spoke very seriously indeed of the urgency of the housing question in Bombay. How urgent it was could be realised from the fact that recently a mass meeting of mill workers made a representation to the Improvement Trust in Bombay, impressing upon them the necessity of providing more houses so as to reduce the high rents of the mill hands of Bombay. The education question was also strongly impressed upon the municipality by the President of the Bombay Millowners' Association. Where better housing had been provided there was no doubt that the difficulties of mill management had been mitigated, a millowner in Upper India having told him that he had very little difficulty with his mill hands, for the reason that he had provided them with comfortable housing. The men did not leave their work and go up country as the mill hands in other districts did where proper housing was not provided. He thought it was the fact that industrial labour was getting scarce in Bombay. The old notion that there was an inexhaustible supply of cheap labour in India would have to be revised. He did not think it was inexhaustible and he knew it was not cheap. The mere fact that it had become a question of argument and discussion at the present time seemed to put out of court altogether those who had most confidently year after year said that India was being drained of its wealth, and that it was becoming more impoverished. If there was anything at all in the proposition, which was constantly put forward, that labour was getting scarcer and dearer, the old argument that India was economically deteriorating under British rule had no foundation whatever.

Mr. John Ferguson, C.M.G., said that by far the greater portion of the emigration from India was to the island of Ceylon, which he represented. Ceylon employed more natives of India than the rest of the world put together, a fact which had been an unmitigated blessing, not only to Ceylon, but to the southern districts of India from which the coolies came. He remembered some years ago hearing the late Sir Charles Bernard describe the population of Southern India, from which the coolies were drawn, as numbering from ten to twelve million people, who, if they obtained the equivalent of half-a crown per week per family of man, wife and two or three children, were as well-off as any people on the face of the earth; but inasmuch as in most years they seldom exceeded 1s. 6d. a week, they were always on the verge of distress and famine. The coolies who had come from India to Ceylon were the means of enabling the planters to develop the great coffee industry of the island, the still greater tea enterprise which followed when the coffee industry declined, and also the cocoa (cacao) and the great rubber industry which had now sprung up. The Cingalese, the indigenous population, would not do field work for the planter, devoting themselves to the cultivation of rice and palms, the latter of which was a very large industry in native hands. The rice industry, however, could not supply the want of the emigrant coolies, much less of their town populations, as it was found that the Cingalese, even after the abolition of the paddy rent or tax, had not extended the cultivation. The import of rice from India had in fact more than doubled since the local industry had got a 10 per cent. Customs duty in its favour, and Ceylon paid India now nearly four millions pounds sterling a year for this. The Tamils from India were a most contented people because they were free men. They had no indentured labour, and the planter who was recognised as a good planter by his employers was the man who was popular with the coolies, and obtained an ample supply of labour. Of late years a scarcity of coolies had arisen owing to the rise of the great rubber industry. Two hundred thousand acres of rubber had been put under cultivation, mainly within the last five years, but the difficulty with regard to labour supply had now been overcome, and indeed the Singalese were expected to help in such simple work as collecting the rubber latex or milk, as many of them did the plucking of the tea plant. The coolies who came from the southern part of India stayed for some years and then carried back their savings with them. Those that remained generally had little gardens in connection with their homes in the hills, where they cultivated vegetables. They settled down in the country and the children born to them almost invariably regarded Ceylon as their home. He was thankful that no Chinese had been imported in India or Ceylon, because wherever they went considerable trouble arose in connection with their administration. He entirely sympathised with what the author had said with regard to education.

Those of the people who were educated often rose, became landowners, and useful settlers.

Mr. P. J. HANNON regretted that the author had not referred to the possible influence of the co-operative movement in India on the labour supply. He had been identified for a great many years with the development of co-operation among very poor people. One of the most hopeful effects of this movement was that the spirit of industry and the desire for thrift and work were stimulated. The Chairman had referred to the condition of things which existed in Ireland at one time. He thought that, within the last twenty-five years, there had existed in certain parts of Ireland conditions, from the labour point of view, not very much better than they were in India to-day. There the introduction of co-operation had had a marvellous effect. If one looked back on the work which had been done since the co-operative movement was introduced into India, six or seven years ago, it would be found that very useful influences were at work in the various districts in directing the attention of the Indian peasantry to industrial pursuits. In the Report of the Conference on Credit Societies which took place at Simla in 1906, reference was made to a number of industries to which it was thought the principle of co-operation could be applied. It was suggested in the weaving industry, particularly silk weaving, and the sugar industry, that a co-operative movement might be encouraged with beneficial results. Perhaps the author would be able to state, not merely what had been done in that direction, but how far it was likely that co-operative effort would be successful. At the end of his paper the author referred to the question of a tariff wall being put round India. He did not think it was the province of the Society to discuss the question as it suggested itself to one's mind at the moment, but in the fiscal problem now before the country one of the most difficult considerations was the position of India. It appeared to him to be eminently satisfactory that the Indian labour supply was, at the moment, apparently adequate and well-organised, and it was also intensely interesting from the Imperial point of view, because it would be found, on looking into the rapid development of the sea-borne trade of India, that since 1897 the whole of the trade with all the countries in the world had been practically doubled. In the financial year 1896-7 the total sea-borne trade was 132 millions, in 1905-6 it had risen to 214 millions, and in 1907 to 242 millions. It was very important to know that in a great country developing so rapidly as India was, and affecting as it did the whole prosperity of the Empire, the labour conditions at the present moment were in a satisfactory state.

The CHAIRMAN moved a vote of thanks to Mr. Fremantle for his valuable paper.

Sir WILLIAM LEE-WARNER, K.C.S.I., in seconding the motion, expressed the hope that Mr. Fremantle would print in capital letters the adverb "perhaps" with which he had already qualified his partial approbation of a tariff wall. India's needs for cheap imports, and for open doors to every market in the world for her exports, by which she paid her foreign debt, were imperative. He was very glad to notice the stress laid on freedom of labour. The "sun-dried bureaucrats," of whom we had lately heard so much, could look back with satisfaction on the progress of India from the status of slavery first to a system of contracts, and happily now to the full recognition of the value of free movement of labour at the option of the labourer. The speaker remembered in his time taxes imposed in Native States on men leaving or coming into a village, on marriage with aliens, on goods passing through markets, and generally a comprehensive system of opposition to freedom of men and goods. Now it was perceived that if the conditions suited labourers they would soon come of themselves to new fields of labour without compulsion or even formal contracts. That at least was one of many results of British rule which the Portuguese or the Belgian rulers of over-sea dominions might well take to heart. It was also a healthy note in the excellent paper read which was struck on the subject of education. All large employers of young labour, whether the State or private manufacturers, ought to be obliged to provide the means of acquiring primary education. In asking all present to express their sense of obligation to the author, he would ask them to remember also the Chairman, who by his presence and his speech had added to the interest of an interesting afternoon.

The resolution of thanks was then put, and carried unanimously.

Mr. FREMANTLE, in reply, after acknowledging the extremely kind manner in which the vote of thanks had been proposed and carried, said the Chairman had referred to the lack of the development of railways as one of the causes that hampered the development of industries. Whatever might have been the case in the past in that respect, he did not think it could be said with regard to the present, because there had been a very considerable development in the last 10 years. The congested districts had been very well opened up by railways, and every village was now within 20 or 25 miles of a railway. Of course, the more railways were developed the more opportunities there would be for labour. Mr. Luttman-Johnson had said that certain difficulties still remained to be removed with regard to the free movement of labour to Assam. He was afraid he had not sufficient knowledge of local politics to dispose of that gentleman's objections in any way, although Mr. Luttman-Johnson did not state very clearly what they were. He was very sorry also that he could not answer Mr. Bennett's remarks with regard to Bombay, as he had not any personal experience of that presidency. The remarks which had been made as to the importance of the housing question, especially in Bombay, were

however, very true. He had had a good deal to do with he co-operative movement in India, to which Mr. Hannon referred. There was no doubt of the extent to which the spirit of industry was stimulated by co-operative education and co-operative societies of different kinds. As co-operation extended in the towns, he thought it would do a great deal towards removing the difficulties connected with local labour. Co-operative production had been tried in India, but he was afraid he could not say it had been successful. But they were only at the beginning of things yet, and it was possible that certain productive enterprises might be successful, but so far there was no sign of it. Co-operative education might be joined to primary and industrial education as one considerable factor in inducing a proper spirit of industry.

Mr. G. W. CHRISTISON writes to call attention to the great injury caused to the tea industry in the Darjeeling district, by the recruiting that takes place in the gardens there for the Gurkha regiments, the police, &c. This grievance is, he observes, bitterly resented by the planters, and is a crying injustice, inasmuch as it deprives them of some of their strongest and most skilful men after the latter have been trained at great expense. He strongly appeals to the Government in India to put a stop to the practice complained of. Mr. Christison also points out that a serious scarcity of labour exists in Darjeeling as a result of the famine prices of food in the district during the last two years.

Mr. A. MCROBERT, Ex-President of the Upper India Chamber of Commerce, writes:—I was deeply interested in the paper read before the Society on Thursday by Mr. Fremantle on the "Problem of Indian Labour Supply." Mr. Fremantle is to be complimented on his luminous treatment of a difficult subject. Had there been more time I would have liked to take part in the discussion as my name was mentioned, and I happen to know something of the great pains Mr. Fremantle has taken to get at the views of the workers themselves. The employers are vocal enough but the workers are for the most part dumb, and the results of Mr. Fremantle's laborious inquiry gave an inkling of what is often at the back of the native's reluctance to devote himself to factory work. There is one rather important point that was not alluded to by any of the speakers. In this country an operative who throws up his work is likely to starve, and he knows it. In India the family system gives the coolie the assurance that whatever happens his "brethren" will keep him, and he is, therefore, ready to go on the unemployed list for small reason or no reason at all. The inefficiency of the Indian factory worker was referred to. At bottom this is no doubt to be accounted for by the fewness of his wants and the lowness of his standard of comfort. Accustom him to more comfort in living and he will be more anxious for steady employment. This means higher pay, but not necessarily a more expensive workman, for both the quantity and the quality of the work would be raised. I dare say the average coolie instinctively feels that whatever change he may make he cannot be worse off, and he moves on accordingly. In this country 75 per cent. of a labourer's earnings go in food and rent, the latter amounting to at least three or four shillings a week for indifferent accommodation. In Cawnpore, where I have been in close touch with factory labour for twenty-five years, the worker, for a penny or twopence per week, can get quarters at least as comfortable in relation to his requirements. Two of the larger factories in Cawnpore, have already provided some 1,500 houses of a superior sanitary type which are rented to the workers at twopence per week. These houses are not yet popular—perhaps because they are too good, but the hope is held that the workers will gradually learn to live up to their environment. The effect on the death-rate has been very striking. The death-rate in these settlements for the past three years has been under 25, while the like figure for Cawnpore city and district is over 60. The residents in these villages are also rather more regular in their attendance than those of the workers who live elsewhere. This is just the result which Mr. Bennett expects to follow improved housing. Comparatively short hours of labour do not seem to be any particular attraction. One textile factory in Cawnpore has an average day of under 10½ hours, while others round it nominally run 12 or even 13 hours, and the latter are often actually better off for hands than the former. Workers have been known to throw up their posts in a factory to go on famine relief works. A factory hand is rarely proud of doing his work well. His object first and foremost is to get to pay-day by the easiest possible road. I have probably said enough to show the value of Mr. Fremantle's contribution, although my remarks do not pretend to be anything but sketchy.

NINETEENTH ORDINARY MEETING.

Wednesday, May 12, 1909; PROFESSOR J. M. THOMSON, F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Bishop, Rookwood Comport, J.P., Christchurch, New Zealand.

Chujo, S., 21, Sendagi-Hayashicho, Hongoku, Tokyo, Japan.

Clutton-Williams, J. P. C., Ph.D., F.S.S., care of Messrs. Balmer, Lawrie and Co., P.O. Box 4, Calcutta, India.

Harrison, C. W. Francis, Natal Government Offices, 26, Victoria-street, S.W.

Hay, Lieutenant John A. L., R.N., 13, Little Grosvenor-street, W.
Penn-Simkins, George, care of Messrs. Thomas Cook and Son, P.O. Box 26, Calcutta, India.
Smith, Thomas Fison, 4, McLean's-buildings, New-street Square, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Azam, Khan Saheb Khwajah Mohammud, Dilkosha-garden, Dacca, Eastern Bengal, India.
Clarke, Percy, 13, Fleet-street, E.C.
Goolamhusein, Khan Bahadur H. M. Malak Budrudin, Medhi Bag, Nagpur, India.
Greaves, Mrs., 58, Westbourne-park-road, W.
Guy, Frederic John Vavasour, M.P.S., Kuala Lumpur, Selangor, Federated Malay States.
Habakkuk, William, M.Inst.M.M., 459, Grande Rue, Pera, Constantinople, Turkey.
Hack, Walter P. Pearson, Khartoum, Soudan, Egypt.
Matson, Ralph C., M.D., 1021, Corbett-building, Portland, Oregon, U.S.A.
Menon, T. Kunhi Krishna, B.A., M.R.A.S., Ernakulam, Cochin State, Southern India.
Nakamura, Z., President, South Manchuria Railway Company, Dairen, China.
Nonomura, Kingoro, South Manchuria Railway Company, Dairen, China.
Pet, Maung, K.S.M., Konwindat Quarter, Tavoy, Burma.
Ridsdale, Herbert Wheatley, Hill House, Burnham-on-Crouch, Essex.
Robertson, Lieut.-Colonel D. K., 8, Cadogan-mansions, Sloane-square, S.W.
Sen, Bankim Chandra, M.R.A.S., 17, Charles-street, Haymarket, S.W.
Somake, Moses J. H., McLeod-road, Karachi, India.
Volckman, George William, 197, Sparks-street, Ottawa, Canada.

The CHAIRMAN said that although this was an ordinary meeting of the Society, a lecture would be delivered by Professor Dendy under the Aldred Trust. He hardly thought it necessary to remind those present what that Trust was. It was founded as an essay prize very many years ago by a certain Dr. Aldred, a physician in the Indian Army, and the Council of the Society determined that the money so founded should accumulate until sufficient funds had been provided, and that, instead of an essay, lectures should be delivered as circumstances permitted. That, shortly, was the origin of these lectures. Last year Sir William Ramsay delivered a lecture on his own recent discoveries in Radio-activity, which dealt with the advancement of physical science, whilst this year the Council had gone into another branch of science and had asked Dr. Dendy to give the second lecture. He thought the Society was greatly privileged in getting so distinguished a professor of Natural History as Dr. Dendy to deliver the lecture, for he came before them with experience not only in this, but also in another, hemisphere.

The paper read was—

THE ALDRED LECTURE.

ON THE PRINCIPLES OF HEREDITY AS APPLIED TO THE PRODUCTION OF NEW FORMS OF PLANTS AND ANIMALS.

By ARTHUR DENDY, D.Sc., F.R.S.,
Professor of Zoology in King's College (University of London).

A friend of mine once told me a story of a certain old gentleman who happened to be deeply interested in his family pedigree. His name was an uncommon one, and this in itself was of material assistance in his researches. He had, however, another great advantage which is not shared by many people—he was the fortunate possessor of six toes on each foot. It may not at first be obvious how the possession of an additional toe could assist him in climbing up his genealogical tree and investigating its various branches, but a little episode in his career will make this sufficiently evident. He was visiting a distant country, and was suddenly confronted with his own name over the door of a chemist's shop. He entered, and, finding the proprietor of the shop behind the counter, very politely inquired whether he also had got six toes. We may imagine his delight on discovering that this was indeed the case, and in being thus enabled to restore a long lost branch to the family tree.

It would be difficult to find a better illustration of what is meant by heredity. It is the transmission, from generation to generation, not only of those more general characters which distinguish one kind of animal or plant from another, but also of individual peculiarities which may be very much less conspicuous than the old gentleman's extra toe. Little tricks of habit, so difficult to eradicate in children, may form part of the endowment which they receive from their parents, just as much as peculiarities of feature; and even such a trifling thing as the manner in which you cross your thumbs when you fold your hands together, may be transmitted from one generation to another.

The explanation of such phenomena as these constitutes the most important and at the same time the most difficult problem in the domain of biology, if not in the whole field of science. The history of the progress of mankind is the history of the wresting of one secret after another from the book of Nature, and of the application of the knowledge thus acquired to the control, for the benefit of man, of the natural forces by which he is surrounded.

The investigations of the physical sciences have resulted in an incalculable amelioration of the conditions of human existence, and have at length paved the way for the attack upon those problems which are more particularly concerned with life itself. The conquest and control of the inorganic world are far advanced. The physical forces of inanimate nature are yoked to the service of man; but what of life? How far can we control, how far can we even hope to control the forces which determine the character of living things, the character of man himself? This is the problem before us to-night, and you will at once see that it is of such a nature that we cannot, in the brief time at our disposal, do more than indicate some of the lines along which the attack is being led, and some of the successes which have already been achieved.

The development of any science may be roughly divided into two stages: the observational, in which it is thought sufficient to observe and record what takes place in nature uninfluenced by human interference, and the experimental, in which the observer puts his own finger into the pie, and thereby intentionally modifies the result. Man might almost be defined as the experimental animal, and the same instinct which causes a small boy to throw a stone at a street lamp, for the pleasure of observing the effect of his action, leads also, when properly directed, to the discovery of such things as radium and wireless telegraphy.

Biology is only just entering upon the experimental stage. We have too long been content to take our walks quietly in the dimly-lit streets of nature, without ever troubling ourselves to break a lamp in order to find out where the light comes from.

Observation, however, has enabled us to survey the ground, nor has experiment been entirely wanting. During the last hundred years we have learnt much of the nature of the problem which we wish to solve. Physical and chemical science have led the way, as they always must. The discovery of the microscope and the improvement of microscopical technique have taught us much concerning the physical and chemical composition of living things.

After the discovery of protoplasm, as what Huxley so aptly termed the physical basis of life, one of the greatest intellectual triumphs of the nineteenth century was the elaboration, by numerous biologists, of the cell theory. We know now that the body of every living organism is, with certain apparent exceptions which do not seriously affect the general result, built up of one or more minute nucleated masses of living protoplasm, the cells or organic units. In the simplest plants and animals, for the most part visible only with the aid of a microscope, the entire body is but a single cell, a single speck of gelatinous protoplasm, usually with a differentiated nucleus somewhere near the middle. From this simple condition, through endless grades of ever increasing complexity, we pass to the higher and larger plants and animals, in which many millions of nucleated protoplasmic cells are united together in one individual body and variously modified in structure for the fulfilment of a vast variety of different functions.

We have also learnt that these microscopic cells are capable of self-multiplication by division, and that it is upon this property of the cell that the growth and development of all living organisms depends, for however complex the adult plant or animal may be, it always starts life as a single cell unit, or, to speak more accurately, of a cell unit which is formed by the combination of two cells, the male and female germ-cells or "gametes."

For some time it was supposed that with the discovery of the cell and its nucleus we were approaching the limit of the microscopical analysis of the animal or vegetable body. The researches of the last thirty years, however, have revealed a perfect microcosm of elaborate structure in the nucleus itself, the outstanding feature of which is the appearance, at the time when division is about to take place, of a number of bodies to which, on account of the avidity with which they absorb certain dyes, the name *chromosomes* has been applied. That these chromosomes must be of vital importance to the organism which possesses them is clearly indicated by several facts. Thus they are nearly always constant in number, not only in all the cells of the body but in all the individuals of any particular kind or species of plant or animal, though differing in number in different species; and at every ordinary cell-

division the equitable halving of each individual chromosome is effected by means of a complex mechanism specially adapted for the purpose, in the elaborate process which is termed karyokinesis or mitosis. No less remarkable is the fact that, at a certain period in the life history of each individual, half the number of chromosomes present are thrown out from those particular cells from which the sexual reproductive cells or gametes are destined to arise. Thus it happens that the nucleus of the germ-cell of an animal or plant, whether male or female, has only half the number of chromosomes which we may consider to be characteristic of the species. But before the egg-cell can begin to divide and thus develop into a new organism, it has to be fertilized by the sperm cell. The act of fertilization consists in the complete fusion of the male and female gametes or germ-cells to form a compound cell or zygote. Each parental nucleus brings with it half the proper number of chromosomes, and thus the zygote, or fertilized egg, starts life with a full complement of these bodies, half of which are derived from each parent.

These facts, thus baldly narrated, but established beyond the possibility of doubt, seem to indicate that the chromosomes are extremely important things, and not a few biologists are inclined to regard them as the actual bearers of the characters which an organism inherits from its parents. We cannot say that this view is yet firmly established, but we shall see that it fits in very well with the results of experiments on heredity, and we may at any rate adopt it as a provisional hypothesis. We must be careful, however, to guard against looking upon even the chromosomes, minute as they are, as simple bodies, for each one is probably made up of many thousands of units which are quite beyond the limits of microscopic vision, and it is these that are supposed to be the representatives, so to speak, of the different characters which are transmitted from cell to cell and from generation to generation.

Observation has thus enabled us to establish the existence of a material foundation for the transmission of characters from parent to offspring. We know that every child, if not exactly a chip of the old block, is certainly a combination of chips from two old blocks, and that the protoplasm which forms the material basis of all living things is continuous by means of the germ-cells or gametes, in an unbroken stream from one generation to another. At each act of sexual reproduction, however, two such streams are mingled, and the offspring receives half its initial stock of protoplasm from one parent and half from the other, each half bringing with it all the potentialities which may have been derived from a long line of ancestors.

We must now direct our attention to the results which have been obtained by the experimental method of attacking the problem of heredity. In the early part of the nineteenth century much attention was paid by horticulturists to experiments on the hybridisation of plants, and many such experiments are, of course, still being frequently performed. It was soon found that, within certain limits, it was possible to fertilize the flower of one variety of plant with the pollen of another variety, and in this manner to alter the character of the offspring. Many crosses or hybrids between different varieties were thus obtained, differing in various ways from the parent plants. It was also found that by repeatedly fertilizing the flowers of one variety with the pollen of another the descendants of the first could be entirely changed into the second. This clearly proved that all the distinctive characters of the male parent were in some way represented in the pollen grains, and could be transmitted by these to future generations, but it also proved something more: it proved that it was possible to eliminate the special characters of the female parent, or at least to prevent them from manifesting themselves in the offspring.

We must remember, of course, that the process of fertilization in plants, as in animals, consists essentially in the union of two sexual cells, or gametes, of which the female egg-cell is contained in the so-called "ovule" in the "ovary" of the flower, and the male sperm-cell in the pollen grain.

As a rule it is only possible to bring such experiments to a successful issue when working with closely related species or varieties. The flower of one kind of orchid, for example, may perhaps be fertilized by the pollen of a different orchid, but the pollen of such a plant as a lily would probably not have the slightest effect upon it.

The first observer to throw a clear light upon the meaning of the remarkable results obtained by hybridization was Gregor Johann Mendel, a native of Austrian Silesia, born in 1822, whose work has recently attracted so much

attention. As Abbot of Brünn, he was the happy possessor of a garden, and presumably also of that peace and quiet which are so essential to intellectual work. He was not content with merely casual experiments in hybridization. In the seclusion of his cloister he had time to think about what he was doing, and he attacked the problem in the true scientific spirit. Unfortunately for science, however, his seclusion was a little too complete. He was content to publish his results in 1865 and 1869 in the proceedings of a local natural history society, where they remained buried and almost unnoticed for more than thirty years. Thus, by the irony of fate, our own illustrious countryman, Charles Darwin, the hundredth anniversary of whose birth we celebrate this year, never heard of those remarkable discoveries which bid fair to solve some of the problems in which he himself was so deeply interested.

In order to gain an insight into the nature of Mendel's work, we cannot do better than turn to his original memoir, entitled "Experiments in Plant Hybridization," of which an excellent translation has been published by Professor Bateson, the leading exponent of what is now termed Mendelism in this country. Even fifty years ago, experiments in hybridization were, as we have already seen, no new thing. Mendel had many predecessors in this line of research, but it was reserved for him to introduce exact statistical methods into the work, and it is to these methods that he owed his success. It was already known that hybridization, or the crossing of distinct species and varieties, might produce and very often did produce several distinct types of offspring from the same parents. Mendel was not content with this knowledge: he proceeded by numerous and often repeated experiments, extending over several years, to classify the offspring produced by hybridization, to follow out their descendants from generation to generation, and above all to find out the exact numerical proportions in which the different types appeared in successive generations. It was the discovery of these proportions that furnished the clue to the mystery.

Mendel found the material which he required for his experiments chiefly in the numerous garden varieties of the common edible pea. How these varieties first originated we do not know. Probably they arose as sudden and apparently spontaneous variations, or as Professor Hugo de Vries terms them, *mutations*. No less than twenty-two such varieties were selected for experiment.

The next thing he did was to select certain differentiating characters upon which to concentrate his attention, and this is a very important point. Of course, all the varieties agreed with one another in most of their characters, in other words, they were all edible peas exhibiting the specific characters of the plant known to botanists as *Pisum sativum*, but they differed in numerous minor features. Of these differentiating characters Mendel selected seven for the purposes of his experiment, amongst which I need mention only two: (1) the form of the ripe seed, which, roughly speaking, may be either round and smooth or angular and wrinkled; and (2) the difference in colour of the contents of the seeds or cotyledons, which may be either yellow or green.

The two differentiating characters of each pair were artificially united by cross-fertilization, the flowers of a round-seeded pea being fertilized by the pollen of a wrinkled-seeded pea, those of a green-seeded pea by the pollen of a yellow-seeded pea, and so on.

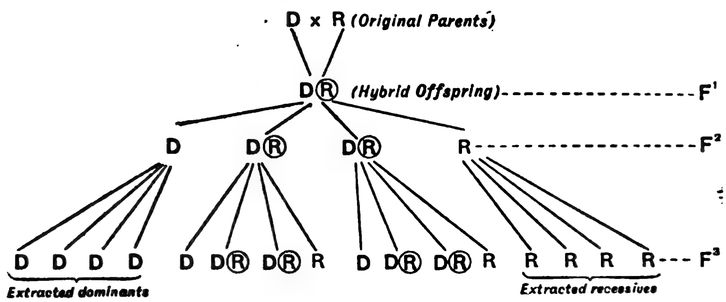
In this way a number of hybrid plants, represented in the first instance by seeds, were obtained, and the curious fact was observed, that each hybrid closely resembled one of the two parents, instead of being, as is frequently the case in other hybrids, intermediate in character between them. Further experiments with the offspring of the hybrids, however, showed that, although only one of the two contrasted characters manifested itself in the hybrid, the other was there also in a latent or dormant condition, and appeared again in subsequent generations. The character which appears in the hybrid is said to be *dominant*, while that which is suppressed is said to be *recessive*. In the case of these peas, then, one character was always dominant over the other in the hybrid, and, moreover, it was always the same character, and it did not matter whether it was derived from the male or from the female parent. Thus the round form of seed is dominant over the wrinkled, the yellow colour of the seed contents over the green, and so on.

Having obtained the hybrids, the next step was to follow the history of the offspring throughout successive generations. For this purpose the flowers of the plants raised from the hybrid seeds were allowed to fertilize themselves with their own pollen, no further crossing being permitted. The seeds thus obtained were now again apparently of two kinds, re-

sembling the two original parent forms from which the hybrid was produced. Moreover, these two kinds occurred in definite proportion, three of the dominant to one of the recessive—three round seeds to one wrinkled, three yellow to one green, and so on. Of course, these proportions are only averages, and in order to eliminate errors of chance, large numbers of observations must be made—the greater the number the more reliable the result. To take an actual example from Mendel's work, 7,324 seeds were obtained in the second trial year from the hybrids between round and wrinkled. Of this number, 5,474 were found to be round, and 1,850 wrinkled—showing the ratio of 2·96 to 1. Again, out of 8,023 seeds produced by the hybrids between green and yellow, 6,022 were yellow and 2,001 green, the ratio being 3·01 to 1. These experiments have often been repeated during recent years, and it is found that the average ratio of three to one is always maintained.

The significance of this proportion is not at first sight obvious. It is necessary to continue the experiment for at least another generation in order to gain further insight into the matter. We have as the result of the self-fertilization of our hybrids apparently only two kinds of seeds or plants, which we may call D, showing the dominant character, and R, showing the recessive character, in the proportion of 3 D to 1 R. If these plants are again cultivated and allowed to fertilise themselves we find that every one of the R's breeds true, and no matter how many generations we raise they will always remain of the recessive type. These are now called extracted recessives. When, however, we cultivate the plants showing the dominant character in the same way we soon find that though similar externally they are not in reality all alike, for one-third of them will yield nothing but D's, while the remaining two-thirds will yield D's and R's in the same proportions of 3 to 1 as the original hybrid. Moreover, the D's obtained from the one-third will continue to breed true from generation to generation, and do what we will we can never get an R out of them again. They are called extracted dominants.

It is obvious, then, from these experiments that the apparent D's are not all true D's, but that two-thirds of them contain the recessive character in a latent or dormant condition, and are, therefore, still hybrid in composition. If we indicate those which we can thus prove by breeding to contain the latent character by the letters D (R), we can sum the whole story up in the following simple diagram :—



Thus we see that from generation to generation of the offspring of the hybrid there goes on a constant sorting out into three categories, the two original parental types and the hybrid form being always produced in definite proportions. If we assume that each kind produces on an average an equal number of offspring, we shall see from the diagram that in the course of a few generations of undisturbed reproduction by far the greater number of the plants will have finally reverted, in equal proportions, to one or other of the original types, but a certain number will always remain in the hybrid condition and will continue to split up as before in the well-known Mendelian proportions.

We see, then, from Mendel's experiments, that in the case of peas, where one of the two contrasted characters is dominant over the other, the offspring of the first hybrid appear in the proportion of three apparent dominants to one recessive, but that further analysis shews that the real proportion is

1 D : 2 D (R) : 1 R.

This proportion has since been observed not only in peas but in a large number of other cases, including animals as well as plants. It is evidently a phenomenon of very common occurrence, though we cannot as yet say that it occurs universally whenever two forms with

contrasted characters are crossed. Moreover, as we have already noticed, the phenomenon of dominance is not always shewn, and the hybrid may exhibit a character intermediate between those of the two parents or different from either. The occurrence of the Mendelian proportions, however, is sufficiently frequent to demand explanation, and this explanation we must now seek.

Suppose we take a large number of black and white counters, all alike in shape and size, and after shaking them up thoroughly in a bag, draw them out two at a time without looking. Each pair that we draw out may consist of two whites, two blacks, or a black and white. If we draw out a sufficiently large number of pairs entirely at random in this way and then count them, we shall find that they occur in the proportion

1 BB, 2 BW, 1 WW,

or one all black, two black and white, and one all white, this being, of course, only what is to be expected in accordance with the mathematical law of probability. This is also the same as the Mendelian proportion, and at once suggests that the latter may, perhaps, be explained in a similar way as the result of random union of characters in accordance with the laws of chance.

We know that each individual plant or animal produced by sexual reproduction is formed by the union of two germ-cells, or gametes, a male and a female. Now these gametes are formed in very large numbers in the parent organism, and if we suppose that each one, whether male or female, contains only one of the two contrasted characters with which we are experimenting, and if we further suppose that they unite at random, male with female, then in accordance with the law of chance we should expect to get in the offspring the proportion, of one with the one character, two with both characters and one with the other character, exactly as Mendel found in his experiments. There seems to be no other possible explanation of the Mendelian phenomena.

The conclusions to be drawn from these results are of fundamental importance. In the first place, we learn that small individual characters may be separately represented in the germ-cells and separately transmitted from parent to offspring. This indicates that the entire organism may be built up of a number of unit characters, and if we can once establish the general occurrence of such unit characters we shall have taken a long stride towards the understanding of the laws of heredity.

In the second place, we may conclude from these experiments that, as regards the unit characters with which we are dealing, we have a complete segregation amongst the germ-cells or gametes, each of which carries only one of each pair of contrasted characters (technically termed allelomorphs), and in this respect it makes no difference whether the germ-cell be male or female. Thus we arrive at what is sometimes termed the doctrine of the purity of the gametes—purity, that is to say, with regard to each character of any such contrasted pair and without reference to the other innumerable characters which must be represented in the germ-cells in order that the whole complex structure of the organism may be developed from them.

Of course, it is extremely improbable that any two varieties which are united in the formation of a hybrid will differ from one another only as regards one pair of contrasted characters. There will almost certainly be more than one such difference between them, and our experiments will be complicated accordingly.

I now propose to give you two examples of a class of practical problems which have been solved by the application of Mendelian principles.

The first case I borrow from the Reports to the Evolution Committee of the Royal Society, the second arises directly out of Mendel's own work. Some of you may be acquainted with a particular breed of fowl known as the blue Andalusian. It has long been known that this kind of fowl cannot be made to breed true. Some of the offspring will be white and others white with black splashes, the remainder being like the parents. It has been shown, moreover, that the three kinds of chicken occur in definite proportions, a quarter being black, a half blue, and a quarter black and white. Here we have the familiar Mendelian proportions 1 : 2 : 1, suggesting that the blue Andalusian is really a hybrid, and that the so-called "wasters" are the parent forms. It is easy to prove that this is the case, for if the two kinds of wasters are mated we invariably get the blue Andalusian again. The old idea of the so-called practical breeder would have been to go on destroying the wasters and carefully selecting the blues in order to maintain the "purity of the breed." We now know, however, that there is no such thing as a pure blue Andalusian breed: the

blue is really a hybrid, and you can get more blues by mating the wasters than by breeding from the blues themselves. This case is also theoretically interesting as affording an example of a hybrid which differs in character from either of the parent forms.

The second example is one which shows us how, under certain circumstances, we can obtain a hybrid exhibiting an entirely new combination of characters, which in spite of its hybrid nature will continue to breed true.

Suppose a gardener had only two kinds of peas, one with round green seeds, and the other with wrinkled yellow seeds, and that, as usual, he wanted something that he hadn't got, say peas with wrinkled green seeds. Mendel has shown us how he may get what he desires, both surely and speedily, from the material already in his possession.

The necessary procedure will be evident from the following scheme :—

Let R = round, W = wrinkled, Y = yellow, and G = green. We know from previous experiments that R is dominant to W, and Y to G.

R G crossed with W Y, gives the hybrid, R (G) (W) Y, which owing to the dominance of R and Y will appear in the form of round yellow seeds. That is not what our gardener wants, and if he knew no better he would naturally be much disappointed with the result. If, however, the hybrids be allowed to fertilize themselves and reproduce, then their offspring will appear in the proportions :—

9 R Y : 3 R G : 3 W Y : 1 W G.

This is a case of what is termed di-hybridism, in which two pairs of contrasted characters, or allelomorphs, are concerned. The proportion 9 : 3 : 3 : 1 exhibited in this case is partly due to the phenomenon of dominance, and will be readily understood from the accompanying Table :—

Germ cells → ↓	R Y	R G	W Y	W G
R Y	R Y R Y	R (G) R Y	(W) Y R Y	(W) (G) R Y
R G	R Y R (G)	R G R G	(W) Y R (G)	(W) G R G
W Y	R Y (W) Y	R (G) (W) Y	W Y W Y	W (G) W Y
W G	R Y (W) (G)	R G (W) G	W Y W (G)	W G W G

The constitution of the hybrid is R G W Y. Each of its germ-cells or gametes contains one character, and one only, from each contrasted pair. It may, therefore, contain R + Y, R + G, W + Y, or W + G. These different kinds of germ-cells will occur on the average in equal numbers, and on self-fertilization (R G W Y × R G W Y) they will unite in pairs at random. The possible ways in which such union may take place are shown in the Table, and if allowance be made for the phenomenon of dominance, in accordance with which G disappears from view whenever it meets Y, and W whenever it meets R (as indicated by the brackets in the Table), we get the apparent proportion of 9 round yellow seeds, 3 round green seeds, 3 wrinkled yellow seeds, and one wrinkled green seed. The number of wrinkled green seeds will be small at first, but they will breed true, containing as they do only the extracted recessive characters, for if a dominant character were present it would necessarily show itself.

Thus we see that one way of producing new forms of plants and animals is by the artificial combination of desirable characters which already exist in different varieties. These elementary or unit characters can be brought together by the process of hybridization, and new organisms produced in much the same way as the chemist is able to produce new compounds by analysis and synthesis from other substances.

Probably no man has made more successful use of the process of hybridization in the production of new and valuable forms of plant-life than Luther Burbank, at his celebrated Californian nurseries. Burbank himself is unfortunately not a writer, and for a scientific account of his work we are indebted to the distinguished botanist Hugo de Vries. In his delightful little book on "Plant Breeding," Professor de Vries describes what he himself saw and heard during his visits to Mr. Burbank's farms. It is not necessary for me to enter into details with regard to the marvellous results which Mr. Burbank has obtained. Some idea of their commercial value may be formed from the fact that special companies have been formed for the propagation and sale of some of these wonderful hybrids. White blackberries, stoneless prunes, "plumcots," and thornless cacti are only some amongst the many novelties which he has produced by crossing different varieties by hybridization and thus combining two or more desirable qualities in one plant.

Take, for instance, the case of the stoneless prune. It had somehow or other come to the knowledge of Mr. Burbank that about 200 years ago there existed in France a plum known as the "Prune sans noyau." He succeeded in obtaining specimens of this fruit, but it proved to be of little or no commercial value owing to its poor quality. Its one valuable feature was its stonelessness, and Burbank set to work to transfer this character, by hybridization, to a variety of good quality. He succeeded, and there appears to be no reason why the stoneless character should not be similarly implanted upon all the different varieties of plums now in cultivation.

Similarly the "plumcots" are hybrids between plums and apricots, which Professor de Vries speaks of as "most delicious and beautiful fruits."

It must be admitted that Burbank's work is practical rather than scientific. He apparently pays no attention to the law of Mendel in his operations, and just goes on hybridizing until he gets what he wants. In this process enormous numbers of plants which do not fulfil his requirements have to be destroyed for every one that is worth preserving.

He is not necessarily concerned with the production of pure breeds; of forms, that is to say, which will breed true from seed, or in other words, of forms which will hand on their desirable qualities to future generations by heredity. This does not matter in the case of fruit trees and other plants which are propagated by buds independently of sexual reproduction. As a general rule, a fruit tree cannot be relied upon to come true from seed, the characters which it has received from different ancestors not being permanently combined, but separating out and undergoing fresh combinations in the sexual process, probably in accordance with Mendelian principles. The seedlings will therefore be "degenerate," as horticulturists say, and will no longer exhibit those valuable qualities which depend upon the confluence in one individual of several lines of ancestry.

The operations controlled so successfully by Luther Burbank are to a certain extent similar to those which take place in a state of nature. He produces a great variety of new forms and from these he selects what he requires. The process results in enormous waste, but so also does the process of natural selection. Under natural conditions waste of life is a necessary condition of progress.

The majority of Burbank's productions however, could not survive in a state of nature at all; they are essentially artificial and have to be artificially propagated by means of buds or cuttings. In this respect they are quite different from the pure races which it is possible to produce by hybridization carried out in accordance with Mendelian principles, in which new and permanent combinations of unit characters, capable of being transmitted by heredity, are effected.

Professor Bateson, Professor Biffen, Mr. Hurst and others have lately done much to demonstrate the possibilities of progress in this direction, and the value which the application of the Mendelian principles of heredity must have from the economic point of view. We know now that such cereals as wheat and barley obey the Mendelian laws of hybridization as regards various important characters. So also do horses as regards the colour of their coats, and human beings as regards the colour of their eyes, and in certain other respects. In short, it appears certain that Mendelian principles have a very general application, and the economic value of the knowledge of such principles in the case of organisms which are only propagated sexually must be enormous.

It is true that Professor Hugo de Vries considers that in the case of cereals it is quite unnecessary to resort to hybridization in order to effect improvements. He considers that all that is necessary is to select individual plants exhibiting the desired characteristics from amongst the numerous varieties which occur naturally, and to propagate by seed from them.

Speaking of the experiments in plant breeding which have been carried on with such remarkable success for many years past at the Swedish Experimental Farm at Svalof, he remarks:—

"They confirm the fact that the ordinary cultivated varieties of cereals are by no means pure, but must be considered as mixtures of well-defined types. Moreover, they show that these types are far more numerous than was previously supposed, and include hundreds of forms within each of the now prevailing sorts. . . . . The range of variability disclosed by these new studies is simply so wide that it affords all the required material for almost all the selections desirable at present, and will, no doubt, continue to be an inexhaustible source of improvements for a long succession of years. They are founded on the principle of single selections, and the range of application of this method is proved to be so extensive as to make all ideas of repeated or continuous selection

simply superfluous. It is even so rich in its productiveness that there is scarcely any room left for other methods of improvement, and especially should all endeavours of winning ameliorated varieties of cereals by means of hybridization simply be left out of consideration, as compared with the immense number of more easily produced novelties which this method affords."—"Plant Breeding," p. 50.

No doubt much can be done in this way, but it is obviously only applicable in the case of organisms which exhibit a very large number of naturally occurring true-breeding varieties or mutations, and such organisms are, I believe, comparatively uncommon. Moreover, it is difficult to believe that even in the case of cereals the possibilities of improvement can be exhausted by simple selection. Indeed Professor Biffen's work indicates a much wider prospect, for he has shown, for example, that susceptibility and insusceptibility to that destructive disease in wheat, known as "rust," behave as Mendelian characters, and that it is possible by a very simple process of hybridization to confer immunity from this disease upon naturally susceptible varieties.

It may be admitted that if you want a suit of clothes it is easier and more convenient to go into a slop shop and trust to chance for a ready-made article which will "do," but the results are hardly likely to be as satisfactory as if you chose your own cloth and then had it made up to suit your own requirements. Nature certainly supplies us with a fine choice of ready-made articles, but you may happen to want something that is not in the shop, and then it is a great thing to be able to select the best possible materials and have what you want made to order.

The great lesson which we have to learn from experiments in the breeding of plants and animals is that the living organism is a composite structure built up of a vast number of minute characters, many of which at any rate are separately represented in the germ-cells from which the organism develops. How this representation is effected we do not at present know, but the evidence points to the existence, probably in the chromative substance of the germ-cells, of ultra-microscopic material particles which are, in some way, responsible for the transmission of such characters from generation to generation. Moreover, it appears that each particular character of this kind may be either represented or not represented in any one germ-cell, and that in the process of shuffling which takes place in sexual reproduction individual characters may be added or subtracted, or substituted one for another, without affecting the stability of the organism as a whole. The practical importance of these results lies in the fact that it is possible by controlling the mating of male and female, and thus bringing about new combinations of selected characters, to control at the same time the course of evolution itself, and direct the stream of life in chosen channels.

Man's conquest of nature, which began with the control of inanimate forces and gradually spread over the animal and vegetable kingdoms, is now penetrating to the citadel of life itself. The citadel, however, has not yet capitulated. We have still much to learn; above all we want to know the cause of those sudden variations or mutations which occur in nature. We are already able to take advantage of such mutations for the improvement of plants and animals, but we cannot make our own building material; we do not know how such characters arise, and we cannot produce them ourselves.

It is easy, of course, to modify artificially the development of individuals, for individual development depends very largely upon the conditions of the environment,* but we have not yet learned how to render such modifications inheritable. In other words, our artificial modifications of the body seem to have no effect upon the constitution of the germ-cells.

This of course is the old problem of the inheritance of acquired characters, and from the nature of the case it appears extremely doubtful whether we shall ever be able to find a practical solution of this problem. Many people maintain that acquired characters cannot be transmitted at all; but it may be merely a question of the degree in which they are transmitted, and of the number of generations which it takes for a character acquired by the body to induce a corresponding impression upon the germ-cells.

The germ-cells are eminently conservative bodies, and thus it happens that while the individual organism is more or less susceptible to every change of environment, the race to which it belongs changes but slowly. This conservatism is itself doubtless an extremely valuable character, just as it is in human politics, where there is something to

* It has recently been shown, for example, to take an extreme case, that the addition of magnesium salts to the water in which the eggs of a fish (*Fundulus*) are developing will cause a large percentage of them to develop into Cyclopean monsters, with a single large median eye in place of the normal pair.

be said even for an hereditary House of Lords. It has probably arisen through natural selection, for while it is an advantage to the individual to be able to adapt itself to new conditions which may be as evanescent as its own brief life, it is still more important that the race to which the individual belongs should not be permanently influenced by every wind that blows, but should maintain an average adaptation to an average environment. Moreover, individuals which inherited accidental deformities or mutilations would be at a serious disadvantage in the struggle for existence, and thus the power of inheriting acquired characters must itself tend to be eliminated.

Even, however, if we are unable to bring about the hereditary transmission of acquired characters, there still remains a wide field open to us. We can not only select and cultivate favourable varieties with which nature provides us, but which might not, perhaps, survive in a state of nature; but we can produce at will new combinations of selected characters, and therefore actual new forms of life which might never have occurred in a state of nature at all.

The CHAIRMAN (Professor J. M. Thomson) said that on the occasion of special lectures, such as the Aldred Lecture, no discussion was invited, and it was therefore his duty, and at the same time his pleasure, to tender the hearty thanks of the meeting to Dr. Dendy for his most interesting lecture, though he regretted that someone more conversant with the special branch of science which had been so ably dealt with had not been able to occupy the chair on the present occasion. Sir William Ramsay had delivered a most brilliant lecture in the autumn of 1907, and they had heard that evening a second discourse of equally high merit. He was sure they might expect that the Aldred Lectures would in the future be just as brilliant and instructive.

EARNINGS AND HOURS OF LABOUR IN THE TEXTILE TRADES.

In 1906 an inquiry was instituted by the Board of Trade into earnings and hours of labour in all trades, and the first instalment of this inquiry, bearing on the earnings and hours of labour in the textile trades, has just been issued. A similar but less complete inquiry was carried out in 1886, and the principal object of the present one appears to be to show the movement in the twenty years 1886-1906. Unfortunately for the purposes of comparison, 1886 was a year of extreme depression, while 1906 was a year of exceptional prosperity. Sir H. Llewellyn Smith has sought to meet the difficulty by taking the quinquennial periods 1884-8, and 1904-8 to correct the results of the single year, but even this larger comparison is restricted to some extent by the fact that the earlier period covered four exceptionally bad years while the second period contained only one very bad year and two good ones including the exceptionally good one of 1907. The inquiry covers more ground than that of 1886 since in the earlier inquiry the principal object was to obtain the rates of wages for a full time week, whereas in the present one, to quote Mr. Askwith, "the main consideration was the ascertainment of the actual earnings of each individual irrespective of the hours worked."

Perhaps the most striking fact brought out by this return is the comparative decline in the numbers employed in the textile trades. Taking adults and half-timers the total in 1885 was 988,436, and in 1904—the latest date for which the figures are available—1,010,506. In the woollen and the worsted, the linen and the silk trades there were large decreases in all; having regard to the growth of population, there has been a serious falling off, with the exception of cotton in which the numbers increased from 479,073 to 514,204, and hosiery where they nearly doubled—from 19,374 to 36,305—owing to the extension of the factory system of manufacture in that branch, the present returns relating only to factories. It is a common statement that half-timers have greatly increased in recent years, but the present inquiry shows that between 1885 and 1904 they actually fell from 91,651 to 31,744, and in the cotton trade from 49,992 to 17,651.

In comparing the general average for full time workers deduced from the returns of 1886 and 1906 it must be remembered that many changes have taken place during the twenty years, and that the two years were very different in character. Textile processes have been considerably improved, new processes have been introduced, and the classes of goods manufactured have changed with fashion and standard of living. For all the textile industries combined the percentage increase in average full time earnings is shown to be 16 per cent. for men and 18 per cent. for women. The advance in the case of men was greatest in the cotton industry, in which it amounted to 22 per cent., in the case of women the increase was greatest in the jute industry, viz., 40 per cent.; in the cotton industry it was 24 per cent.; in the linen industry 21 per cent. The figures show very wide variations. In the cotton trade, for instance, mule spinners on full time average 41s. 2d. a week in all centres; in Bolton they rise to 45s. 9d.; in Manchester to 47s.; and in Liverpool to 47s. 6d. The earnings of weavers again range from 15s. 4d. for three-loom female weavers in Manchester, to 33s. 6d. for six-loom male weavers in Burnley. The average earnings of some of the men employed in the lace industry is noticeable. Of the lace-makers in the levers branch 33 per cent. earned £3 per week or more, and more than 80 per cent. earned £2 per

week or more. In the curtain and plain net branches the majority in both cases earned between 30s. and 50s. per week, the percentages below or above these amounts being comparatively small. The average earnings of the whole 8,360 workpeople in this industry covered by the returns was 21s. 11d.

In the period under review the maximum number of hours during which work can be carried on in the textile factories by women, young persons, or children was lowered from 56½ to 55½ on 1st of January, 1902, a reduction in the working time of nearly 2 per cent. Throughout the cotton, woollen and worsted, and carpet industries the regular working hours are practically identical with the maximum limit for textile factories. The average annual earnings of the workers were highest in the lace section, £54 10s., cotton coming next with £48. The inquiry shows that during the twenty years the position of the textile workers was materially improved both as regards wages and hours of labour. A comparison, so far as it is possible—and at best it must be very imperfect—between the earnings of British and German textile workers as obtained from this report, and that issued by the Board of Trade last year on Germany, shows that on the whole the German worker earns the larger wages.

BELGIAN HORSE BREEDING.

The horse fairs that are held in the course of the year throughout Belgium are now largely attended by foreigners, especially by Germans, who purchase, it is said, from 20,000 to 25,000 horses annually. In 1906, 53,500 horses were reported sold at an average price of £33. During the year 1907, 53,000 horses were imported into Belgium, principally from England, France, Holland, and Germany. It is estimated that there are at present some 275,000 horses in Belgium, and horse breeding has, thanks to judicious fostering on the part of the Government, become an important and remunerative industry. In 1907, 27,000 horses valued at about £1,500,000 were exported. The American Consul at Liége states that at the last horse show held in Brussels under the auspices of the Society "Le Cheval de Trait Belge," a remarkably interesting collection of animals was brought together, among which were found some of the best specimens of the equine race that are produced in Belgium. The exhibit of working horses at this show out-rivalled anything of the kind that had taken place in Belgium during recent years, and showed a marked advance over all previous exhibitions of this kind. Belgian horses may be generally divided into two distinct groups, the Flemish breed and what is known as the Ardennes horse. To the first group belong the large massive working horses in general use throughout the country, and found in especially large numbers in Flanders. These animals are largely sought after, both in the country itself and abroad. Under this class may also be included the Brabançon horse, which in appearance is almost identical with the Flemish animal, being equally large and massive. The horses of Hainaut, the Hesbaye, and the province of Namur, although belonging to the group of heavy working horses, represent in a measure the transition from the Flemish breed to that which inhabits the Condroz and Ardennes districts. Much smaller than the smallest Flemish horse, the Ardennes horse is robust, long necked, and broad shouldered; he resists fatigue and supports privations better than the horses of other races. Such at least are the characteristics of the pure blooded Ardennes horse, but this breed of late years, owing to its having been continually crossed, with a view of increasing the size of the animals, can scarcely be said to exist in its pure state any longer, and it is said to be somewhat difficult to find a really pure blooded Ardennes horse at the present time. The Condroz horse very closely resembles that of the Ardennes. Generally speaking the Belgian horse is being continually improved, and the Government authorities liberally encourage all improvement of the equine races of the country, placing their best bred stallions at the disposition of private breeders. Apart from the question of locality, the Belgian breeders are keenly alive to the importance of keeping in Belgium the best specimens of breeding stallions. These superior breeding animals are no longer put up for sale, as those who own them find it much more to their advantage to retain them, thereby giving the Belgian breeders a decided advantage over breeders of Belgian horses in other countries. As an illustration of the price of one of these high-class stallions, it may be mentioned that the owner of the winner of the world's championship at the Vincennes Exposition of 1900 refused an offer of £1,600 for the animal. Belgium has not been alone in her efforts to develop and improve the breed of heavy draft horses, as the French, Germans, and English have all made decided advances in the improvement of breeds of their Percherons, Boullonais, shires, and Clydesdales, as well as the Belgian breeds. The fact, however, that the Belgian horse is becoming more and more appreciated and sought after abroad can well be a matter of congratulation for the breeders in Belgium in their successful efforts to improve the race. The success of the Belgian horse in Germany, especially in the Rhine provinces, has ensured its adoption in other countries, and it is believed that before long this race will be universally preferred to all other heavy draft races; in France, an official stud book of Belgian horses has existed for the past two years. In Holland, this race is bred to the exclusion of nearly all others in the districts of Zeeland and Limbourg. In Italy, Hungary, Croatia, Russia, Denmark, &c., the Belgian horse is extensively purchased. In the United States, it has not met with the high favour that it has enjoyed in other countries. There among many

animals of this class, the Percheron has taken the lead, followed by the shires and Clydesdales; but during the last few years attention has been turned to the Belgian horse, and its popularity is on the increase.

THE MINERAL SPRINGS OF PALESTINE.

The Holy Land abounds in mineral springs, as for instance at Gadara (east of the Sea of Galilee), and at Hamamim Suliemani (east of the Dead Sea). Their temperature ranges between 80° and 140° Fahrenheit. Intensely saline springs exist along the banks of the Dead Sea, all cathartic and useful in the case of liver and other diseases. None of these waters are bottled or exported except as curiosities by tourists. Especially celebrated are the hot springs at Tiberias, which, even since the Roman occupation, have been renowned for their curative powers and in bygone ages were compared to the famous waters of Baia. According to the American Consul at Beirout, the present baths at Tiberias were built by Ibrahim Pasha in 1833 during the Egyptian invasion. Additions were made in 1890 by the Turkish Government, but the accommodation is inferior and lacks cleanliness. The temperature of these springs is about 143° Fahrenheit, and the waters contain sulphur, chloride of magnesium, and iron. They are in many respects similar to those of Carlsbad. The hot springs of Tiberias are largely frequented by natives from all parts of Syria, and are reputed to cure chronic rheumatism and various skin diseases. In 1887, Dr. Schumacher, of Haifa, was asked by the Turkish Government to plan suitable modern baths, but the project was never carried out, owing to the fact that, according to a firman, the baths could never be let for a longer period than two years, and consequently no responsible person could be found to take them over and place them under efficient management. All efforts by natives and foreigners to change the terms of the lease failed, the Government considering that the baths in their present state were quite sufficient for their purpose At present the revenues of the establishment accrue to Tiberias, while the annual rent, amounting to some £500, flows into the national exchequer. In Roman times the springs were called Ammaus. Pliny extolled their excellent properties. Roman villas, temples and baths, surrounded, and Herod's acropolis crowned, the heights near the Thermal baths. Under European or American management, with the expenditure of about £10,000, the establishment might, it is said, become a source of wealth to those concerned. The season lasts from February to May. In Galilee the climate is delightful in the spring, and according to the Consul, a resort offering such baths and such historical associations, would seem to have a bright future.

HOME INDUSTRIES.

The Budget and Home Industries.—Not since the great Budgets of Peel and Gladstone, which revolutionised the fiscal system of the country, have so many home industries been affected as by the Budget proposals now before Parliament. The interests concerned may be divided into three classes. (1) those which see their way to transfer the added burden to other shoulders, as, for instance, the brewers and distillers, and tobacco manufacturers: (2) those which hope to divert consumption from the threatened article to another, as from petrol to petroleum in the case of the motor industry; and (3) those which have to face the impost without hope of relief, as with the hospitals. Not only will "the Trade" shift the additional taxation from itself to the public; it is making large immediate profits. According to the Excise receipts, 2,000,000 gallons of spirits in excess of the average were taken out of bond by the Trade in April in anticipation of the increase of duty. The Treasury receipts show the extraordinary increase from £2,314,000 received in April, 1908, to £3,408,000 received last month, an increase of no less than £1,094,000. It is estimated that this "intelligent anticipation of events" will give the Trade a net gain of about £350,000, since each gallon escapes the 3s. 9d. additional tax. But this, of course, is only a part of the golden harvest being reaped just now by brewers and distillers: for they are charging the public a penny a glass extra on brandy, whiskey, &c., and proportionately on beer. What this means will be understood when it is remembered that a gallon of proof spirit, after being broken down, makes 150 glasses, so that the wholesale and retail traders between them will secure from the public 12s. 6d. a gallon, on 1,000,000 gallons more than they would have got if there had been no increase in the duty. In proposing to tax petrol, the Chancellor of the Exchequer encourages inventors to discover a suitable engine for self-propelled vehicles capable of running on heavy oils, with a high flash point. Petroleum engines of this type which work well have already been employed with complete success for marine purposes, and also as stationary engines on land, and although there are many difficulties in the way of using heavy oils in high speed engines of the ordinary construction, as applied to motors, it may be expected that the duty on petrol about to be imposed will, sooner or later, lead to increased use of petroleum for motor purposes. It is feared that the proposed tax of 1½d. per gallon upon petrol for use in commercial motor vehicles, which is equal to an increase of 25 per cent. on the fuel bill, will seriously handicap the country's internal transport. The hospitals unhappily come under the third class indicated above. They have already received letters from wholesale druggists intimating that owing to the advance in duty on spirits they will be compelled to charge increased prices, and an advance of 6s. 6d. a gallon on rectified spirits is spoken of, and of 10d. a pound on ether. It is estimated that in the

case of the London Hospital alone the increase in the cost of rectified spirits will mean nearly £100 per annum, and in ether of close upon £120. Taking the Metropolitan hospitals as a whole, it is expected that the Budget proposals, if they become law, will cause an increase of several thousand pounds per annum in their medicine bills.

The Tobacco Industry.—The imposition of an additional 8d. per lb. duty on tobacco took the Trade completely by surprise, and has seriously disorganised it. So far from expecting any such increase the Trade were not without hope that what is called the "war surtax" of 4d. per lb. would be removed. There is no precedent for raising the duty on unmanufactured tobacco so much as 8d. per lb. The 1900 addition, regarded as purely a war tax, was only 4d. per lb., bringing the duty up to 3s. per lb. On that occasion the trade refrained, owing no doubt largely to the inherent difficulties of doing so, from advancing prices to the consumer, but on the present occasion the consumer will have to bear the burden. The Trade is already readjusting prices. The working man's tobacco at 3d. per ounce, a feature of the trade for half a century or more, will disappear, and on tobacco and weight cigarettes the entire duty will be recovered by advancing the price to the consumer by a halfpenny per ounce. The change, as it affects cigars, is expected to be not in price but in size, which will be reduced, but the prices already fixed in the wholesale trade are mainly provisional. The alterations, as indicated above, do not take into account the great advance in the cost of raw material, and it is urged that advantage should be taken of this opportunity to advance prices to the consumer to a degree commensurate not only with the increase of duty but with the advance in the cost of raw material. Manufacturers expect that about a fifth more capital will now be required to carry on the same volume of business, and it is feared that this will have the effect of concentrating the manufacture of tobacco in the hands of two or three large companies, a tendency that has been very apparent for some years past. The additional cost of tobacco to the consumer must result in diminished consumption, and in the opinion of experts this decrease will be considerable.

The Shipbuilding Industry.—The past winter was the worst in the shipbuilding districts since 1898, and although the amount of new constructional work turned out of the yards, during the quarter ended March last was larger than might have been expected from the general condition of things, it was due, in considerable measure, to the fact that some vessels that, in ordinary circumstances would have been put into the water last year, were delayed, and so fell into the sum of this year's launches. But whilst there is no likelihood of a large accession of activity in the near future in the shipbuilding industry the outlook is improving. A large amount of new tonnage has been booked. The new orders reported as having been placed with the Scotch shipbuilders in 1909 are estimated to amount to a quarter of a million tons, and although they include Admiralty orders under the 1908 programme, the demand is mainly for merchant shipping, a large proportion of it being "tramp" tonnage. It is said, too, that the contracts are not on the long-credit system by which so many shipping co-partneries were brought into being, to the loss of most concerned, and which helped so largely toward the boom in shipbuilding in recent years; but are being entered into by level-headed men with the necessary capital at their back. Their idea seems to be to contract for ships at the present low prices, and to have them built leisurely, so as to be ready for the expected revival of trade next year. The amount of laid-up tonnage has decreased, and is decreasing, and the natural wastage of the world's merchant shipping through wrecking, break-ups, &c., is estimated at about 800,000 tons per annum, but of late so much tonnage has been unable to find remunerative employment that it is difficult to believe that any probable revival in trade will find work for all the new shipping now projected.

Insurance of Live Stock.—The dispute between the farmers and purchasers of live stock as to warranty continues, but it looks as if the farmers will succeed in resisting the demand of the butchers. There seems to be an opening here for insurance companies. Until now the large insurance companies do not seem to have laid themselves out for the business though insurance would appear to afford a solution to the difficulty, and the task of devising a workable scheme ought not to be beyond the ingenuity of the companies. Small local societies for the purpose of insurance have indeed been promoted already in certain districts but it would be much more satisfactory if the business were taken up by leading insurance companies.

Cotton-growing Within the Empire. — At the annual banquet of the British Cotton-growing Association a very encouraging report was given of the work done by the Association in assisting and directing the growth of cotton within the Empire. All are agreed as to the enormous importance of the work undertaken by the Association. Whilst Lancashire is dependent upon the United States to the extent it is at present for the raw material it requires for its cotton industry, it can never be sure that from one cause or another it will not have to face a repetition of the catastrophe of the early sixties, when the civil war in America stopped the supplies of cotton from the South. But it is to be feared that the time is still distant when territories within the Empire will render Lancashire independent of America. The revival of the cotton industry in the West Indies has been of much benefit to the natives in some of the islands, but the total exports remain very small; from Uganda, Nyassaland, and Rhodesia the reports are favourable, but the acreage under cotton cultivation grows only very slowly; it is from Nigeria that the largest imports may be expected. In 1903 Lagos

exported 500 bales, in 1907 the exports had increased to 9,700, last year the drought caused it to drop to 5,500 bales, but the produce of the first four months of the present year was 8,500 bales. The soil is suitable, the acreage practically unlimited, and labour is to be got at 6d. a day. It may, therefore, be hoped that in course of time Nigeria will supply a considerable proportion of our cotton imports, but it must be many years before the present dependence upon America is visibly diminished. The efforts of the British Cotton-growing Association to increase the growth of cotton within the British Empire deserve the thanks of the whole community, and it is pleasant to note how warmly their efforts are being seconded by the Colonial Office.

CORRESPONDENCE.

WEEVILS.

The *Journal* of the Royal Society of Arts of the 19th March, 1909, on p. 383, contains a paragraph referring to "Weevils," in reference to Mr. Frederick Nöel-Paton's article in the *Journal* of the 12th March, 1909, wherein the latter referred to investigations made which showed "that wheat uncontaminated with weevil before the experiment lost 26 per cent. of its weight in three months, after the introduction of the insects, while 65 per cent. of the kernels were at the end of that time found to be weevilled," all resulting in enormous damage and loss to all parties growing wheat, and as a natural result, retarding the progress of the country of production.

The following custom I have known to exist in Jamaica for over 20 years:—

Wholesale dealers in flour-meals, handling large quantities, or retailers who retail small quantities, handling wheat-flour, corn-meal, oat-meal, corn and such like, invariably have suspended near such stores a dried lobster. This is bought for a few pence from the fisher-folk, and is straightway suspended in proximity of these goods, say within 20 feet or so; and its presence effectually stops weevils from attacking such goods.

After reading the *Journal* article referred to it naturally came to my mind that perhaps the above is unknown outside Jamaica, and it is worthy of being brought before the Royal Society of Arts.

A. C. Bancroft.

Stokes Hall, Plantain Garden River,
St. Thomas ye East, Jamaica.
17 April, 1909.

[It is difficult to understand the reason for the practice described in Mr. Bancroft's letter, but the statement is given on his authority.—Ed.]

DEW-PONDS.

Under the above heading an article appears in the *Journal* of May 7th. This article is practically a reprint of a letter, signed "E. A. M.," which appeared in "Nature," on the 22nd April.

"E. A. M." in that letter attempted to controvert the views I expressed in my paper at the Royal Society of Arts on March 3rd.

I regret to say that the Editor of "Nature," could not spare the space to print my reply to "E. A. M.s" letter, but he forwarded my reply to "E. A. M.," for his remarks. "E. A. M.'s" printed criticism of my paper therefore remained unanswered, so far as the public was concerned; but now that his criticisms appear in the Royal Society of Arts *Journal*, another opportunity is afforded me of replying.

In my paper to the Royal Society of Arts, I attempted to explain those natural causes which compel the deposition of aqueous vapour into a dew-pond. So far as I know, the theory of the heat non-conducting properties of straw when used in the foundation of a dew-pond, had not previously been advanced, until my brother and I published "Neolithic Dew-ponds and Cattleways." Though the subject of dew-ponds was occasionally referred to by various writers, prior to the publication of "Neolithic Dew-ponds and Cattleways," I venture to think that it was this work which aroused the general interest of the public within the last few years.

"E. A. M.'s" conclusion that "the dew-pond of the Downs depends for its water chiefly upon rains, and in a much smaller degree on mists and hill fogs, and that dew, *per se*, forms a very inconsiderable factor in the supply," is no doubt in the main correct. The truth of this conclusion may at once be demonstrated by a comparison of the rainfall and the evaporation on the tops of the Downs. According to "Symon's Meteorological Magazine," April, 1909, it is stated that "On the summit of the South Downs the annual rainfall is from 35 to 40 inches; the annual evaporation is certainly not more than 20 inches, and so from rain alone a pond should accumulate a depth of 15 to 20 inches in a year, supposing the bottom is watertight."

Assuming the correctness of this statement, any watertight horse-pond on the tops of the South Downs in England, should year by year accumulate more and more water, until it overflows, even without any advantage which might be derived from a non-conductor heat in its formation.

The main point, however, to which I desired to direct attention in my paper at the Royal Society of Arts, was not so much how to obtain a water supply in this country but rather to show how a water supply might be obtained in a waterless country in the absence of rain, springs, or streams. Reference was made to the dew-ponds in this country, and I stated that "in numerous dew-ponds in this country the dew-point is reached without difficulty." To this remark "E. A. M." says: "Nothing is given in support of this statement, and we may well ask on what evi-

dence it is based. It presumably means that the water itself reaches a temperature which is below the dew-point." "E. A. M." is correct in that presumption, in so far as I am referring to the surface film of water.

The evidence that the dew-point is reached in some ponds in this country, is shown by the example I quoted from Mr. Allcroft's book entitled "Earthworks of England," where he states that from actual experiments "a dew-pond may rise as much as 2 inches in a single foggy night in January, and in five nights rise fully 8 inches. In the early summer the same pond collected 3½ inches of water upon five nights of heavy dew." The dew *per se* can hardly be considered as "a very inconsiderable factor in the supply" in this particular test, and I fail to see how this deposition could have taken place unless the surface of the water afforded a suitable condensing area.

If vegetation were growing above the surface of the water, or if the banks of the pond were covered with grass, the conditions would be altered; but these experiments were carried out by Mr. C. J. Cornish, and I am therefore unable to do more than quote from what has been already published by others.

If the dew was directly deposited on to the surface of the water, "E. A. M." may, I think, be satisfied that the temperature of that surface was below the dew-point, otherwise I cannot imagine that it would have formed a suitable condensing area.

The view expressed by Mr. E. A. Martin in a recent lecture on "Dew-ponds" given at the Royal Geographical Society, is "that dew can be received by a pond on its surface, even while a pond has not yet fallen to the dew-point."

This may be true so far as the temperature of the water below the surface is concerned. It is, however, the surface film of water that is alone involved, and what actually takes place here is not recordable by the readings on a thermometer. Careful scientific research may some day reveal what actually does take place when the aqueous vapour is condensed and when evaporation is in progress. We know in the rough that under given conditions certain results will be obtained, and by a scientific application of the principles, so far as they are known, a water supply may yet, I am confident, be obtained in certain waterless lands.

GEORGE HUBBARD.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

WAX FOR MODELLING PURPOSES.—I have a collection of bas-relief portraits in wax, some of which appear to be of considerable age. Can any member of our Society give me any information as to the earliest use of wax for modelling purposes?—CERA.

PORTLAND CEMENT AND LIME.—Can any member say what effect Portland cement has on lime mortar composed of coral lime or limestone lime? It is believed by some engineers and builders that the addition of Portland cement to lime mortar considerably weakens the composition, and that cement so used is wasted. I believe the addition of cement is beneficial, not only because it strengthens the mortar, but because it reduces the tendency of the growth of vegetation on walls, which in the tropics is very distructive.—J. L. S.

GENERAL NOTES.

HOOPER SCHOLARSHIP.—The Council of the Institute of British Carriage Manufacturers offer for competition the "Hooper" Scholarship of £50, tenable for one year at the Higher Technical Day Class for Road Carriage Building at The Polytechnic Carriage-Building Schools, The Polytechnic Annexe, Balderton-street, Oxford-street, London, W. Forms of application can be obtained by applying to the Secretary of the Institute, 1, Queen Victoria-street, London, E.C., to whom they must be returned on or before the 30th June, 1909.

PHYSICAL DEFECT AND THE WORKMEN'S COMPENSATION ACT.—It often happens, perhaps oftener than not, that an Act of Parliament intended to benefit a particular section of the community, inflicts upon it, or a portion of it, harm rather than benefit. This seems to be the case with the Workmen's Compensation Act. As a result of the working of the measure old and infirm workmen, and others tending that way, or suffering from physical defect, find it impossible to obtain employment. The insurance companies will not insure them, and employers will not take men they cannot insure. Thus the nation is

called upon to support workmen and their dependents whose means of subsistence has been withdrawn, and it is a matter of moment to devise some means to prevent the enforced pauperisation of those who are willing to support themselves and their families but are prevented from doing so by the action of Parliament. With this object a suggestion has been made by an insurance manager that seems worthy of consideration. It is proposed to enact that a workman who on account of age, physical defect, or infirmity, and consequent increased liability to accident, is refused employment, shall report himself to the medical referee of the district, to be appointed by the Government for the purpose, who shall, if he is satisfied with the circumstances disclosed, issue to the workmen a certificate, and an employer engaging such certificated workman shall be required to pay to the Government a per-centage on the workman's annual wages equal to that paid by the employer in respect of healthy workmen in the same grade of employment to the insurance company indemnifying him under the Workmen's Compensation Act. In the event of accident to the certificated workman compensation under that Act would be paid by the Government direct, and liability at Common Law and under the Employers' Liability Act would be suspended. In this way, it is thought, the *bona-fide* workman might escape the odium of pauperisation, and the nation secure a pecuniary gain approximating to the cost of the keep of the workman and his dependents under the Poor-law system, less the amount, if any, by which the compensation for accidents paid by the Government exceeded the premium paid by the employer.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evening, at 8 o'clock :—

MAY 19.—"Railway Development in China." By ARTHUR JOHN BARRY, M.Inst.C.E. SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

Wednesday afternoon, at 4 o'clock :—

MAY 26.—"The Manufacture of Nitrate of Lime from Atmospheric Nitrogen." By SAM EYDE. PROFESSOR SILVANUS P. THOMPSON, D.Sc., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock :—

MAY 18.—"Canada as a Field for British Investment." By J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada. The RT. HON. LORD HINDLIP will preside.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 17...British Architects, 9, Conduit-street, W., 8 p.m. Sir W. B. Richmond, "Smoke Abatement."

Victoria Institute, 12, Adelphi-terrace, W.C., 4½ p.m. The Very Rev. H. Wace, Dean of Canterbury, "Authority."

TUESDAY, MAY 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Colonial Section.) Mr. J. Obed Smith, "Canada as a Field for British Investment."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. J. Garstang, "The Hittites (Lecture I.), Monuments of Egypt and Asia Minor."

Statistical, 9, Adelphi-terrace, W.C., 5 p.m. Mr. R. H. Hooker, "The Meat Supply of the United Kingdom."

WEDNESDAY, MAY 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Arthur John Barry, "Railway Development in China."

Microscopical, 20, Hanover-square, W., at 8 p.m. 1. Messrs. E. Heron-Allen and Arthur Earland, "The Recent and Fossil Foraminifera of the Shore-sands of Selsey Bill, Sussex." (Part II.) 2. Mr. J. W. Gordon, "A New Illuminator for the Microscope."

Meteorological, 70, Victoria-street, S.W., 4½ p.m. 1. Colonel H. E. Rawson, "The Anticyclonic Belt of the Northern Hemisphere." 2. Mr. Albert Walter, "Errors of Estimation in Thermometric Observations."

THURSDAY, MAY 20...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. A. H. Salway, "The Action of Nitric Acid on the Ethers of Aromatic Hydroxyaldehydes." 2. Mr. G. Barger, "Isolation and Synthesis of P-hydroxyphenylethylamine, a Water-Soluble Active Principle of Ergot." 3. Messrs. A. W. Crossley and C. H. Hampshire, "Nitrodi-o-xylyl. (Nitrotetramethyldiphenyl). Preliminary Note." 4. Mr. F. D. Chattaway, "Ammonium Perhalides." 5. Messrs. A. McKenzie and H. B. P. Humphries, "Studies in Asymmetric Synthesis." (Part VIII.) "The Asymmetric Synthesis of 1-Mandelic Acid." 6. Messrs. W. H. Perkin and J. L. Simonsen, "Note on the Condensation of Acetone and Hippuric Acid." 7. Messrs. H. Hartley and W. H. Barrett, "Sodium Sulphite."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. G. Millais, "Newfoundland." (Lecture II.)

Historical, Lecture-hall, Field-court, Gray's-inn, W.C., 5 p.m. Prof. C. H. Firth, "Later Tudor Ballads."

Mining and Metallurgy, Geological Society's Rooms Burlington-house, W., 8 p.m.

FRIDAY, MAY 21...Royal Institution, Albemarle-street, W., 9 p.m. The Hon. Ivor Churchill Guest, "Afforestation."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7½ p.m.

SATURDAY, MAY 22...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. H. R. Rivers, "The Secret Societies of the Banks' Islands." (Lecture I.)

Journal of the Royal Society of Arts.

No. 2,948. VOL. LVII.

FRIDAY, MAY 21, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, MAY 26, 4 p.m. (Ordinary Meeting.) HERR SAM EYDE, of Christiania, Norway, "The Manufacture of Nitrates from the Atmosphere by the Electric Arc."

THURSDAY, MAY 27, 4.30 p.m. (Indian Section.) CECIL L. BURNS, Principal of the Bombay School of Art, "The Function of Schools of Art in India."

Further particulars of the Society's meetings will be found at the end of this number.

CHANGE OF HOUR OF ORDINARY MEETING.

The attention of members is drawn to the fact that the hour of the Ordinary Meeting on Wednesday, the 26th inst., has been changed to 4 p.m.

COLONIAL SECTION.

On Tuesday afternoon, May 18th, Mr. J. OBED SMITH, Assistant Superintendent of Emigration, Department of the Interior, Canada, read a paper on "Canada as a Field for British Investment and Settlement." The RIGHT HON. LORD HINDLIP presided.

The paper and discussion will be published in a subsequent number of the *Journal*.

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, June 29th, from 9 p.m. to 12.

The programme of the arrangements will be announced in a future number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

TWENTIETH ORDINARY MEETING.

Wednesday, May 19, 1909; SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Bader, Frederick Robert, Assoc.M.Inst.C.E., 57, Chancery-lane, W.C.
Blundell, Thomas George, 30, Ferncroft-avenue, Heath Drive, Hampstead, N.W.
Dickson, Archibald Allan Clifford, A.I.M.M., F.G.S., M.A.I.M.E., Rejoulie P.O., *vid* Nawadah, E.I.Rly., Gaya District, India.
Hay, Alexander Mackenzie, "The Statist," 51, Cannon-street, E.C., and "Marston," Warlingham, Surrey.

The following candidates were balloted for and duly elected members of the Society:—

Evans, Evan, A.M.I.E.E., Ryan-street, Stratford, Taranaki, New Zealand.
Lane, Frederick, Messrs. Lane and Macandrew, 26, Great St. Helens, E.C.
Mumm, Arnold Louis, 41 and 43, Maddox-street, Bond-street, W.
Perrott, William, B.Sc., Messrs. Johnson and Perrott, Ltd., Nelson-place, Cork, Ireland.

The paper read was—

RAILWAY DEVELOPMENT IN CHINA.

By ARTHUR JOHN BARRY, M.Inst.C.E.

Railway development in China, so far as the past is concerned, is merely a matter of history, but when it comes to considering its future prospects it is a subject which I confess I approach with much diffidence. Although I have just returnd from a visit to China, the object of which was entirely connected with railways, I do not feel that I have brought

back with me any very definite conclusions on the latter part of the subject. During the last ten years I have been closely connected with railway development in China, and, visiting the country as I do at short intervals, I may claim to have had favourable opportunities of watching the recent changes in the attitude of the Chinese towards railways. It has appeared to me that, from a frame of mind which led them to regard railways rather as a regrettable necessity, especially regrettable inasmuch as a measure of foreign assistance and control was necessary, the Chinese have gradually come to realise that the development of their railway system is a matter of prime importance to their country.

Later on I propose to return to the consideration of the condition of affairs with regard to railways which just now obtains in China; but to appreciate the various phases through which the attitude of the Chinese towards railways has passed, we must just glance at the history of the movement. This divides itself naturally into four periods.

The first period was marked by the attempt of the foreigners to induce the Chinese to permit them to introduce railways into the country, an attempt which failed before the fanatical and strenuous opposition of the governing classes.

In the second period we find an influential though comparatively small number of Chinese themselves borrowing the ideas of the foreigner, and succeeding, in face of much opposition, in bringing about the construction of the first railway in China.

During the third period, the Chinese having become more or less accustomed to railways, grasp the fact that they are necessary to the welfare of the country, and consent to the admission of capital for railway construction on mutually advantageous terms.

The fourth and present stage is characterised by a growing intolerance of foreign guidance and assistance, other than purely financial.

As regards the construction and management of railways, the Chinese are learning rapidly, but at present there are very few indeed capable of filling responsible positions which require men not only of very efficient technical education, but of experience as well. It must be many years yet before the supply of such men in China is equal to the demand.

Now this evening I will not attempt to refer in any detail to all the four stages of railway enterprise in China which I have mentioned. It would be absurd to attempt such a thing in the time available.

I propose just to touch on the first three stages very lightly, and it is the less necessary to do more than this because Mr. P. H. Kent has written a most interesting book which deals with them exhaustively, a book to which I would refer anyone who may desire to know more of the details of the past history of railway construction in China.

The fourth or present stage is the one which is of the more practical interest to us to-day, and what I propose to say on the earlier stages will be with the object of giving an idea of the principal obstacles in the way of railway developments in China which had to be surmounted before the present stage was reached.

It is more than 45 years since the first attempt was made to introduce railways into China.

In 1863 Sir Macdonald Stephenson paid a visit to China and drew up a comprehensive scheme for railway construction in that country. This scheme was presented by him to the Chinese Government, was received by them with that charming politeness for which the Chinese officials are noted; with equal politeness his document was placed in a pigeon-hole, and he himself with many expressions of esteem was bowed out of the country. If Sir Macdonald Stephenson were alive to-day, it would I imagine be some satisfaction to him to know that his scheme, or something very like it, is now being acted upon.

The next move emanated from Shanghai, the greatest and wealthiest foreign commercial centre in China. A proposal was put forward to construct a short railway from Shanghai to Woosung, about 12 miles down the Whang Poo river, beyond which point ocean-going steamers, owing to the existence of a bar, cannot pass without previously discharging much of their cargo. Permission to construct this short line was refused, but the subsequent application of Messrs. Jardine, Matheson and Co., the well-known Chinese house, to construct an ordinary road was sanctioned. When the road had been constructed, that is in the year 1875, Messrs. Jardine commenced to lay down upon it a 2 ft. 6 in. gauge railway. Under the late Mr. G. J. Morrison, as resident engineer, the work of construction proceeded smoothly, and when the first section of the line was opened, it was enthusiastically patronised by the Chinese, and promised to be entirely successful.

Notwithstanding all this, however, the project was doomed to ultimate failure.

One day, prompted, as many thought, by the officials, a coolie threw himself under the train and was killed. As a result of the commotion thus aroused and the subsequent inquiry the line was condemned and closed, purchased by the Chinese Government at cost price, and rails, sleepers, rolling stock, &c., were bundled out of the country. The credit, therefore, of building the first railway in China is due to Messrs. Jardine, Matheson and Co., and of being the first engineer to the late Mr. G. J. Morrison, who lived long enough to see the next project in which he interested himself, viz., the Shanghai-Nanking Railway, and in which he was associated with Sir John Wolfe-Barry and myself as consulting engineers, nearly completed. With the destruction of the first Woosung line ends what we may call the first stage of railway development in China.

Although Messrs. Jardine, Matheson and Co.'s efforts to introduce railways into China had been a failure they were destined to bear fruit ere long.

Amongst those who had seen the Woosung line in operation was a certain Chinese gentleman by name Tong Kin Sing, a near relative of H.E. Tang Shao Yi, who has just recently visited this country, and who in many ways resembles him.

The name of Tong Kin Sing deserves to be much better known than it is. He was a man of enlightened views, broad and liberal-minded, tenacious of purpose and public-spirited. He may perhaps be called the father of industrial enterprise on sound lines in China. Amongst other enterprises that Tong Kin Sing inaugurated was the first coal-mine to be worked on a large scale and on modern lines in China, and it was at his coal-mines at Tongshan in the north of China that the first step was taken which led to the construction of the first permanent railway in China. His first little railway was designed to bring coal from his pits to the head of a canal about seven miles distant. From this small beginning has grown up the most important railway system in China, about 600 miles in length, connecting Pekin with Mukden, the capital of Manchuria and the old home of the present reigning dynasty. It there joins up with the through route to Europe *viâ* Siberia.

Tong Kin Sing would never have been able by himself to bring about this great achievement; it might, in fact, never have been brought about had not Mr. Kinder been appointed engineer in charge of the construction of the tramway. Mr. Kinder is the most modest of men. I will not attempt to say all that justly might be said in praise of him. Difficulties that would to most men have been insuperable were to him merely obstacles that had either to be got over or to be got round. Facts are more eloquent than words, and the facts remain that he began by constructing a seven mile colliery tramway, and during 30 years of faithful service to the Chinese, under his fostering care, that seven mile tramway has developed into the great railway system I have just described.

Mr. Kinder has at last just resigned his position as chief engineer of the Imperial Railways of North China and returned to this country. If to Tong Kin Sing belongs the credit of initiating the first great railway in China, to Mr. Kinder, belongs the credit of creating it, thanks to the support he received from Li Hung Chang, the great viceroy and and the most powerful man of his time in China, to whose favourable notice he was introduced by M. Detring, the then Commissioner of Customs at Tientsin.

In the limits of this paper it is impossible even to mention all the vicissitudes through which the venture had to be conducted, or all the obstacles that had to be surmounted or circumvented. By dint of dogged pertinacity and skilful diplomacy the line was extended to Tongku, then to Tientsin, then to Pekin, then to the Great Wall, and finally to Mukden. Before this was done the fierce opposition of reactionary officials had to be faced as well as the superstitious antagonism of the people, "Fengshui" and the grave difficulties being chiefly responsible for the latter.

As one example of the former no sooner had Tong Kin Sing, backed by Li Hung Chang, obtained permission from Pekin to build his first seven miles of line than the permission was incontinently withdrawn. This was of course rather a severe blow, but he compromised matters by getting permission to make a tramway to be operated by mules. Whilst the formation was being constructed, Mr. Kinder started to work to build on the quiet a locomotive out of any odds and ends he could pick up. He got a boiler from an old portable engine, cylinders from another, wheels from a scrap heap, and the rest he built with native workmen in a shed behind locked doors. In the end he turned out a very serviceable locomotive. When at a suit-

able moment this was put on the line it was accepted by the Chinese as a *fait accompli*; and having become accustomed to it the Chinese Government raised no objection when it was replaced by locomotives from England. This engine, the Rocket of China, now stands in the fine new locomotive shops at Tongshan as a memento of the past.

If official opposition to railways is now merely a matter of history, popular superstition still exists, though in a modified form. Fengshui is still a power to be reckoned with, and interference with graves is still a difficulty. Fengshui is a geomantic mystery far beyond the scope of a mere Western intellect to grasp. The Fengshui of a place, a town, a village, or a building is, as nearly as I can express it, the luck of the place, but what that luck depends upon only the wise man skilled in the mystery can say, and some of the conclusions arrived at after solemn investigation by the sages of Fengshui would put to shame the pronouncements of the wizards of the middle ages. Spirits have to be taken into account and their accustomed movements only the wise man knows. He only therefore can tell you whether the line you have laid out, or the works you propose to construct, will interfere with the habits of the unseen world or not, and whether any, and if so what, modification must be introduced. You will appreciate, therefore, that Fengshui was, and to a decreasing extent still is, a potent and mysterious factor that has to be taken into account in railway construction in the Celestial Kingdom.

The grave question however is a simpler one. The Chinese are ancestor worshippers, and sad is the fate hereafter of one who permits the bones of his ancestors to be lost or scattered. To allow them to be disturbed at all used to be counted as a sin, but to-day the Chinaman of the lower middle and lower classes has arrived at the conviction that an ancestor will probably forgive him if the ancestral bones are reverently removed from their ancient resting-place and decently interred elsewhere. In all this there is very little difference between the Chinese and the European, but since the Chinese bury their dead on any piece of unoccupied ground, it is generally impossible to lay out a railway without interfering with graves. Nowadays this is no longer an insurmountable difficulty, for the business instincts of the Chinese have triumphed over superstition, if it may be so called, and his feelings may be salved by a suitable consideration. Any qualms of conscience that may assail him are dispelled by the knowledge that if his filial piety is expressed by sufficiently vehement conscientious objections, the amount of compensation he will receive will be proportionately higher. He must, however, be wise enough not to overdo it, for there are several sad cases, when in deference to the eloquent objections of living representatives of past generations, the centre line of a railway has been deviated, and no entreaty could bring it back again to where it was before.

The grave question in China has now become almost entirely a financial one, but it is still serious, for whenever compensation for disturbance is being paid it is remarkable how large a number of ancient and forgotten graves find owners. To make sure that a claimant really has a grave to claim upon, sometimes it is the rule to insist on each claimant producing the ancestral relics for inspection, and I know of one unfortunate man who was moved to genuine tears and despair, because after having done a brisk business in hiring out his parents' bones at 50 cents a time to eager applicants for compensation, one of them was careless enough to lose them, with the dire consequence to that enterprising representative of a family, that in the future world he would have no friend to welcome him.

But to return to what is now known as the Imperial Railway of North China. I have no time to touch upon the events which led to British capitalists becoming associated with the enterprise, nor can I describe the political difficulties to which the extensions of the railway gave rise, and the hostility of the Russians who saw in British energy asserting itself in Manchuria, a menace to their scheme of empire. I have no time even to explain the part played, during the Boxer rising, by the railway, or how England and Russia nearly came to blows about it when the rising was suppressed. How successful the railway is to-day, is evidenced by the fact that last year the total gross receipts amounted to about 11,000,000 taels, while the working expenses were only about 3,000,000 taels, showing a net profit of something like 8,000,000 taels, or say £1,000,000 sterling.

In 1894 war broke out between Japan and China; the close of the war marked the close of the second period of railway development in China and the commencement of the third. The disastrous result of the Chino-Japanese war was to China a profound surprise and humiliation. The foe whom she held in con-

tempt, had defeated her with ease, and if China's immense though untrained numbers, even if they had been available, might have altered the result of the war, want of means of rapid transport had prevented her from using them. Many of the more enlightened officials realised this, and grasped the fact that the remedy of the defect lay in the construction of railways.

There was no difficulty in obtaining the capital required for this purpose from abroad, for nearly every nation in Europe, as well as America, was willing and anxious to lend China the money she required on mutually advantageous terms, but at first it would appear that the Chinese Government cherished a hope that the capital required would be provided by her own people. That the necessary capital was not forthcoming in China is hardly surprising. The idea of private companies for the purpose of carrying out public enterprises did not appeal to the Chinese investor, and he had some reason in being shy, for the Chinese Government had shown an awkward way of taking over private companies after they became successful, and in a somewhat arbitrary manner taking them over at their own price.

Another feature of the situation at this time was that Russia, France, and Germany had each of them in view a definite programme of railway expansion in China, the objects of which were not merely the profitable investment of capital and the expansion of markets for their productions. Territorial extension under certain eventualities was perhaps an object of greater importance still. Russia was anxious, and reasonably anxious, to cut off an awkward corner that spoiled the alignment of her great Siberian Railway to Vladivostock, and take a short cut through Manchuria instead; an ice-free port in Eastern waters was also an object that Russia could not afford to lose sight of. Kiao Chau would, perhaps, be the best, but if not, Port Arthur and Talienwan had much in their favour.

Then, again, in the possible event of a partition of China, Russia could not regard with equanimity the prospect of Manchuria, Mongolia, Chili, and perhaps other provinces on the border of her Empire falling into the hands of any other power. For the moment, however, Manchuria was the principal object in view, and a policy of peaceful penetration was indicated.

France, on the other hand, had her interests in the south. Kwangtung, Kwangsi, and Yunnan all border on French Indo-China, and if Fate should decree a break-up of China, there was no doubt as to which pieces it behoved France to be ready to pick up. In the meantime it would be well to establish definite interests in these provinces, and at the same time railway communication between China and Cochin China would benefit the trade of the latter colony.

The idea of direct communication by railway with Russia, her ally now firmly established in the north of China, was also perhaps an object to be borne in mind.

The position of Germany was different: so far she had not got a definite footing in China, and with her rapidly expanding trade interests she very naturally determined that she was not going to be left behind when the time came, if it ever did come, for the division of the Chinese Empire. The province of Shangtung, with its valuable harbour at Kiao chau, seemed indicated as the natural object of German enterprise; and when the first opportunity presented itself Germany was ready and took it. In due time these various political aspirations took concrete form, and as a result the following railways came into being:—

First, the Russian railway, called the Eastern Chinese Railway, from the station on the Siberian railway called Manchoarie, through Tsitsihar and Harbin to Vladivostock, with a branch from Harbin to Yingkow, Port Arthur, and Talienwan.

Secondly, in the south, the French projected railway from Lao kai to Yunnan, which it is expected will be completed next year.

Thirdly, the German railway in Shantung between Kiao chau and Chinan Fu.

These railways came into existence in the following manner. It will be remembered that under the terms of the treaty negotiated by Li Hung Chang on behalf of China, which followed the Japanese war, China was compelled to cede, in addition to Formosa, Korea, Port Arthur, and Shantung. Under pressure from Russia, France, and Germany combined, Japan was forced to return these territories to China. Soon after this Li Hung Chang paid a visit to Europe, going first to Russia at the invitation of the Czar, to be present at his coronation. From that date Li Hung Chang became a firm friend of Russia. The first result of this was the agreement made between China and the Russo-Chinese Bank, a semi-official institution founded to promote Russian interests in the East. Under this the bank

acquired the right to form a company, in which only Russians and Chinese could hold shares, to construct a railway across Manchuria to form part of the through line to Vladivostock. This company was called the Eastern Chinese Railway Company and is of course a purely Russian company. It had unhampered control of the construction and working of the line, although the Chinese have the right to repurchase the railway in 36 years, and it is to revert to them absolutely in 80 years, by which time of course many things may have happened.

In 1898, under circumstances to which I will refer later, Germany occupied Kiao Chau, and obtained a 99 years lease of the port, whereupon Russia demanded and obtained a 25 years lease of Port Arthur and the Liao Tung Peninsula and a right to construct a branch from the Trans-Siberian Railway at Harbin to Port Arthur and Talien-wan. The Siberian Railway was opened throughout for traffic in 1901, after having taken only ten years to build, and anyone who has passed over that route at any time during the long Siberian winter, travelling day after day for eight days through a waste of snow with a temperature well below zero, must realise the difficulties that the Russians had to face in building that railway. To have completed successfully the building of 4,750 miles of railway under such conditions is a stupendous task, and to have carried it out successfully in so short a space of time as ten years is a record of which the Russians may justly be proud.

Since the Russo-Japanese war, the Eastern Chinese railway south of Kwangchengtsze has been converted to the 4 ft. 8½ in. from the Russian 5 ft. gauge. The Japanese have also a hastily constructed line from near Newchuang to the Yalu river. This railway they are now improving, and before very long probably passengers will be able to go by train from London to Fusan.

We will now consider the position of France in the south of China. In 1895, France obtained from China an acquiescence to her project of extending her railway system in Annam into Chinese territory. In 1898, Russia, Great Britain, and Germany, having been granted important railway rights in the north, by way of balancing up, China granted to France a lease of Kwangchauwan as a coaling station, and the right to construct a railway to Yunnan Fu.

The capital required for this undertaking was estimated at a little over £4,000,000. Of this sum £3,000,000 was raised on a joint guarantee of the Colonial and Republican Governments, the balance being subscribed half by a company and half by the Indo-Chinese Government. The total length of the line is 280 miles; eighty years after the date of completion the railway is to revert to China. Construction was commenced in 1903; some very heavy work in the deadly Namting Valley has been the cause of some delay and the loss of a great number of lives amongst the workmen. The railway will, however, be completed some time next year.

In 1898, the murder of a French missionary in the south led to a demand by France of concessions for further railways in the Kwangsi Province, but apparently nothing very definite was arranged.

We now come to the subject of the German railways in Shangtung.

The opportunity of putting into practice Germany's scheme for the expansion of her interests in China was afforded by the murder of two German missionaries in Shangtung. This occurred in 1897. Without delay the German Fleet in Chinese waters seized Kiao Chau Bay, and the German Government refused to evacuate it until her demands for compensation to the families of the murdered missionaries, the degradation of the Governor of Shangtung, and certain rights in Shangtung, were acceded to. After demur the Chinese Government acceded to these, but as Germany was not prepared to put any faith in Chinese promises, she insisted on occupying Kiao Chau until they were carried out. She further demanded a guarantee for the protection of the lives of German subjects in China in future.

The form this guarantee took was a lease for 99 years of Kiao Chau Bay and a portion of the province of Shangtung. At the same time Germany obtained the right to construct certain railways in that province. These railways were as follows:—A line from Tsing tau through Kiao Chau to Chinan Fu, a line from Kiao Chau to a point on the frontier of Kiangsu near the Grand Canal, and a line joining up the termination of these two railways.

These railways were to be constructed by a German company in which the Chinese were to be allowed to become shareholders if they chose. In 1899 the company was formed and commenced to construct the railway from Tsing tau to Chinan Fu. This line was opened for traffic in 1904, and is now a paying concern; it is about 240 miles long.

The German Government have spent a great deal of money at Tsing tau on the coast of the Kiao Chau Bay, and have created a very fine port there. When the railway between Chinan Fu and Tientsin is completed—it is now under construction, and will be referred to later—Tsing tau will become a serious competitor with Tientsin for North China trade, and still more so when the projected railways to put it in communication with Cheng ting and Kai feng are carried out.

The southern railway from Kiao Chau to the Kiangsu boundary has not been commenced as yet, but the third line running south from Chinan Fu is under construction as part of the Tientsin-Pukow Railway, for which an Anglo-German syndicate has found the money, and to which reference will be made later.

I have purposely grouped together the three railway systems just described, viz., the Russian, German and French, because the conditions which govern their inception and construction are entirely different from those other railways which came into existence, or, at any rate, were commenced during the third period of Chinese railway development.

This group of railways owes its origin to political rather than commercial aspirations. They are to all intents and purposes the property of the three countries named, and to them must now be added Japan, who is the proprietor of the South Manchurian Railway. China has little or no control over them; they are concessions in the true sense of the word.

In the case of the remaining railways, the sovereign rights of China are not impaired and although the instruments under which the capital has been raised are frequently called concessions, the word is a misnomer as applied to them. The loan agreements between the Chinese Government and the various syndicates concerned are all practically similar in principle. The Chinese Government borrows money at 5 per cent. interest; the syndicates are granted facilities and privileges which enable them to make sure that the money they lend shall be spent honestly and economically upon the object for which the loan is advanced. The loans are secured in the first instance by a mortgage on the railway itself, and in addition to the guaranteed 5 per cent. interest a small share in surplus profits is granted. The profits of the syndicate are represented by any difference there may be between the issue price and the price which the Chinese Government agree to take for each £100 bond, after deducting all preliminary expenses, cost of issue, underwriting, &c. In addition, the syndicates usually act as agents for the supply of material and are permitted to charge a commission on the cost.

In the supply of material, where possible, Chinese manufactures are to be preferred if of equal quality and price to those obtainable elsewhere, and next to those the manufactures of the country to which the syndicate belongs are to be given a preference.

Now the list of railways which belong to the third period, and for which the capital was raised on the general principles above named, is rather a long one, and I do not purpose to enter into any detail in connection with any except three, the circumstances connected with the initiation of which had a distinct influence on the progress of the general railway development.

The list of railways which belong to the third period is as follows:—(1) The Pekin-Hankow, (2) Hankow-Canton, (3) Pekin Syndicate Railway (bought by Chinese), (4) Cheng-ting-Fu-Taiyan-Fu Railway, (5) Kaifeng-Fu-Hsian-Fu Railway, (6) Pinghsiang-Chu chow, (7) Pekin-Kalgan (Chinese), (8) Swatow-Chauchau, (9) Macao-Canton, (10) Shanghai-Nanking.

Of these ten railways it is only necessary to refer at any length to three, viz., the Pekin-Hankow, the Hankow-Canton, and the Shanghai-Nanking.

I will just briefly mention the other seven lines.

(1) The Pekin Syndicate Railway.—90 miles long, was built by the Pekin Syndicate to convey coal from the mines when opened to a point on the Wei River, whence it was intended to convey coal to the market by boat. Since it has been completed the Chinese Government have bought it up: it does not pay.

(2) Chanting-Fu-Taiyuan-Fu Railway. — 160 miles long. A French syndicate took the line over from the Russo-Chinese Bank; metre gauge line; now completed. It should pay well.

(3) Kaifeng - Fu - Hsian - Fu Railway. -- Finished. The extension to Haian-Fu has yet to be built. The line is about 140 miles long, and is being constructed by a Belgian syndicate.

(4) Pinghsiang-Chuchow.—Built by European engineers with Chinese capital. It is 60 miles long and connects the Pinghsiang coal mines with the Hsiang-Kiang river.

(5) Swatow-Chao Chau-Fu.—A short railway, 30 miles long, built by Japanese engi-

neers for a Chinese, who made a very large fortune, as so many Chinese do, in the Straits Settlements.

(6) Macao-Canton Railway. — Being constructed by a company, half of whom are Portuguese and half Chinese; it is 130 miles long.

(7) Pekin-Kalgan Railway, 125 miles long; it is nearly completed, and is being built entirely under Chinese supervision out of the surplus profits of the Pekin-Tientsin Mukden Railway. There is some heavy work, including tunnels, at the Nankow Pass, where a gradient of 1 in 30, for 12 miles, has been introduced. Mr. Jeme Tien Yow is the chief engineer, and the way he has carried out this importaut work reflects great credit on him. He is the most capable Chinese engineer in China; he was educated in America, and gained his experience under Mr. Kinder.

We now come to the Pekin-Hankow Railway. In what has been called "the battle of the concessions," which took place soon after the close of the Chino-Japanese war, a very prominent position was taken up by Belgium. Russia, France, and Germany had each a definite policy in view, whilst Great Britain, who at the time considered herself as chiefly interested in the trade of the Yangtsze Valley, made it her business, so far as she could, to preserve the freedom of that trade unhampered by foreign interference. Belgium, on the other hand, had no special policy, except to find new markets for the products of her great iron industries and at the same time to do profitable financial business. On the other hand, she had no powerful army or navy with which unaided to ensure the respect of China. It was more or less necessary, therefore, for Belgium to attach herself to more powerful nations. France and Russia were indicated. Russia had been protesting against English activity in the north of China, and had come to an arrangement under which, in return for an undertaking on the part of Great Britain not to seek railway concessions north of the Great Wall, and not to place obstacles in the way of any enterprise there backed by Russia, the latter would give a similar undertaking with regard to the Yangtsze Valley. Russia could not, therefore, very well appear openly in the field in the Yangtsze Valley.

France, again, had her hands pretty full in the south of China and her relationship with Russia being so intimate, England might regard any special activity on her part in the Yangtsze Valley with some suspicion. Obviously, therefore, just as France and Russia could be very useful to Belgium, Belgium could be very useful to France and Russia.

It was at a time when this condition of affairs obtained that China proposed the construction of the Pekin-Hankow Railway. This was the first railway for the construction of which the Chinese Government invited the co-operation of foreign capitalists. After the Japanese war, the Chinese Government regarded the Pekin-Hankow Railway as a work of urgent necessity. Several attempts were made to raise the capital required by means of a Chinese company, but this of course failed. The Chinese then opened negotiations with an American group of financiers, who sent a party of American engineers along the proposed route to make a reconnaissance survey, but whilst negotiations with this group were in progress in Pekin, *i.e.*, in 1897, a Belgian syndicate appeared on the scene and underbid them, accepting practically all the terms offered by the Chinese without discussion. Having secured the concession, the Belgian syndicate found of course that it was unworkable, and with the help of diplomatic pressure, in which they were assisted by France and Russia, improved conditions were obtained. The appearance of France and Russia on the scene was considered by Great Britain as ominous, Russia having already established herself in the north and France in the south. If, through the Belgians, France or Russia, or both jointly, got control of the connecting link through Pekin to Hankow, and Hankow to Canton, there would be reason to fear that British interests in the Yangtsze Valley would be threatened. The Tsung-li-Yamen (in other words the Chinese Foreign Office, now called the Wai Wu Pu) assured the British Minister in Pekin that the concessionaires were a *bona fide* Belgian group, and had no political intentions. Information obtained by Dr. Morrison, the famous *Times* correspondent in Pekin, indicated that the statements by the Tsung-li-Yamen were opposed to facts, and the China Association in London urged the Government of the day to take steps to protect the British interests in the Yangtsze Valley that were then threatened. Sir Claude Macdonald in Pekin obtained a solemn assurance from the Tsung-li-Yamen that the Russo-Chinese Bank were in no way interested in the project, and immediately afterwards the agreement with the Belgians was signed. In the meantime, what purported to be a copy of the contract with the Belgians was published by

an English paper in China. So far the British Minister had not succeeded in being allowed to see a draft of the concession, but if the copy as published was correct, the statements made to him by the Tsung-li-Yamen were clearly untrue.

On inquiry, Sir Claude was informed by the Tsung-li-Yamen that the copy of the contract as published in the newspaper was incorrect, and an undertaking was given that no clauses admitting the Russo-Chinese Bank to participate in the project should receive Imperial sanction. Without further ceremony the contract was formally ratified.

As soon as this contract was published it became apparent that, notwithstanding the definite statements made by the Tsung-li-Yamen, the Russo-Chinese Bank were specially charged with all financial arrangements during the currency of the loan. Under the terms of the agreement the Belgian syndicate undertook to finance an issue of 5 per cent. bonds to the value of the equivalent in francs of £4,500,000 at 90 per cent. of their face value; the bonds were secured on the net receipts of the railway, and the interest was further guaranteed by the Chinese Government.

The syndicate had the right to direct the construction of the line, and for the supply of material Belgian manufacturers were to have preference. The syndicate also were to control the working of the line when completed, and were to receive 20 per cent. of the surplus receipts after the payment of expenses and interest on the bonds. The Chinese Government reserved the right to repay the loan at any time after 1907 and take over the railway. The loan was in any case to be repaid during a period of twenty years, commencing in 1909. It should be added that when the loan was issued four-fifths were subscribed for in France.

The length of the railway is 760 miles and serves a densely populated country. The cost of the line is supposed to have been about £5,000,000. After the Boxer rising the syndicate successfully claimed a sum of £960,000 as compensation for damage done to the works. The permanent way consists of 85 lb. rails laid on Japanese sleepers. These sleepers are cheap so far as first cost is concerned, but last a very short time. In several places the line has been washed away more than once during floods, but more bridges have been provided from time to time. The principal work on the railway is the great Yellow River bridge, nearly two miles long, consisting of 102 spans 65 and 98 feet in length. The piers consist of screw piles screwed about 36 feet into the extremely fine treacherous and bottomless silt of which the river bed consists. Each pier is protected from scour by pitching stone. Ordinary pitching is useless here as it rapidly goes out of sight or is carried down stream. Mattresses of rushes and brushwood are therefore laid round the piers and pitching stone is placed upon this, but to maintain the pitching is a constant war with nature. To take the trains across the bridge the heavy main line engines are cut off and light ones attached.

The railway earns large profits, although it does not pay so well as the Imperial railways of North China. I should add that last year the Hongkong Bank issued a Chinese Government loan in London for £5,000,000, secured on the provincial taxes of the provinces of Chikiang, Kiangsu, Hupeh and Chihli, and out of the proceeds of this loan the Chinese Government has just exercised its right of repurchase and has taken over the line.

We now come to the Hankow-Canton Railway, which may be regarded as a continuation of the Pekin-Hankow, and when constructed will complete the great north and south trunk line from Pekin to Canton and Hongkong.

When the Americans were compelled to retire from the negotiations for the construction of the Pekin-Hankow Railway in favour of the Belgians, they appear to have received a promise that the concession for the southern section from Hankow to Canton should be given them instead, and in 1898 a contract was signed between the Chinese Government and the American Development Company, of which Mr. Calvin Brice was president. Under this contract the American company agreed to provide the estimated sum required for construction, viz., about £4,000,000, for which amount the Chinese Government were to issue 5 per cent. gold bonds to a value which at 90 per cent. of their face value would produce that sum.

The Development Company were to construct the line, and were to be allowed 5 per cent. on the cost of construction except land and earthworks, as remuneration for general services. They were also entitled to 20 per cent. of the net profits of working after payment of interest and working expenses. The length of the railway is about 742 miles.

When, however, a careful survey of the route had been made it was found that the

cost of the line had been much under-estimated, and that £8,000,000 instead of £4,000,000 would be required. It became necessary therefore to negotiate a modification of the contract.

In these negotiations the Americans found themselves opposed by Belgium and France, but in the end they carried the day, and the terms of the contract were successfully adjusted. All now being ready to proceed with raising the capital, the Development Company invited the assistance of British capitalists. Most unfortunately, however, the South African war had broken out in the meantime, and no great amount of capital could be raised in London.

Another misfortune was the death of Senator Brice. No one appears to have been forthcoming to fill his place successfully, and as a consequence it was found hardly possible to raise the capital in America. This gave the Belgians an opportunity; they began to buy up the shares of the American Development Company, and soon gained the control of it. They appointed their own representative as President, and the American engineers in China were replaced by Belgians. This alarmed the Chinese, who had made it a condition of the loan agreement that the Americans should not transfer their rights to other nationalities. The Chinese authorities refused to accept Belgian control of the railway, and a keen dispute arose as to whether China had any right to object, seeing that the Development Company still remained an American company although the *personnel* was mainly Belgian. Russia's hands at that time being tied by the Russo-Japanese war, and the Japanese victories having taken their effect at Pekin, the Chinese Government remained firm. At this juncture Mr. Pierpont Morgan came forward, and shortly afterwards the Development Company was able to show that it was American once more in reality as well as in name.

Unfortunately this did not help on the construction of the railway; no more capital was forthcoming, and in 1905 an arrangement was made between China and the American company whereby the contract was cancelled, the Development Company receiving £1,350,000 compensation for work done and prospective profits. It was believed by the Chinese Government that this sum would soon be subscribed by the native gentry of the provinces affected, but again they were disappointed. The Government of the colony of Hongkong now came to the rescue, and lent the £1,100,000 (the balance required by China) at 4½ per cent. secured on the opium revenues of Honan, Hupeh, and Kwangtung. The loan is redeemable in ten years. The Chinese agreed that, if foreign capital should be required for the construction of the line, or for the projected Hankow-Chengtu Railway, British financiers should have the preference. The remaining history of the Hankow-Canton Railway belongs to the present day period of railway development, and will be referred to again.

The last railway belonging to the third period of Chinese railway development is the Shanghai-Nankin Railway, which was inaugurated under British auspices, as indeed are practically all those which we shall come to now in considering the fourth or present day period.

In 1898, Messrs. Jardine, Matheson and Co., in alliance with the Hongkong and Shanghai Bank, had applied to the Chinese Government for the right to construct, under conditions to be agreed, the Shanghai-Nanking Railway, and a preliminary agreement authorising the construction of the railway in question was signed early in that year. This agreement indicated the general conditions on which the railway was to be constructed, conditions practically the same as those granted for the Pekin-Hankow and Hankow-Canton Railways, and this agreement was to be followed by a more definite final contract.

The same group also applied for similar agreements for the construction of the following lines:—The Soochow-Hangchow-Ningpo Railway, Tientsin-Chinkiang Railway, Pukow-Sinyang Railway, and the Canton-Kowloon Railway.

In the same year, after what was looked upon as a breach of faith on the part of the Chinese Government, in connection with the signature of the contract with the Belgians, for the construction of the Pekin-Hankow Railway, to which I have already referred, the British Government insisted on the granting by China of the concessions applied for by Messrs. Jardine, Matheson and Co. and the Hongkong Bank.

To this demand the Chinese Government acceded, it being arranged that whatever form the final contract for the Shanghai-Nankin Railway might take the contracts for the remaining lines should be similar.

About this time Messrs. Jardine, Matheson and Co. and the Hongkong Bank formed a

combination with another group of leading British financiers, and the British and Chinese Corporation was founded.

The outbreak of the Boer war had made it for a time impossible to proceed with the construction of the Shanghai-Nankin Railway, but negotiations for the final agreement were set on foot. At the same time the British and Chinese Corporation had surveys made of all the other railways just mentioned. It was not until 1903 that these negotiations came to a successful issue and the final agreement for the construction of the Shanghai-Nankin Railway was signed and ratified by an Imperial decree.

The principal conditions of the agreement were as follows:—

The British and Chinese Corporation undertook to issue a loan for £3,250,000 at 90 secured by Imperial bonds, bearing interest at 5 per cent.

The bonds were secured by a mortgage on the railway and were in addition unconditionally guaranteed by the Chinese Government; the loan was to run for 50 years, but could be redeemed at 102½ after 12½ years, and at par after 25 years. The existing Woosung Railway was to be purchased for £125,000; land was to be provided free of charge, but the Corporation undertook to advance a sum of £250,000 to the Chinese Government to enable them to purchase the necessary land.

A board of five commissioners, of whom two were to be nominated by the Corporation, and two by the Chinese Government, were to be appointed, to take charge of the general direction and construction of the railway. The chief engineer was to be nominated by the Corporation and approved by the Chinese Government. He was to be *ex-officio* a member of the Board of Control. All other appointments were to be in the hands of this Board. For the construction of the railway, British manufactures at equal quality and prices were to have the preference over other foreign material.

In July, 1904, the first issue of £2,250,000 was made. The bonds were offered to the public at 97½. The issue was a moderate success, although the investing public did not by any means make a rush for it as they do now for Chinese loans on infinitely less favourable conditions.

A great deal of difficulty was experienced in getting possession of the necessary land at first. This was unfortunate, since it meant waste of money in the way of salaries to the staff, &c., and interest on the loan paid out of capital. When, however, a fair start could be made, the work of construction proceeded rapidly. The first section of the railway was opened to traffic to Naziang on November 20, 1905, and in the following July to Soochow and Wusieh; to Chan-chow on May 15th, 1907; to Chinkiang on October 15th, 1907; and on March 28th, 1908, the first train ran from Shanghai to Nanking.

Under the terms of the contract with the Chinese, it was stipulated that a first-class railway in accordance with the best modern system should be constructed. This has been done, and the Shanghai-Nanking Railway will compare favourably with any line in England or elsewhere, whilst there is no doubt it is the best found railway in China. The railway serves a wealthy district, the resident population of which are well off, and, as events have proved, quite appreciate comfort in travelling.

Between Shanghai and Soochow, for example, the railway runs parallel with the Soochow Creek, along which waterway numerous trains of passenger boats towed by steam used to pass daily each way. It used to be said that the railway would not be able to compete with these boats, but now, owing to the greater comfort and speed with which passengers by train are carried, these boats have been taken off, as the railway attracts all the passengers. The passenger traffic of the railway is extraordinarily heavy, and the liberal supply of passenger stock with which it has been provided is already being found insufficient to meet the requirements of this increasing traffic. As regards goods traffic, the railway has not as yet been so successful, the reason being that all goods carried by the railway have to pay far higher charges in the way of likin or inland revenue than goods carried in boats. The result of this is that, although the railway can carry goods more cheaply, safely, and quickly, the extra likin charges more than counterbalance these advantages. It is possible that in the end this difficulty will be adjusted, and if the likin charges on goods carried by railway are made the same as by water, I have no doubt that the goods traffic on the Shanghai-Nanking Railway will become as satisfactory as the passenger traffic is already. Attempts have been, and are being made, to get this anomaly removed, by Mr. Wong Ching Liang, the very able and enlightened Chinese managing director, and Mr. Pope, C.I.E., the general manager, but several

difficulties have to be surmounted, and some of these are complicated by the fact that likin collected on the railway belongs to the Imperial Government, whilst that collected on boat cargo is credited to provincial revenue.

If the Shanghai-Nanking Railway, however, is to be as successful as it ought to be, the Soochow-Hangchow-Ningpo Railway should, when completed, be worked with it as one system, as originally intended. The terminal station, the locomotive shops, &c., were all designed and constructed with this object in view. The charges for general direction and departmental offices ought to be charged against both railways, which together would comprise a system of 500 miles instead of only 200.

Unfortunately, the Chinese Government, under circumstances to be mentioned directly, have not adhered to the terms of their agreement with the British and Chinese Corporation for the construction of the Soochow-Hangchow-Ningpo Railway, and have handed over the construction and presumably the control of that railway when constructed, to a Chinese local company to which I shall refer later.

The terms granted in the case of the Shanghai-Nanking Railway loan mark the extreme concession that the Chinese Government will ever make to foreign bondholders. Such terms will never be repeated. Before the Shanghai-Nanking Railway loan was issued it was difficult to raise money in London for Chinese enterprises; at the present time, however, practically any Chinese 5 per cent. loan attracts a rush of investors to whom the Chinese Government's guarantee is everything, and the other conditions of the loan are of secondary importance. That the Chinese Government will always pay so long as they have the wherewithal to do so, is, I hold, fairly certain—if there is any question, it is, whether they will always be able to pay.

Conscious of the improvement in their credit, it was natural that the Chinese Government regretted having promised the same conditions for the other railways which are now under construction, as they had agreed to in the first instance for the Shanghai-Nanking Railway, and in the light of more recent experience in things Chinese it was not surprising perhaps that they refused to abide by the preliminary agreements and to sign the final agreements for these unless the terms were modified. It was also natural that in consequence of this attitude the negotiations for the final agreements for the loans for these later railways were protracted and troublesome.

The fourth period of railway construction in China I regard as commencing with the negotiations for the Canton-Kowloon Railway loan which was the first to be undertaken of the later railways to which I have just referred.

The second of these was the Tientsin-Pukow line, which is now under construction.

The third to be undertaken was the Shanghai Hanchow-Ningpo line, which now starts from Shanghai instead of Soochow as was originally intended.

The agreement for the Pookow-Sinyang line, the last of the railways for which preliminary agreements have been signed, has not yet been negotiated, and negotiations in this case are more difficult than ever.

In the case of the Canton-Kowloon Railway the Chinese insisted on the following modifications of the Shanghai-Nanking Railway terms. Instead of the railway being managed by a Board of Control on which the bondholders are represented, a Chinese managing-director was substituted, in whose hands the management of the railway is vested both before and after construction. Instead of the chief engineer being appointed by the representatives of the bondholders, he was to be nominated by them subject to the approval of the Chinese. Instead of the direction of the work of construction and the subsequent management of the railway being in the hands of the chief engineer, his functions on the Canton-Kowloon Railway are limited to those of adviser to the managing director, but it was agreed that no payments may be made from the loan funds except on requisitions countersigned by the chief engineer.

On the Shanghai-Nanking Railway the accountant was appointed by the Corporation, and all the accounts have to pass through his hands, he being responsible to the Board of Control. In the case of the Canton-Kowloon Railway the accountant was appointed on the recommendation of the representatives of the bondholders subject to the approval of the Chinese managing director, whose servant he is. His duties are to organise and supervise the accounts, and report thereon to the Viceroy through the managing director.

In the case of the Shanghai-Nanking Railway, the original bondholders had an interest in any surplus profits of the railway over 5 per cent.; in the case of the Canton-Kowloon Railway they have none. The issue price of the first Shanghai-Nanking Railway loan was $97\frac{1}{2}$ per cent.; that of the Canton-Kowloon Railway was 100 per cent. The Chinese re-

ceived 90 per cent. of the nominal value of the Shanghai-Nanking Railway loan, they received 94 per cent. in the case of the Canton-Kowloon Railway loan. The Shanghai-Nanking Railway loan was to run for fifty years—the Canton-Kowloon Railway for thirty years only. In both cases the railways are mortgaged as collateral security.

Notwithstanding these important modifications in the original conditions of the loan that have been introduced, the agreement has, in practice, been found satisfactory. The relationship between Mr. Wei Han, the Chinese managing director, and his British assistants, is excellent, and complete harmony based on mutual confidence and respect prevails.

The Canton-Kowloon Railway is a very important line, 100 miles in length. It starts at Canton, the great commercial centre of South China, and terminates at the frontier of the British leased territory of Kowloon by a junction with a very expensive and heavy section of railway 20 miles long that the Hongkong colony are constructing to complete the connection between Hongkong and Canton. In the future, if all goes well, by means of this railway Hongkong and Canton will be put in direct railway communication with Hankow, the future Clapham Junction of the great trunk lines of China, and thence with Pekin itself, so that before many years it should be possible to take a railway ticket at Victoria Station to Hongkong *viâ* Berlin, Moscow, Siberia, Pekin and Hankow.

The amount of the loan is £1,500,000, and although rather serious delays in getting possession of the necessary land have involved unnecessary expenditure, the railway is likely to be completed for the amount of the loan, or at any rate very nearly so.

When, after the signature of the final agreement for the construction of the Canton-Kowloon Railway negotiations were commenced in connection with the final agreement for the Tientsin-Pukow Railway loan, the Chinese Government demanded still further concessions from the financiers.

They agreed that the chief engineer should be an experienced European, but they insisted that he should be appointed by themselves, subject to reasonable approval, and that he should be under the orders of the Chinese managing director.

They would not consent to the appointment of a European accountant, and retain in their own hands complete control of the funds derived from the loan, subject only to the conditions that loan funds should be drawn upon on a requisition signed by the Chinese managing director, who is to certify for what the money is required. The bond-holders have the right to send a representative to examine the Chinese accounts at intervals.

The railway itself is not mortgaged as collateral security, as in the case of previous lines.

The amount of the loan was fixed at £5,000,000, the first issue being for £3,000,000 only, of which £1,890,000 was raised in Germany for the German section of the line 401 miles long, and £1,110,000 was raised in London for the construction of the British section, 235 miles long.

The total cost of the railway as estimated by German and British engineers for both sections was approximately £5,800,000, excluding interest payable during construction, which in this case is payable either from Chinese sources or from the proceeds of the loan at the pleasure of the Chinese Government, so that probably a further loan will have to be raised to complete the railway.

In England the loan was issued at 98¾ per cent., and was over-subscribed.

The principal work on this railway is a very important bridge over the Yellow River on the German section. It is too soon as yet to form a decided opinion as to the prospects of this railway. On the German section, at any rate, the work of construction is going on fairly smoothly. On the British section matters were not so satisfactory at first, but have, I believe, improved since. The Chinese methods of handling the loan funds gave cause for misgivings and complaint.

The last of the construction loans issued up to the present in this country is the Soochow-Hangchow-Ningpo Railway loan, the third of those for the construction of which a preliminary agreement was signed in October, 1898.

The Kiang Su and Chekiang provinces through which this railway runs are wealthy, and the local gentry are rich and enterprising. Fired with the laudable ambition to find the capital required for the building of railways in their own provinces out of their own pockets, the local gentry petitioned the central Government for permission to do so. Unfortunately the granting of the petition involved the cancelling of the agreement with British financiers that already existed. The central Government were thus placed in a serious predicament—they were afraid of refusing the

patriotic demands of the powerful provincial gentry on the one hand, and on the other, if they cancelled the concession they would lay themselves open to a charge of bad faith and give serious offence to the British Government. They appear to have thought that of the two courses open to them, the latter would follow the line of least resistance, but finding, as they did, their attempts to cancel the agreement aroused strenuous opposition, they next adopted an attitude of passive resistance to the settlement of the final agreement in order to gain time.

In the meantime two local Chinese Railway Companies were formed, the Chekiang Company and the Kiang Su, whose combined capital amounted to about £800,000, to construct the railway. These two companies were so ultra patriotic in principle that only Chinese were allowed to be shareholders, and no foreigner was to be employed by them. With £800,000 in their pockets, less than half what was required to complete the railway, they light-heartedly commenced to construct the railway on Chinese lines with Chinese engineers.

With regard to the qualifications of these engineers Dr. Morrison makes the following remarks in the *Times* of March 9th :—

"On the Kiang Su section the Chinese engineer in charge has only a rudimentary knowledge of railway construction; the engineer in charge of the Chekiang section is less incompetent, having been for one year at college in California. He is a son-in-law of the president of the company. One engineer in control of a section of twenty miles of railway has no engineering training, but owes his appointment to the fact that he was the favourite student of the president of the company, who is a well-known authority on the Analects of Confucius."

In face of this complicated state of affairs and with the additional obstacle of the antagonism of the local companies to face, it is not surprising that the British and Chinese Corporations found the negotiations for the final agreement difficult and tedious. At last, however, an agreement was arranged on the same lines as those of the Tientsin-Pukow Railway agreement already referred to, but interest during construction has to be paid from Chinese sources, and when in 1908 the loan was issued it was, like the previous one, over-subscribed in London.

When the Chinese Government signed the final agreement we must assume they intended to carry out its provisions, but that they have not done so is probably due to the fact that the local gentry have been too strong for them so far.

The money was lent to China on condition that the construction and control of the railway should be entirely vested in the Imperial Chinese Government; the local gentry have seen to it that the control is entirely vested in them. The Chinese Government appointed a managing director, but the local companies refuse to recognise him. The Chinese Government appointed, as they had agreed to do, a British chief engineer, but the local companies refuse to allow him to exercise his functions as chief engineer. The local companies having exhausted their own funds are now drawing upon the loan funds, and have done so in an irregular manner and contrary to the conditions of the loan agreement.

The class of railway that the companies are constructing is what might be expected under the circumstances. Dr. Morrison has fully described this in *The Times* already; it is unnecessary, therefore, to do so again now. From the point of view of an engineer the methods of construction adopted are often almost humorous, and as regards the supply of foreign material, it is perhaps hardly necessary to state that the clause of the loan contract which gives the British manufactures a preference has been honoured rather in the breach than in the observance.

So far as the bondholder is concerned, inasmuch as the Chinese Government have guaranteed his interest whether the railway pays or not, it does not perhaps much matter whether the money lent is being wasted, except that it is pretty certain that if the Chinese Government were to become responsible for many more railways of this kind they will find themselves unable to pay; I think, however, there is little doubt that the Chinese shareholders in the local companies may make up their minds to it that they have lost their money; in fact, I believe that many of them have made up their minds to this already.

The Chinese Government suffer most from this unfortunate state of affairs—not only the money for which they are responsible being wasted, but the principle of State ownership for all railways, so necessary for the best interest of China, is being violated; and lastly, but very far from least, the Chinese Government have been forced by uninformed and irresponsible provincial clamour into the position of having failed to uphold their reputation for reliability in the observance of their agree-

ments—a reputation so difficult to establish, so easy to lose.

In time, it is not impossible that the Chinese Government will regain control of this railway. They might have done so ere now had they not, in defiance of the agreement with the bondholders, made over the money lent to the local companies, and, if they do so, they may connect it with the Shanghai-Nanking Railway, and work the two railways together as one system, as was originally intended, and as ought to be done in the interests of the public and both railway systems; but much of the harm done in the meantime will be irreparable.

Although the last loan borrowed by the Chinese Government for railway construction was the Soochow-Hangchow-Ningpo Railway loan, they more recently borrowed, through the agency of the Hongkong and Shanghai Bank, £5,000,000 for general purposes, but more particularly for the purpose of repaying the Belgian loan of 1899 for the construction of the Pekin-Hankow Railway, and thus regaining full control of that railway. This was as usual borrowed at 5 per cent. interest guaranteed by the Chinese Government and was secured on the likin of the provinces of Chekiang, Kiangsu, Hupeh and Chihli.

Although the Chinese Government have now taken over the management of the Pekin-Hankow Railway they continue to employ expert European supervision where necessary, and the net receipts from that railway amount, I understand, to about £40,000 per annum, after having paid the interest on the loan.

The loan is repayable in thirty years, and the Chinese Government have already commenced to prepare for this by trying to raise in China a Government loan of 10,000,000 taels. The conditions of the proposed loan are very favourable—the interest guaranteed is 7 per cent.; bondholders are to share to the extent of 25 per cent. in the surplus receipts of the Pekin - Hankow Railway, and anyone who either subscribes himself or obtains subscriptions for large amounts is to be rewarded in money, or in money and official honours as well on a sliding scale according to the amount subscribed. So far there has been only a meagre response to this invitation, but whether the Chinese Government succeed or not in raising this internal loan it is difficult to appreciate the advantage they will gain by repaying a loan on which they have only to pay 5 per cent. with money raised on such far more onerous conditions.

Before concluding, the present condition of affairs in connection with the Hankow-Canton Railway calls for a few words. It will be remembered that the concession for the construction of this railway, the southern section of the great north to south trunk line of China, was originally granted to an American syndicate, who having done a certain amount of work, were bought out by the Chinese Government on terms mutually agreed between them, and that in order to get the money wherewith to pay off the American syndicate the Chinese Government borrowed from the Hongkong Government £1,100,000, an agreed condition being that in the event of it being found necessary to borrow capital from abroad for the construction of the Hankow-Canton Railway or the Hangkow-Chengtu Railway, British financiers should have the option of the business and British manufacturers the preference, on equal terms, for the supply of any materials ordered from abroad.

Before the American syndicate stopped work they had built in the neighbourhood of Canton a line of railway 30 miles long from Canton to the populous town of Samshui, and had also done a good deal of work on about 50 miles of the main line northwards from Canton. A local Chinese company was now formed at Canton to take over the work that had been done and to complete the main line northwards as far as the borders of the province of Kwantung, about 200 miles from Canton. The native company came into existence with great *éclat*; all sorts of promises were made to anyone patriotic enough to subscribe for shares, and a good deal of money was raised.

The Samshui line was taken over, and is being worked under Chinese supervision with an American traffic manager. For its length it carries an extraordinary passenger traffic which pays handsomely, but unless more is spent on maintenance, repairs, and renewals, it will hardly be able to maintain its record.

Construction of the main line northward was also taken in hand, and Mr. Wang, a Chinese engineer of ability and experience, was appointed chief engineer. Mr. Wang was educated in America, and had experience in railway construction under Mr. Kinder, on the Northern Railway. In the face of great difficulties inseparable from the conditions which govern the system of administration of Chinese railway companies, Mr. Wang is doing good work—ten miles have been entirely completed; on forty more the earthwork is complete and the rails laid; and the bridges are now being built. This portion of

the railway has been opened for traffic on temporary bridges whilst the permanent ones are being built Another seventy miles is under construction, but going on slowly, and the final survey is being made for the remaining length of railway, *i.e.*, to the northern border of the Kwangtung province. Whether sufficient money will be forthcoming locally to complete this railway, or whether it will have to be borrowed from abroad, remains to be seen. In the meantime, work in a desultory manner was taken in hand on the northern section of the main line, that is on about 500 miles that runs south from Hankow through the province of Hupeh and Hu-nan. Chang Chi Tung, the Viceroy, engaged a number of engineers, mostly Japanese, and seems to have hoped to build the railway somehow without having recourse to a foreign loan. Recently, however, it became obvious that if the railway was ever to be finished, money would have to be borrowed from abroad.

In the early part of this year, the Viceroy, Chang Chi Tung, invited the British and Chinese Corporation to advance £3,000,000 on what are now called the Tientsin-Pookow terms. These terms I have already described —they apply to both the Tientsin-Pookow Railway and also the Hangchow-Ningpo line.

Experience of these terms in the case of the latter line having been so unsatisfactory, and to a less degree in the case of the Tientsin-Pookow line, the British and Chinese Corporation, so far as they were concerned, were not prepared to accept them again, unless modifications were introduced which would give better assurance that the money to be advanced were properly spent on the work for which it was intended, and with due regard to economy.

A conference with Continental financiers was held, and it was understood that all were agreed that the modifications proposed by the British group were the minimum that it was safe to accept. In the meantime, the German group offered to accept Tientsin - Pookow terms. Chang Chi Tung therefore closed the bargain with them off-hand. His attention then was directed to the option he had promised when arranging the loan from the Hongkong Government.

There has been so much said and written lately, on this subject, that a compromise with the Germans and other nationalities concerned, appears to have been arrived at, which, at any rate, secures British interests so far as the Hankow-Canton Railway is concerned, even if at the expense of some of the recognised British interests in connection with the projected Hankow-Chengtu Railway. This compromise is perhaps likely to be hailed with chastened enthusiasm by a large number of people in this country, who are interested in China, but taking into consideration all the complicated and rather delicate circumstances of the case, it will probably be regarded by the majority as a reasonable solution of a difficult problem.

I have now come to the end of a very imperfect and superficial sketch of the history of the progress of railway development in China up to the present time. It is inevitably superficial, for I have attempted to condense the subject into as few words as possible, although I fear I have not escaped being tedious.

As to the future, I will not be guilty of the rashness of attempting to prophesy. We may, however, at least note the principal data upon which the problem of the future is based. It is certain that China is fully alive to the advantages of railways, and is now as anxious to build them as at first she was opposed to their construction.

That the Chinese railway system is in its infancy goes without saying. The railway system of India, for example, is only partially developed, but with a population of about 240,000,000 India can at least boast of about 30,000 miles of railway, whilst China, with a population greater by, perhaps, nearly 100,000,000, can at present show about 5,000 miles of railway only. Before Chinese railway development can compare with that of India another 30,000 miles or so will have to be built at a cost of, say, over £200,000,000 sterling.

Whether railways should be constructed by private enterprise in China, or whether the principle of State ownership should be universally adopted, is, perhaps, a matter of opinion. On this matter I think Mr. Kent puts it accurately when he says that State ownership is not only the best for China, but the only possible system compatible with success. Not only has experience so far demonstrated that Chinese railway companies are a mistake, but it would also be impossible to raise any large amount of capital by means of private companies in China. Private companies, too, would not have behind them the necessary power and authority which only the Government itself possesses. In private companies in China there would be too many private interests to be considered antagonistic to the interests of the undertaking and the Chinese

public. For these and many other reasons I think that the Chinese Government would do well to keep the construction of the railway system of the country in its own hands.

If the State is to take charge of the future development of the railway system of the Empire the question arises as to how they can raise the capital required. Can they raise it at home, and if not, can they raise it abroad?

There are many reasons why I think they cannot raise money in China. First and foremost money in China can command much higher interest than abroad. The Chinese capitalist regards 10 per cent. per annum as not a high rate of interest for a really safe investment, and gets his interest paid monthly. Sound native banks will borrow at this rate and lend it again themselves at anything up to 30 per cent., the maximum legal interest. It is hardly likely, therefore, that 5 per cent. railway bonds will appeal greatly to the Chinese capitalist; indeed, I much doubt whether the far more attractive terms that the Chinese Government are offering in the attempt they are now making to raise a loan of 10,000,000 taels, to which I referred before, will be successful in tempting the Chinese investor. There are other reasons as well, but I think the one I have mentioned is sufficient to prevent a Chinese Government 5 per cent. railway bond from ever being a popular investment in China itself, at any rate for many years to come. In several of the late loans, for example, subscriptions were invited in China as well as in England, yet, notwithstanding the fact that the Chinese Government guarantee had the additional advantage of being an undertaking to a foreign nation, no subscriptions were forthcoming in China.

The next question is, can China get the capital she requires from abroad? This is a question which could better be answered by a financier than by me, but I cannot help thinking she can on reasonable conditions.

It is true that the general financial position of China is being adversely criticised lately. I saw for example an article in the *Globe* on March 4th, in which it was stated that the foreign debt of China was £125,000,000 sterling, and that when the interest on this had been paid there only remained about £6,000,000 with which to meet the executive expenses of the Empire. If these figures are correct it is clear that China will have to find some new source of revenue before she can borrow much more money for railways. The railways themselves could be made to present the necessary source of revenue. I venture to believe that railways in China can be made to pay perhaps better than anywhere else in the world, but if railways are to be made to pay, first, all the money borrowed for them must be spent on the purpose for which it is borrowed and with due regard to economy and efficiency. Apropos of this it should be borne in mind that cheapness in first cost does not always mean economy. A flimsy railway not equal to the traffic it has to carry is not economical; cheap sleepers that have to be replaced every year or two are not economical; construction directed by inexperienced engineers is not economical, and a railway mismanaged when opened for traffic is the reverse of economical.

At present there are very few Chinese qualified railway officers. There are a certain number of able Chinese engineers no doubt—for example Mr. Jeme who built the Kalgan line, and Mr. Wang who is building the southern section of the Hankow-Canton Railway, but for many years to come there will not be enough men such as these to go round. In an engineer experience is even more important than theory, and reliable engineers take years to train.

There is little doubt, therefore, that for some time to come China will have to engage engineers from abroad to meet her requirements, and the same remarks apply to the senior officers of other railway departments. There is nothing derogatory to Chinese dignity in this. China has always been loyally served by the foreigners whom she has employed, and always will be. Their knowledge and experience in their own spheres have been, and will be, of the greatest benefit to her in every way; but if China is to be able to borrow the money she requires abroad, on the best terms, it will be necessary to cultivate the confidence of the foreign investor, a confidence which recent events have been calculated to shake.

What I venture to think is required is a strong and capable railway department or Board in Pekin, so constituted as to command the confidence of the foreign investor, and strong enough to command respect everywhere in China itself. The present Board of Communications falls short of this. Such a department would have its staff of expert assistants and inspectors, both Chinese and foreign, and would keep in touch with the administration of each railway, who would be responsible to the Board. The net earnings of all railways after payment of the cost of maintenance and renewals would

be paid to the Government Railway Department—the principles of its organisation might be somewhat similar to those of the Imperial Maritime Customs. A definite policy and a definite programme of railway construction should be laid down. To build up the revenues of the Board the best paying railways should be constructed first. The revenues and expenditure of the Board should be published. In time I think a Board so constituted would be able to raise loans on its general revenues, and pay off the various loans for the service of which the revenues of different existing railways are now hypothecated. To begin with, the Board ought to be able to show as revenue the surplus earnings of the Imperial railway of North China and of the Pekin-Hankow line, which (from information from Chinese sources, so far as the latter railway is concerned) amount, when taken together, to about £800,000.

DISCUSSION.

The CHAIRMAN (Sir John Wolfe-Barry, K.C.B.), in opening the discussion, said he was sure the audience would agree that in listening to the author, who was his nephew, and with whom he had been associated in much of his Chinese work, they had been listening to a man who knew his subject very thoroughly. It must be a great satisfaction to the Society that Mr. Barry had been able to attend and give such a detailed view of the great subject of railway communication in China, which all must recognise was one of the most important matters which lay before them in the future. The railway alone could effect the purpose of opening up of China to modern and western ideas It opened up an almost unknown land, and would affect the destinies of an enormous population and commerce. Still more profoundly would it modify the views of the Chinese themselves in respect to European ideas, and the views of Europe with regard to Chinese ideas; it would tend to bring Europe and China more and more together, greatly, he hoped, to the benefit of both. While stopping for a few minutes at a roadside station on the Great Eastern Railway in Essex the other day he was much struck by seeing on the wall a large advertisement saying, "You can take your ticket here, direct for Pekin and Japan *viâ* Harwich," a novel state of things which was somewhat startling to those who had not followed the development of Chinese railways. European interests were very large in the matter. First of all there were the financial interests represented by the great financial houses in London, Berlin, Paris and Brussels; there were also the interests of the bondholders, who were now putting very large sums of money into Chinese enterprises; and, lastly, it was necessary to consider the great importance of such matters to the manufacturing districts of the different countries which were interested in the development of China. In all those ways it must be realised that the various European nations were most keenly competitive; they were looking after the interests of their own nationalities; and he hoped that Great Britain would not be backward in taking their place in the financial ventures which were necessary for the development of China and of her manufactures. Looking to the future, as the author had pointed out, it seemed to be all important that no mistake should be made about the proper application of the money which the bondholders found. That was a matter which called for most careful attention, not only by the financial houses which brought out the loans, but also by the various Governments whose nationalities were interested in the great enterprises which lay before the coming generation. It must be clearly demonstrated that the money advanced was not wasted, but applied to enterprises which would be self-remunerative, and bring a safe return on the capital invested in them. While he looked at the subject to some extent from the inside, having been associated with many of the great undertakings to which the author had referred, he was also trying to take a more general view of the subject, and to point out how important it was that money that was put into Chinese industries should be carefully administered, for the good not merely of the bondholders, but of the Chinese themselves. Everyone wished to see China developed with railways in the same way that India had been developed, but he most cordially agreed with the author's remark that European control should be insisted upon as a guarantee, at least for many years to come. European control should not merely be exercised in the raising of money, but also in the application of it under responsible European technical advisers; and there should also be a board of management of all Chinese railways, similar to that which the Government of India had found it necessary to institute in that country. Under those circumstances he was persuaded there was a great future for Chinese railways. They ought, and could be made, to pay if properly and fairly constructed; and he thought it was possible to look forward to a great development in the future, which would be much more astonishing than that which had taken place within the last 15 or 20 years.

Mr. BYRON BRENAN, C.M.G., said the author had pointed out a great many mistakes which the Chinese had made; but it must be remembered also that mistakes had been made by the Europeans, who had been too much inclined to assume that the Chinese were keenly anxious to have railways, and that those who found the money, would be in a position to dictate their own terms. A different state of things was found when they came to put those assumptions into practice. A good many

the lines to which reference had been made would not be constructed within the lifetime of many present, but when they were, he thought the Chinese would be in a position to dictate the terms on which they would borrow the money; in fact the tendency was all that way at the present time, and the terms which were obtained from the Chinese eight years ago would never be obtained again. With regard to the desirability of having a Board of Management, it was possible it might come in time, but at the present moment the Chinese did not realise the necessity for it. He thought it would not be a bad thing to give the Chinese people plenty of rope, so that they would become thoroughly embarrassed in their financial arrangements, and then when they were in hopeless difficulties they might feel the necessity of reorganising the whole system. That might not come about immediately, but he believed before many years they would find great difficulty in paying the interest on their bonds out of the earnings of the railways; in fact, he doubted if a single railway was paying its way, excepting the Northern Railway from Tientsin to Pekin.

Mr. C. S. Addis said he had been particularly interested in Mr. Barry's *resumé* of the evolution of the demand for railways in China, which, he thought, formed part of a general quickening of the national life, and took its place along with the demand for education, Western luxury, and a development of the patriotic idea in the country. Yet, fired as the Chinese were by the national idea of China for the Chinese, they were unwilling to entrust the control of their railways to those with whose money they were constructed, and apparently equally averse from affording the necessary security. There was something pathetic in the way in which the Chinese Government of late had been scraping the national exchequer with a view to finding any source of security to offer instead of the railways themselves. It was just like the scene one was familiar with in China of the peasantry scraping the hills to find the necessary brushwood for their fires, and he was afraid, if allowed to go on, it would have the same result—China would be as denuded of credit as her hills were of trees. Mr. Brenan had suggested that perhaps the best cure for that was to give the country plenty of rope—to let her borrow as freely as she pleased, and give her as much control as she desired, until in course of time the ordinary financial drag would be applied, and she would find she could proceed no further. The objections to that plan, however, were so immediate, and it carried with it such a long delay in progress, that he believed the better course had been taken in coming to some sort of understanding, by which in future adequate guarantees would be given for the proper employment of the money. That seemed to him a good step in advance, and he thought that in itself was an augury which was fruitful of hope for the future. The next step which should be taken was, he thought, that the railways should be mortgaged as security to the foreign bondholder who, having paid the money, was entitled to some extent to call the tune. He was not without hope that that step also might be gained, and that when the independent sources of revenue became exhausted, or were required for other purposes, China might find there was nothing derogatory to the national dignity in pledging her railways in a way that was being repeatedly done by countries in the West. That might be assisted by the participation of Chinese subscribers in the railway loans. The author had alluded to one difficulty in that connection, namely, the much higher rate of interest which prevailed in China, but he did not regard that as a permanent feature. Interest was high in China because the security was bad, and as the security improved he believed, *pro tanto*, the level of interest would diminish. He associated himself with the author's remarks with regard to the *personnel* of the railway, and he believed it was one that no responsible financier would desire to combat; on the contrary, it was the desire of those connected with railways to encourage and assist China in every way in entering into her own inheritance. But as the author had insisted, the best way was to begin with a strong leaven at least of higher foreign officials, in the same way as in the Imperial Maritime Customs. Then, there was required a school of engineering, by which the Chinese would be gradually educated to take their proper place in the construction of the railways. With regard to the future, when one thought of the cumulative effect of the increase of inter-communication in China, the prevention of famine, and the improvement in social intercourse it would entail, one might look forward hopefully. The author at any rate, could look back with satisfaction upon his share in the work, and with confidence to the share which every one hoped he would take in it in the future.

Colonel E. St. C. Pemberton, R.E., thought some councils of perfection with regard to what was desirable had been given by previous speakers, very few of which would work out in the way hoped for. There was no doubt that the control of the railways was most desirable, but he agreed with Mr. Brenan that it was hardly likely that, in years to come, the Chinese Government would look favourably upon any efforts of other countries to secure control over the lines that might be built with foreign capital. It was a most advantageous circumstance that the solidarity of the European communities and financial interests in China had been recognised by the countries concerned, and that steps were being taken in Pekin to bring combined pressure on the Government to give more favourable terms as to guarantees of the loans. As long as that state of things existed there would be an amelioration in the terms, but it was doubtful in the future

whether the political condition of things in the metropolis of China would allow it to continue. He thought railways would be built more rapidly than many Europeans considered likely. The experience of the world during the last quarter of a century had shown that no country could be developed, certainly not rapidly, unless a network of railways was gradually spread over it. That had been shown to be the case in British Columbia and South Africa. The Chinese now had the experience of the rest of the world to go upon, and fully recognised the necessity of building railways. Those railways would rapidly be built, although it was another question whether they would be carried out to the entire satisfaction and advantage of the shareholders in European countries who enjoyed the guarantee of the Chinese Government. It would be a very singular thing if the railways in China did not pay, considering the many resources and huge population in the country. If the railways paid more, would be built, in fact they would be speedily built, whether they paid or not. The construction of the railways would react on the situation and development of the country, by means of the fact that the authority of the central Government at Pekin would be enormously increased and enhanced by the spread of the means of control; and with that increase of control the methods of construction of fresh lines and branches in the outlying districts would be put upon a better footing, because the provincial authorities would not be able to act as they had recently been doing at Shanghai on the Ningpo line. He had recently travelled through China for some months, and had come home feeling quite convinced in his own mind that there was a splendid future for the railways in that Empire. He hoped China would be able to construct her railways without getting into financial difficulties, and he thought that would probably be the case.

Mr. J. W. Jamieson said that the period of time covered by the paper was contemporary with his own service in China. He remembered the first line of railway, to which the author had referred, being put down and pulled up again, the waggons, rails, and engines being sent by steamer to Formosa, where they were dumped on the strand, and left to disappear in mother earth. The great railway development occurred just after the Chino-Japanese war, when he remembered the Director-General of Railways making several enquiries from him, as to who were the best people with whom to negotiate loans; and if Messrs. Jardine, Matheson and Co. had been a little more diplomatic, he thought they might have received the concessiom for the first railway, the Hankow-Pekin, which eventually went to the Belgians. Up to a certain point the railway development was quite satisfactory, but he thought the Chinese would have been well advised if they had given a substantial concession for a period of years on terms that would have been sufficiently tempting and remunerative to a sound foreign syndicate, and left it in their hands. If the Chinese had put their pride in their pockets, and trusted themselves in the hands of the foreigner, the railways would have been better constructed and better managed, and at the end of the period the Government would have obtained a sound going concern on reasonably equitable terms. In that way they would not have been called upon to handle the railways until they had been trained for the purpose, and were able to do justice to them. Unfortunately a new spirit had sprung up lately; and although he quite understood it and in a sense sympathised with it, he looked forward with considerable apprehension to what would happen in the future. He thought the Chinese had difficulties ahead of them for a good many years to come. He doubted whether, with the exception of the Northern Railway, a single railway was paying very much. No accounts had been published of the Pekin-Hankow Railway, with regard to which it was said two years ago that a profit had been made, but he recently read in a Chinese paper that, on the contrary, the Government had been called upon to make up a deficit. The Government was paying away money all round, and the income derived from it was not yet sufficient to meet the demands. The country was developing but slowly, and very careful nursing would be required to take it safely through the next ten or fifteen years. He did not wish to be in the least alarmist in his remarks, because he thought any railway in China which was properly located, would pay in the long run, although it would not pay 5 per cent. at the beginning. It was his opinion that the Chinese Government were going ahead at the present moment as fast as it was wise they should do.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Barry for his interesting and instructive paper, which Mr. Barry briefly acknowledged, and the meeting terminated.

WOMEN'S LIFE AND EMPLOYMENT.

In a paper read recently before the Royal Statistical Society, Miss B. L. Hutchins gave some interesting statistics of women's life and employment. At the census of 1901 women were 1,070,000 in excess of men, the ratio per 1,000 persons having steadily risen from 511 in 1841 to 516 in 1901. During the preceding decade the average duration of life was 44·13 for males and 47·77 for females, and the superiority of the female life had become more marked at each successive period since 1838. It appeared that, though physically weaker, women had a more tenacious hold on life than men. In the rural districts they were in excess from the age of [illegible] only, but in urban districts from the second year onwards. The number of boys born was somewhat

greater than that of girls; any reduction, therefore, in infant mortality automatically tended to increase the relative number of boys surviving. The healthier districts are thus helping to restore the balance, and to illustrate this point certain "unhealthy" and "healthy" counties were selected, showing that in the latter a higher proportion of boys survived.

How was this excess of female population provided for? Marriage was still the most extensively followed occupation of women, including over 5,700,000, or nearly half the female population over 15. Marriage might be supposed to provide for about three-fourths of women between the ages of 35 and 55. Before 35 and after 55 a large proportion were not thus provided for. The proportion of women and girls over 15 in 1901 returned as occupied was 34·5 per hundred living. The employment of single women was largely an episode of early life, girls' work being for the most part a "meanwhile employment." Woman was normally provided for by marriage for twenty or thirty years only, and this break in her life, and her return to competitive work in later life after a long interval, were among the chief causes of pauperism. The number of widowed, occupied or otherwise, was connected with the male death-rate. The toleration of preventable disease and accidents must create pauperism, and thus illustrated the saying that we could have as many paupers as we liked to pay for. Many more single women than married or widowed were returned as living on their own means, owing, no doubt, to the greater frequency of marriage among the poorer classes.

Details were given of the special conditions existing in Lancashire, where 38·7 per cent. of the women of all age over 10 were returned as employed. In Lancashire, 76 per cent. of the girls aged 15-20 were returned as against 65·9 for England and Wales. Between 20 and 25, the percentages were 64·9 as against 56·3. In Blackburn, 40 per cent. of the girls between 15 and 25 were occupied; and the demand for young girls' labour was increasing both in textile and non-textile work. 23·5 per cent. of women occupied in textiles were married or widowed. This fact was doubtless related to the high rate of infant mortality in Lancashire, but it was noted that the mortality of all ages for both men and women was much higher there than in England and Wales generally. A large part of the excess mortality was caused by respiratory and other diseases largely preventable, and due to unhealthy conditions of work or housing.

The number of women and girls returned as domestic servants in England and Wales was 1,285,000, of whom 35 per cent. were under 20. The German Empire, with a population of 56,000,000, contained fewer servants than England and Wales. Unfortunately, no material existed for estimating the number of women occupied with the care of children, whether as mothers or nurses.

Women were still the largest class of paupers, but in a decreasing proportion. Under the system of recording paupers by the year instead of by the day, the number of women receiving relief was smaller, both in London and in Lancashire, than the number of men. The figures for pauperism as a whole indicated that improved education and opportunity were rendering women more independent and self-reliant than formerly.

Women had a less task in industry than men, but beyond their industrial work, they often did an enormous amount of work at home, without outside help, in addition to the bearing and rearing of children. Considering these facts, and remembering also that the wife and mother was the first person of the household to feel the stress of want, the lower death-rate of women could not be explained as the result of privilege and protection.

BOOKS ON WATERMARKS.

NOT INCLUDED IN LIST PUBLISHED IN THE "JOURNAL," JANUARY 29TH, 1909.

(Compiled by Herr Hofrath Franz Bartsch.)

1862. Cohendy, M. Note sur la Papeterie D'Auvergne anter. à 1790 et les marques de fabrique des papeteries. Extr. des Mémoires de l'Académie de Clermont. 41 water-marks.

1882. Schiffmann, F. J. Die Wasserzeichen der datirten Münsterer-drucke als Zeugen für die Aechtheit eines undatirten. In Jahrbuch f. schweizerische Geschichte, Bd. 7. 9 water-marks.

1883. Geschichtsquellen der Provinz Sachsen Bd. XV. bearb. von Dr. Jacobs. 4 water-marks.

1888. Richard, J. M. Filigranes de papiers de la première moitié du XIV. siècle, conservés au Tresor des chartes d'Artois à Arras in Bulletin Archéologique du comité des travaux historiques. 54 water-marks.

1888. Secher, V. A. Fortegnelse over 235 Prover paa skiv papirsorter brugte af den Danske Admenistration fra den 15 til det 19 aarhundrede. 10 water-marks.

1889. Marabini, E. Die Wasserzeichen in Büttenpapieren des 14-19 Jahrhunderts. Alterthumsvereins München. 34 water-marks.

1889. Boudon, G. Notes sur quelques filigranes de papiers des XIV., XV. siècles et de la première moitié du XVI. Société des Antiquaires de Picardie. 37 water-marks.

1892. Briquet, C. M. Sur les papiers usités en siècle. Extr. Archivio storico Siciliano N.S. anno XVII. 41 water-marks.

1892. Les Caproni fabricants de Papier à la Serraz au XVII. et XVIII. siècle. Leur marques et filigranes par A. Perrin. 124 water-marks.

1896. Piekosinki Fr. Wybor znaków wodnych z XV. stulecia Estr. "Wiadomosici numizmatyczno-archologiczne." 1119 water-marks.

1897. I segni delle cartiere di colle di A. Lisini. Estr. Miscellanea storica della Valdelsa. 28 water-marks.

1897. Gautier, J. L'Industrie du papier dans les

hautes vallées franc-comtoises du XV. et XVIII. siècle. Extr. des Mémoires de la Société d' Emulation de Montbeliard.

1897. Bösch, Hans. Die Hohenzollern und die Papierfabrikation in Franken. Papierzietung, Berlin. 10 water-marks.

1897. Keinz, Friedr. Ueber die älteren Wasserzeichen des Papieres und ihre Untersuchung. Zeitschrift für Bücherfreunde. 11 water-marks.

1898. Briquet, C. M. Les Anciennes Papeteries du Duché de Bar. et quelques filigranes Barrois de la seconde moitié du XV. siècle. Extr. du Bibliographe moderne 1898. 8 water-marks.

1898. Devaulx, Th. Filigranes (marches de papier). Revue des arts decoratifs, Janvier. 28 water-marks.

1901. D. francesco de Bofaruly Sans. La heraldica en la filigrana del papel. 30 water-marks.

1903. Gollob, Ed. Verzeichniss der griechischen Handschriften in Oesterreich auszerhalb Wiens. Sitzungsberichte. der kais. Akademie der Wissenschaften in Wien phil. hist. Clas. 60 water-marks.

1905. Illig'sche Wasserzeichen aus Büdingen-Papierzeitung Berlin vol. 5. 7 water-marks.

1906. Moutailler, G. Memento des filigranes ou marques de papiers des 13, 14 et 15 siècles. Numerous water-marks.

1906. Würtembergische, Wasserzeichen. Papierzeitung Berlin H 100. 7 water-marks.

1906. Hössle, Friedr. v. Die Ulmer Papiermühle. Papierzeitung Berlin H. 102. 8 water-marks.

1907. Walter, C. F. Papierfabriken Flensburg. Wochenblatt für Papierfabrikation. Vol. 14. 3 water-marks.

1908. Hössle, Friedr. v. Die Papiermühlen im Bayrischen Allgaü. Wochenblatt für Papierfabrikation. Vol. 25. 116 water-marks.

1900. Hössle, Friedr. v. Geschichte der alten Papiermühlen im ehem. Stift Kempten und in der Reichstadt Kempten. Numerous water-marks.

1908. Szönyi, J. L. 14 szazadbeli papiros-oklevelеink vizjegye. (Marks on 14· cent. papers.) 223 water-marks.

THE REFRACTORY CLAY PRODUCTS INDUSTRY IN BELGIUM.

Refractory clay products are largely consumed in Belgium by the metallurgical industries, the glass works, the manufactures of porcelain, and in general all those industries where the work is carried on through the medium of heat at an especially high temperature. The manufacturer of refractory clay products utilises a special kind of earth of which there are large deposits in the neighbourhood of Liège, and in more limited quantities in the district lying between the Sambre and Meuse. The manufacture of refractory clay products has been subject to alternate periods of activity and depression, following to a great extent fluctuations in the glass and metallurgical industries. In 1899, a year of marked industrial prosperity, the manufacture of this class of products reached its maximum development. At the beginning of 1901 prices began to decline, and remained exceedingly low until 1904. For some years the situation has remained rather unsatisfactory for a certain number of factories not sustained by large amounts of capital. At the present time, however, in comparison with other industries of the country, that of the manufacture of refractory products is, it is asserted, in a fairly prosperous condition. The factories, as a general rule, are established near the deposits of plastic earth needed, and at the same time in as close proximity as possible to the centres of the coal-producing industries, while in many cases they are found in the vicinity of the metallurgical establishments, glass works, and other industries that utilise refractory products. The American Consul at Liège says that many factories are found in the province of Namur, at Andenne, Seilles, Floreffe, Wierde, and Florennes, and in the province of Hainault at Baudour, Hautrages, Sirault, Saint Ghislain, Stambruges, Chatelet Jumet, Roux, Marchienne au Pont, Marcinelle and Forges. There are other factories at Angleur and Ampsin. The refractory products most generally manufactured are bricks of the class known as "briques courants," other classes of brick and pieces of special construction and composition designed for various industrial uses, for the metallurgical industries, glass works and chemical industries. The manufacturers of refractory products, in reality, only furnish a part of those products utilised in the different industries. About one-third of the fire-clay products manufactured by those establishments that do not form an integral part of other industries, is exported. Among the exported products, those that figure most extensively are fire bricks for blast furnaces and glass works, gas retorts, &c. The principal countries to which the products of this industry are exported are England, France, Germany, Holland, Russia, Switzerland, Spain, Portugal, Italy, Brazil, the Argentine Republic and Mexico. Exports to Russia, which were of considerable magnitude some years ago, fell off to a large extent when a period of general industrial depression prevailed in that country, and they have been constantly decreasing ever since. Exports to France steadily decreased up to the year 1905, owing in part to the import duties and the creation by Belgian capitalists of three factories for the manufacture of refractory products in the north of France. The industry of the extraction of refractory clay in the basin of Andenne and Bandour is an industry which has continued to exist under most prosperous conditions. Besides the exports of plastic clay, Belgium furnishes dolomite and lime for a great number of the steel works of Rhenish Prussia, the Grand Duchy of Luxembourg, Lorraine, and the north of France.

HOME INDUSTRIES.

The Meat Supply.—The Report of the Departmental Committee appointed to inquire into combinations in the meat trade shows, *inter alia*, that the dependence of the United Kingdom on foreign supplies, although it has tended to increase in recent years, has not done so very rapidly. In 1898-9, the home supplies were 55·0 per cent. of the total supplies; in 1907-8 they were 54·0 per cent. The percentage of beef and veal fell from 63·3 to 60·8, and of mutton and lamb from 61·2 to 55·9, but the percentage of pig meat rose from 38·1 to 43·1. But the proportion of home to foreign meat varies very widely in different markets. For example, at Dundee, Newcastle, and Norwich, almost the whole of the supply comes from home sources. On the other hand, a large part of the meat supply of Glasgow is drawn from abroad; about two-thirds of the meat which comes into Manchester is of foreign origin, and at Smithfield it reaches no less than 80 per cent. Only 1 lb. in 5 lbs. of the meat sold in that market is home-grown. Taking the last decade, the average annual amount of the supplies of home-grown meat was 25,035,000 cwts., the maximum being 26,063,000 cwts. in 1899-1900, and the minimum 23,705,000 in the preceding year, the amount for 1907-8 being 25,313,000 cwts., or rather above the average for the previous nine years. The increased demand, due to the growth of population, and an advance in the standard of consumption, has been met by a rising importation. The importation of live animals has, except in the case of cattle, almost disappeared, and in the last three years the importation of cattle has tended to diminish. The imports of chilled and foreign beef, on the other hand, have increased very largely, although for the four years, 1905-8, they show but little change. American beef is chilled, and so is a large and increasing part of that from the Argentine, but the distance from Australasia to the United Kingdom renders recourse to freezing necessary. The best American chilled beef has commanded a higher price than the best English beef, and than some qualities of Scotch beef; Argentine chilled beef ranks lower but great efforts are being made by Argentine cattle-rearers to improve their stock. The most striking feature in connection with the meat imports of recent years is, perhaps, the rapid advance made by the Argentine Republic, and the fact that in the last four years it has taken the place of the United States as the principal source of supply. The supply from the United States is likely to diminish owing to the growing home demand.

British Ports Expansion.—The new port authority for London is now well under weigh and it may be expected that vigorous steps will be taken to ensure the maintenance of that Port supremacy enjoyed by Londoners for many generations. In recent years there has been unprecedented development of harbour accommodation, and in some respects provincial ports show greater improvement than the Thames. The first want of the modern port is depth of water. The length and breadth of ships have been extended much more than increase in depth but deeper draught is not to be avoided. The importance of this to the Atlantic liner will be understood when it is remembered that on an average draught a liner of 23,000 tons can carry only from 500 to 600 tons of cargo, whereas an increase of one foot in her draught would enable her to carry 1,600 tons, and a two feet increase 2,500 tons, with very little loss in speed. At Southampton the entrance channel to the port has been deepened to a depth of 35 feet, and there are graving-docks over 850 feet long, 88 feet wide, and with entrances of 80 feet breadth, besides other smaller docks and shipways. At Bristol the Royal Avonmouth Dock was constructed at a cost of £3,500,000; Cardiff followed suit with the Queen Alexandra Dock, and in October the Swansea Harbour Trustees expect to open one of the largest docks yet built, with an area of 60 acres, and Port Talbot, Newport, and Barry near by are active in providing new facilities for shipping. The whole of the dock system on both sides of the Mersey has been revised, and the Mersey Docks and Harbour Board have a £3,000,000 scheme in hand, while at Garston a large dock has just been opened. At the Hartlepools, Blyth, and Middlesbrough dock accommodation has developed immensely, and the Tyne Improvement Commissioners are untiring in improving the port of Newcastle. Nor is Scotland behindhand, for great works have been and are being constructed for deepening the Clyde channel, and there are now over 220 acres of water space at Glasgow where vessels drawing over 30 feet of water can be accommodated.

The Small Holdings Act.—Wherever the fault may be, it must be admitted that, notwithstanding very numerous applications, the number of small holdings actually created under the Act is very low, being only about 4 per cent. of the approved applications. It must, of course, be remembered that the Act has been in operation for little more than sixteen months, and that the first six months were really a period of preparation and investigation. It must be admitted, too, that the rate of progress is quickening. In the first six months 23,000 applications for small holdings were received, but only 1,406 acres were acquired, and only one compulsory order was made. In the second six months 17,090 acres were acquired and eleven compulsory orders were made. During the first four months of the present year 11,754 acres were acquired, and forty-one compulsory orders were applied for, so that as time goes on the amount of land acquired for the purpose of small holdings is growing. But even at the present accelerated rate many years must elapse before any great change can be effected in the ownership of the land. And it is difficult to avoid the conclusion that the local authority is in some counties much less sympathetic than it might be

For example, in the recent debate in the House of Commons it was officially admitted that in Surrey only 10 acres have been acquired, in Sussex five, and in Cardigan and Flintshire none. Yet in Surrey there had been 114 applicants, of whom 56 had been approved; in Cardigan there were 129 approved applicants, and 2,096 acres asked for; and in Flintshire 1,400 acres had been applied for. Clearly some county councils are sluggish in the matter, and there is ground for thinking that the requirements of the Board of Agriculture in regard to the share capital of co-operative societies for the acquisition of small holdings are over rigid.

The Sweated Industries Bill.—It is satisfactory to find that among the larger manufacturers of ready-made garments there is a general disposition to welcome the Sweated Industries Bill. They say that smaller rivals, with inferior productive facilities, seek to reduce their cost by cutting down wages, whilst the wage-sheets of leading producers show that the sweating evil does not accompany minimum cost of production, but often connotes waste and incompetency in productive methods. As to State interference raising the cost of production and inducing the importation of cheap foreign goods, it is pointed out that the British exports of "apparel" have of late years approximated in value to £6,000,000 per annum, exclusive of hats and bonnets. But it would be unwise to expect very much from the mere enforcement of a minimum wage. It may well prove in many cases the transforming of the woman into the main supporter of the family, leaving the man to accept even worse pay or more casual conditions. Moreover, if the principle of the living wage means anything, it means not only a minimum wage but also a minimum continuity of employment. Of what avails it that the worker gets a better rate per hour unless the average number of hours per week and weeks in a year, is maintained at a certain level?

CORRESPONDENCE.

DEW-PONDS.

In the issue of *Nature* of the 13th inst., Mr. J. B. Cohen writes under the above heading saying that he has always been sceptical about the theory of dew-ponds since my brother and I published "Neolithic Dew-ponds and Cattleways."

Mr. Cohen's experience is "that lakes and ponds lose their heat slowly, and that after radiation has set in at night they indicate a much higher temperature than the ground adjoining, or the air above." And in proof of this Mr. Cohen observes that "on Coniston Lake in summer, after a night of heavy dew, the bottoms of the boats inside were perfectly dry, whilst the gunwale was covered with moisture, showing that the portion of the boat in contact with the water had been raised in temperature above the dew-point."

Mr. Cohen has also found that the temperature of the water of a dew-pond is above the temperature of the air. "It is impossible, therefore," he says, "that dew could deposit on the ponds under these conditions."

Mr. Cohen, like Mr. E. A. Martin, seems to be satisfied by taking the comparative temperatures of the water and the air. I may repeat that I have before attempted to explain, that it is not the temperature of the bulk of the water that, in my opinion, regulates the deposition of dew, it is the temperature of the surface film of water which is alone involved, and this is not readable on the scale of an ordinary thermometer.

The results obtained by Mr. Cohen and Mr. Martin appear to me to be on this account purely negative.

"E. A. M." is quoted as pointing out "that it is inconceivable that the clay or straw in a full dew-pond can have much connection with the temperature of the water." I do not know to what "much connection" may amount, but from my own experiments with a non-conductor of heat, it makes all the difference between the presence or absence of dew deposition. This was curiously exemplified in a pond constructed by my brother and myself, where we used square slabs of waste mica. The slabs were two feet square and two inches thick. The upper surface of the slabs after they were laid was coated with a uniform layer of asphalte. The asphalte ran in between the edges of the mica blocks, so that the seams of mica were disconnected from each other by a thickness of about ¾ inch of asphalte. When the hoar frost lay upon the ground a curious spectacle presented itself. On the upper surface of the coating of asphalte the hoar frost was deposited in squares precisely corresponding to the area of the square mica slabs below. The surface of the asphalte lying above the joints showed no signs of hoar frost and remained black. The pond in fact presented the appearance of a beautiful chess-board with all white squares and black lines between them. This experiment was a very striking example of the effects of a good non-conductor of heat when used in the construction of a dew-pond. GEORGE HUBBARD.

112, Fenchurch-street, E.C.
19 May, 1909.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name

and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

Cacao Beetle.—Can any member inform me as to the best means of exterminating the cacao beetle? —Planter.

Gourds as Wild Duck Decoys.—I have seen it stated that the natives of Venezuela employ gourds as wild duck decoys. Where can I find a description of the manner in which they are used?—W. M.

ANSWERS.

Portland Cement and Lime.—I can say from experience that the following mixture will make a hard plaster for internal walls of public buildings, or where a hard plaster is required: ½ cubic yard of putty lime, ½ cubic yard of sharp sand, 1 bag (2 cwt.) of Portland cement. Portland cement is used instead of Plaster of Paris for gauged work in some parts of the country, the putty being made from burnt limestone. If too much Portland cement be used the plaster will crack.—John S. Chenhall.

Wax for Modelling Purposes. — Bees'-wax has been used for modelling purposes for at least 4,000 years; but specimens of so great an age are naturally rare. In the Berlin Museum of Antiquities, however, there are several objects modelled in wax which were found in an ancient Egyptian tomb, and are in an excellent state of preservation. A head of Osiris, especially, is modelled with the most intricate detail, and is an excellent example of the art of those far-off times. There are also two heads of sons of Osiris and a scarab, all modelled in unbleached bees'-wax. If the portraits in "Cera's" possession are of public personages it might be possible to identify one or more of them, and thus fix their maximum age.—Walter F. Reid.

NOTES ON BOOKS.

The Destruction of Daylight. By John W. Graham, M.A. London: George Allen. 2s. 6d. net.

This little work, which is described by the author as "a study in the smoke problem," is addressed not to the smoke expert, for it makes no pretence as to original research in chemistry or engineering, but to the manufacturer and the citizen in whose hands, according to Mr. Graham, the remedy lies. "The engineers have provided for every case smokeless, or nearly smokeless, devices . . . . . it is now for the public to amend and, above all, to enforce the law." As the human race has no greater benefactor than the sun, so it has no worse enemy than fog. It is, of course, impossible to estimate in anything but the roundest of figures the loss inflicted on us by smoke and fog, but many people will be surprised to learn that the Hon. Rollo Russell, after careful observation and consideration of the various kinds of damage done, set down the cost in 1888 to London alone as well over five million pounds. The damage to health it is impossible to reckon in coin of the realm. Nor is the blight limited to the towns themselves. At Kew Sir William Thiselton Dyer estimates the solid deposit at nearly two tons per acre per annum; at Richmond there is "a thick black deposit on the leaves of trees;" the moors in Derbyshire are dirty to sit down upon, and the sheep there are grimy in colour, while even the Lake District is not entirely free. Mr. Graham has had no difficulty in the first part of his book in making out his case for pure air and sunshine, and the latter part contains a useful account of the various means by which the smoke-fiend may be successfully combated.

The Bell Telephone. Boston: American Bell Telephone Co. 1908.

Before the expiry, by lapse of time, of the United States patent granted, in 1876, to Alexander Graham Bell, for his invention of the telephone, it was naturally the subject of a good deal of litigation in the American law courts. In the various cases, Mr. Bell was a very important witness, and gave a large amount of evidence. This evidence was collected into the form of a deposition made by him in the last case, commenced in 1887, but never carried to an issue. In view of the historical importance and the scientific value of the information contained in it, this deposition has been printed and published by the American Bell Telephone Company. It is a voluminous record of the early history of the telephone, given, of course, from the standpoint of the inventor, and as such cannot fail to have considerable permanent value.

GENERAL NOTES.

Viticulture in Afghanistan.—Information has reached India that the attention of the Amir has been directed to the possibility of growing vines for wine making, and that an expert is now investigating the question of opening up a wine industry on a large scale in Afghanistan. It is a fruit-producing country of some importance, as many Central Asian regions are, and the grapes in particular are known to be of excellent quality. The Indian journal, however, that makes this announcement points out that with over-production of claret in France, and with no facilities for transport in Afghanistan, it is unlikely that Afghan wine could

compete with the product of the great wine-producing countries of the West. There is no doubt that the Amir's known repugnance to railways is largely responsible for the backward state of the trade and development of his dominions. At the same time, it must be borne in mind that road-trains are an invention that bid fair to play a most important part in the opening up of semi-exploited regions, such as Persia, Baluchistan, and Afghanistan. They have been employed with great success in India, and where the cost of a railway is prohibitive, a far cheaper means of communication is for an average road to be laid down, and a few motors, carriages, and trucks to be run along it at regular intervals. Considering how successful breweries have proved in India, there seems no reason why wine should not at least secure a fair trial.

COTTON GROWING IN EGYPT.—In his annual report upon Egypt and the Soudan, just published, Sir Eldon Gorst refers to the cotton position in Egypt, and shows that the expectation of having a large increase in the cotton exports of that country are not likely to be realised. The area under cotton in 1908 exceeded that of the previous year by 37,191 feddans, the greater part of the increase being in the newly-converted basins of Middle Egypt, but the total output was only 6,250,000 kantars, as against 7,172,191 kantars last year. Recent returns show that the total production of cotton in Egypt is not increasing in the same proportion as the cotton-bearing area. This is partly explained by the fact that this area comprises a considerable quantity of land only recently put under cultivation, from which heavy crops cannot at first be expected, but there seems no doubt that a real falling off in the yield has occurred in some parts of Lower Egypt. A Commission was appointed last year to consider the causes of this diminution, and in its report various reasons are given, among them deterioration of soil caused by (1) the system of planting cotton every second year; (2) insufficient irrigation, which will be remedied by the heightening of the Assouan dam; (3) insufficient drainage which has caused a gradual rise in the level of the water in the subsoil to the detriment of the crops; (4) deterioration of the plant; (5) decrease in manuring, due to the quantity of natural manure available; and, (6) one of the principal causes of damage, insects and worms favoured by the recent practice of planting cotton every second year. In 1905-6 a special staff was appointed to assist the provincial authorities in executing the prescriptions of the law of 1905 for the destruction of the cotton worm, but last year it was thought that the local authorities would have learnt how to carry out the measures without special assistance from headquarters. The experience of the year has shown that it is useless to rely on the initiative or energy of the landowners, either great or small, even in a matter which so vitally affects their own pockets, and in future the former practice of creating a special service for the work will be revived.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoon, at 4 o'clock :—

MAY 26.—"The Manufacture of Nitrates from the Atmosphere by the Electric Arc." By HERR SAM EYDE, of Christiania, Norway. PROFESSOR SILVANUS P. THOMPSON, D.Sc., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

MAY 27.—"The Function of Schools of Art in India." By CECIL L. BURNS, Principal of the Bombay School of Art. PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., will preside.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 24...East India Association, Caxton-hall. Westminster, S.W., 4½ p.m. Sir Robert Fulton, "The Judicial Branch of the Indian Civil Service."

Surveyors, 12, Great George-street, S.W., 5 p.m. Annual Meeting.

TUESDAY, MAY 25...Royal Institution, Albemarle-street, W., 3 p.m. Professor John Garstang, "The Hittites (2): Recent Discoveries in Asia Minor and Northern Syria."

WEDNESDAY, MAY 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Herr Sam Eyde, "The Manufacture of Nitrates from the Atmosphere by the Electric Arc."

United Service Institution, Whitehall, S.W., 3 p.m. Dr. T. Miller Maguire, "National Recuperation."

Eugenics Education Society, Caxton-hall, Westminster, S.W., 8½ p.m. Sir Henry Cunynghame, "Alcoholism."

THURSDAY, MAY 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Cecil L. Burns, "The Function of Schools of Art in India."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. John G. Millais, "Newfoundland." (Lecture III.)

FRIDAY, MAY 28...Royal Institution, Albemarle-street, W., 9 p.m. Dr. J. Emerson Reynolds. "Advances in our Knowledge of Silicon as an Organic Element."

SATURDAY, MAY 29...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. H. R. Rivers, "The Secret Societies of the Banks' Islands." (Lecture II.)

ERRATUM.—Mr. John Ferguson, C.M.G., asks that the following correction may be made in the report of his speech during the discussion on Mr. S H. Fremantle's paper, "The Problem of Indian Labour Supply":—p. 522, col. 2, line 34-36—in the sentence, "Ceylon paid India now nearly four million pounds sterling a year for this [rice];" for the word "four," *read* "two."

Journal of the Royal Society of Arts.

No. 2,949. VOL. LVII.

FRIDAY, MAY 28, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

INDIAN SECTION.

On Thursday afternoon, May 27th, Mr. CECIL L. BURNS, Principal of the Bombay School of Art, read a paper on "The Function of Schools of Art in India." PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., presided.

The paper and discussion will be published in a subsequent number of the *Journal.*

CONVERSAZIONE.

The Society's Conversazione this year will take place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, June 29th, from 9 p.m. to 12.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These tickets will be issued shortly. In addition, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the Conversazione. On that day the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

The programme of the arrangements will be announced in a future number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 26, 1909; PROFESSOR SILVANUS P. THOMPSON, D.Sc., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Adams, Arthur, 17, Blenheim-road, Bedford-park, W.

Black, David, 128, Upton-lane, Forest-gate, E.

Huntington, Archer Milton, Audubon-park, West 156th-street, New York City, U.S.A.

Mitchell, Francis Henry O'Connor, B.A., Government School of Engineering, Insein, near Rangoon, Burma.

Nevin, Miss Blanche, Churchtown, Lancaster County, Pennsylvania, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Bishop, Rookwood Comport, J.P., Christchurch, New Zealand.

Chujo, S., 21, Sendagi-Hayashicho, Hongoku, Tokyo, Japan.

Clutton-Williams, J. P. C., Ph.D., F.S.S., care of Messrs. Balmer, Lawrie and Co., P.O. Box 4, Calcutta, India.

Harrison, C. W. Francis, Natal Government Offices, 26, Victoria-street, S.W.

Hay, Lieutenant John A. L., R.N., 13, Little Grosvenor-street, W.

Penn-Simkins, George, care of Messrs. Thomas Cook and Son, P.O. Box 26, Calcutta, India.

Smith, Thomas Fison, 4, McLean's-buildings, New-street Square, E.C.

The CHAIRMAN, in introducing Mr. Eyde, said it might be well for him to preface the paper by a word or two. The process for the manufacture, artificially, of nitrates, had been known for three or four years, in the commercial stage. In all great industrial advances one naturally went back to a beginning, and he supposed one would not be far wrong in saying that in every such advance there were four or five stages. There was first the initial stage of the discovery, when it seemed comparatively unimportant, an addition to the useless knowledge of the world. Such a discovery was made by Cavendish, 125 years ago, when

he found that the nitrogen of the air was oxidised by the electric spark. And then there came—often much later—the realisation that apparently useless knowledge was of some importance, and might have practical application. And that happened about 1898, when Sir William Crookes dared to point out—prophet-like—that the time might come when the world's supply of food would be imperilled by the increase of population and the increase of the wheat-consuming peoples of the world, and when, therefore, agriculture would fail to keep pace with the food needs of mankind, unless new sources of artificial manures could be discovered to replace the limited supply of natural fertilizing agents. For it was only too well known that the supply of nitrate of soda from Chili was limited, and would come to an end before very long. The third stage was that of technical realisation. The inventor came along and discovered the way of putting the piece of useless knowledge into useful shape. And here came in a gentleman whose name was well-known in science—he regretted he was not present to-day—Professor Birkeland, whose researches began with the Aurora Borealis, and turned on the question of the effect of producing electrical discharges in the presence of a magnetic field. He then observed a remarkable and singular electric flame, which at once appeared to him to lend itself to new developments. Calling to his aid Herr Eyde, an engineer of great experience, they together perfected the particular electric arc furnaces in which air could be burned electrically. The nitrogen of the atmosphere, inert in itself, combined with a portion of the oxygen, and as a result gases were produced which could be absorbed and turned into nitric acid or nitrate of lime, a material of which more would be heard from the author. Then there came the stage of commercialization. The invention having been made, it was put into operation on a sufficiently large scale. And in the exploitation of the invention our friends in Norway showed themselves amply equal to the occasion. He (Professor Thompson) had the opportunity, nearly three years ago, of visiting the first little factory at Notodden, which had since developed into a very large place—the author would say how many thousands of horse-power there were at present utilised for the production of the new nitrate of lime; and with that great commercial development the new industry had been begun. Lastly, there was the stage for the utilisation of the products of the new industry, where the question turned entirely on its agricultural value, and not only agricultural, because the new products were utilised for other industries, such as the manufacture of explosives, and of coal-tar products. So that in many ways it was a new discovery, which had made itself felt, and was still making itself felt, in different directions, which appealed to a very large section of the civilised world.

The paper read was—

THE MANUFACTURE OF NITRATES FROM THE ATMOSPHERE BY THE ELECTRIC ARC—BIRKELAND-EYDE PROCESS.

By Herr Sam Eyde,
Of Christiania, Norway.

More than a hundred years ago, Priestley and Cavendish observed that the oxidation of atmospheric nitrogen took place on heating in an electric flame, and men like Sir William Crookes and Lord Rayleigh have, with others in recent years, given valuable contributions to the subject. With respect to later experiments before those of Birkeland and Eyde, which are of a more practical nature, the work which Lovejoy and Bradley have done should be mentioned as very important. Time will not admit of entering into the details of the various systems. In shortly describing the difference between previous methods and that of Birkeland-Eyde, it must suffice to say that the latter have applied large quantities of electric energy in the electric arc, and have found out the best method of doing this, while it was previously believed that it was small quantities of energy that gave relatively the best results. It is on that assumption that the apparatus employed by them was constructed. Thus the invention of Birkeland-Eyde completely revolutionised the theory of the process of atmospheric combustion.

By bringing great quantities of energy into the electric arc, and finding the most suitable electric conditions and most serviceable types of furnace, Birkeland-Eyde created the synthetical nitrate industry.

I venture here to express my belief that, however many systems may be discovered in the future, and whatever improvements any of these systems may effect, with regard either to the product or the method of production, they will all, in a greater or lesser degree require to employ large quantities of energy in the electric arc.

In order to explain the Birkeland-Eyde method, it is necessary first to describe the flames, consisting of arcs of light, which are used in the electric furnaces.

The formation of the flame occurs through an arc of the electric flame being formed between the points of the electrodes, which are close to each other. By this an easily movable and flexible current is established which, with the arrangements made, will be found in a highly magnetised field. The electric arc that has been formed, moves on

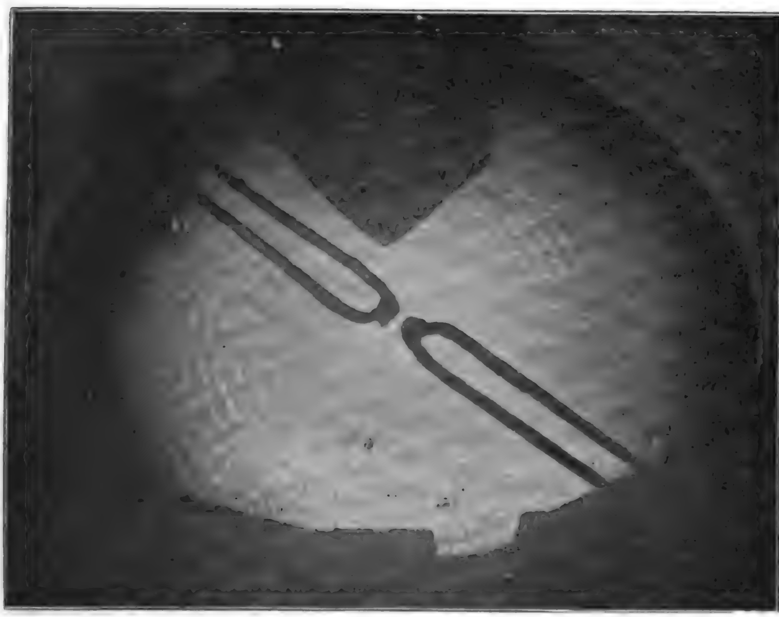
account of this magnetic field with great velocity perpendicularly to the lines of force, and the electric arc's foot draws back from the points of the electrodes. When the length of the electric arc increases, the electric resistance becomes greater and the tension increases, until it becomes so great that a new electric arc starts from the points of the electrodes.

To regulate the current, an inductive resistance is used in series with the flame. With alternating current, all these arcs are formed in opposite directions and appear to the eye to be circular discs. It appears that we have discovered in this flame a powerful technical means for the oxidation of the nitrogen of the air. The flame in our furnaces burns with a steadiness that is really astonishing.

On electrodes of 1·5 cm. thick copper tubing, through which water passes for cooling them, one can take up over 1,500 horse-power, with a flame 1·8 m. in diameter. The chamber in which the flame burns is circular, of only a few centimetres width, and about 2 metres diameter. After the oxide of nitrogen is formed in the furnace, it is converted in the oxidation tank into dioxide of nitrogen, and in the absorption towers into nitric acid.

From furnaces no larger than could be held in the hand, and which took an energy of some few horse-powers, we have attained to types which can, as mentioned, take an energy of more than 1,500 horse-power, and from absorption apparatus of glass globes of a few litres capacity, to absorption towers of granite with a capacity of 600 cubic metres each. We have in the course of this period of developing our method had four experimental stations. The first attempts were made at Frognerkilens factory in 1903. As we could not obtain more than 20 kilowatt of electric energy there, the experimental station was removed in October, 1903, to a building of our own on Ankerlökken, with power from the Christiania municipal electric power station, and, to obtain still more power, to Vasmoen, near Arendal, and later to Notodden.

Fig. 1.



Birkeland-Eyde Electric Furnace.

The Furnace House.

The building in which the furnaces are placed has a floor surface of about 2,000 square metres. It is entirely constructed of masonry and iron. In the basement are tubes for admitting the air and others for carrying off the gas. The power from our station at Svælgfos is brought in by 18 copper wires, each 12 millimetres in thickness. When these

have been brought into the furnace house, they pass through oil-cooled current converters. In order to be able to supply each furnace with the amount of power desired, each is furnished with an induction coil, by means of which the power is regulated as required. The induction coil serves, moreover, to make the flame in the furnace steady and even while working. Of the 36 furnaces installed, 32 receive their power from Svælgfos and 4 from Tinfos power station.

The flame chamber of the furnace is formed of fire-clay brick, through the walls of which the air is conveyed to the flame. The nitrous gases formed in the flame escape through a channel made along the casing of the furnace, which, like the flame chamber, is furnished with fireproof lining.

With this furnace we have achieved such steady working, that it burns for weeks without any regulation worth mentioning. It may further be stated, that the maintenance of the furnace and its repair are simple to a degree, as the most exposed portions, the electrodes, only require to be changed every third or fourth week, and the fireproof masonry every fourth to sixth month.

The temperature in our flames exceeds 3,000 or perhaps 3,500 degrees Centigrade. The temperature of the escaping gases may vary between 800 and 1,000 degrees during ordinary working. The furnaces are made of cast steel and iron, the middle of the furnace being built out to a circular flame chamber. The electrodes are led radially into this flame chamber. By aid of centrifugal fans, the air is brought into each furnace through tubes from the basement.

When the air in the flame chamber has been treated by the electric flames, the nitrous gases formed pass out through a channel built along the casing of the furnace and thence out through the lower part of the furnace to two fireproof-lined gas-collecting pipes, about 2 metres in diameter, which convey the gas through the basement out to the steam boiler house. In the boiler house, the gas passes through four steam boilers, in which the temperature, which was, as mentioned, 1,000 degrees Centigrade, is reduced. The heat given off by the gas is used for concentrating the products, and in the winter time for warming the factory buildings.

FIG. 2.

VIEW OF NOTODDEN FACTORY.

The steam produced in the boilers is utilised in the further treatment of the products. In the boiler house there are also two large and two small air compressors, which supply compressed air for pumping acids and lye in the factory's various chemical departments.

The gases pass on from the steam boilers through an iron pipe into the cooling house, with the object of completing the cooling commenced in the steam boilers. This cooling is necessary in order to obtain a suitable absorption. Each cooler consists of a great number of aluminium tubes, over which cold water runs, while the hot gases pass through them. The temperature of the gas is considerably reduced. From the cooling chambers the gases go on to the oxidation tanks.

These oxidation tanks are vertical iron cylinders, lined with acid proof stone. The object is to give the cooled gases a sufficient period of repose, in which the oxidation of the oxide of nitrogen may have time to take place. The necessary amount of oxygen is present in ample quantity in the air which accompanies the gases from the furnaces. From the oxidation tanks, the gases are led into the absorption towers. All the towers are filled with broken quartz, which is neither affected by nitrous gases, nor by nitric acid. To assist the passage of the gases on their way from the furnaces, there are centrifugal fans, constructed of aluminium, on each row of towers.

The gases enter at the base of the first tower, go up through the quartz packing and thence by a large earthenware pipe enter the top of another tower through which they pass downwards through the quartz to the bottom of the third tower, and so on, until the air, relieved of all nitrous gases, leaves the last tower. Water trickles through the granite towers and this is gradually converted into a weak nitric acid, while the liquid used in the wooden towers is a solution of soda. The absorbing liquid enters the top of the tower and is distributed in jets by a series of earthenware pipes, so that the permeating gases come in immediate contact with the absorbing liquid. In the granite towers nitric acid is thus formed, and in the wooden towers a solution of nitrate of soda.

The liquid emerges in a constant, even stream from the bottom of the towers, that from the granite towers running into a granite cistern. Hence it flows into the "montejus" which serve to pump up the acid, which has to pass repeatedly through the tower before it has become strong enough for the purpose for which it is intended. The "montejus" are of stoneware strengthened with iron shields, are worked by compressed air, and send the acid up into large stoneware jars. From these jars the acid again runs through the towers as described. The "montejus" work automatically. The wooden towers are percolated, as already mentioned, by a solution of soda, otherwise the whole process is practically similar to that in the granite towers. The solution of soda, owing to its far greater power of absorption, effects the separation of the last remains of nitrogenous gases from the accompanying air. Of the entire quantity of nitrous gases passed through the absorption system, about 97 per cent. is absorbed. The finished nitric acid coming from the towers, which has a strength of about 30 per cent. by volume, is collected in granite cisterns, from which it is drawn to what is called the "dissolution works." These consist of granite vats filled with limestone, over which the acid is poured. This drives off, with violent effervescence, the carbonic acid contained in the limestone, while the nitric acid takes its place and forms a watery solution of nitrate of lime or calcium nitrate. This solution of nitrate of lime is now pumped into vacuum evaporating apparatus. The object of boiling in vacuum is the well-known fact that great saving is thereby effected in the heat required.

The steam required for the evaporisation is obtained from the steam boilers, heated, as before mentioned, by furnace gases. The concentration of the nitrate solution in the evaporising plant is continued until the specific weight of the liquid at a given temperature shows a content of 13 per cent. of nitrogen. This solution is then sufficiently evaporated, and can be pumped up into the solidification chambers. These are fitted with shallow iron pans, under which cold air is pumped to accelerate cooling. After some time, the nitrate stiffens into a brittle, crystalline mass, hard as stone. This is broken up into lumps, and is taken into the crushing machines. These consist of ball crushing mills, which reduce the mass to a granular state. The coarse powder so produced is raised by elevator to a vat, from the bottom of which it is tapped into casks holding 100 kilos net weight.

The barrels are made at our own coopers' shop and are lined with paper to guard against damp. The colour of the product depends on the limestone used in the manufacture. The nitrate of lime is used in various chemical works as well as for manure, the only difference being that, for the former purpose, the product is not ground fine, but is run direct in the liquid state into thin iron drums, in which it stiffens into a solid mass.

The Manufacture of Nitrite.—Nitrite of Soda.

It now remains only to mention the further treatment of the nitrite formed in the alkaline towers. When this is pumped away from the towers, it contains, besides nitrite and water, also some nitrate of soda, and bi-carbonate.

The further process is designed to separate the pure nitrite from the other substances. This is accomplished by first boiling away some of the water, which is done, as in the

case of the nitrate solution, by steam from the steam boilers, heated by the furnace gases. The nitrite solution, concentrated to a suitable boiling state, is run into crystallisation pans, in which the crystallisation of the nitrite takes place. The crystals are separated by centrifugal means and are conveyed by a screw transporter to a drying apparatus, where they are subjected to a current of hot air. The finished product is then run into casks containing 300 kilos each. These are likewise made in our own shops. This nitrite of soda is used as the raw material in the manufacture of certain kinds of aniline colours. The manufacture of nitrite is carried on in a special building.

In the entire process of manufacture, both of nitrite and nitrate, no coal is used; all the machinery is worked by electric power, and for heating and evaporating the nitrate and nitrite solutions, the only steam employed is that obtained by the hot gases passing through a system of steam boilers.

We are, moreover, in our industry, not confined to the two products hitherto mentioned, nitrate of lime and nitrite of soda, we have possibilities for the development of a whole series of new industries, of which I will specially name the production of nitric acid, nitrate of ammonia, nitrate of potassium and others.

We have succeeded, in conjunction with the Nobel (nitro-glycerine, &c.) Syndicate in concentrating our weak acids, by means of gases from our furnaces, to acids of a high percentage which can be transported.

Agriculture.—Trials with Nitrate of Lime.

In recent years a number of well-known men and institutes connected with agriculture have undertaken numerous experiments for the purpose of testing the effect of the nitrate of lime under various climatic and other conditions and on various kinds of soil. These trials have been made in Norway, Sweden, France, Germany, Austria-Hungary, Italy, and also in the United Kingdom.

All the experiments have fully confirmed the expectation which was held forth by men of science when this new manure first appeared, viz., that one pound of nitrogen in the form of nitrate of lime has the same effect, both in quality and quantity, as a similar amount of nitrogen in the shape of nitrate of soda, or, in other words, that nitrate of lime is equal to nitrate of soda as a manure.

At times, variations may be observed one way or another, in one case in favour of the nitrate of soda, in another in favour of nitrate of lime. But especially in soils deficient in lime, the nitrate of lime has proved superior.

A number of agricultural chemists have conducted pot-experiments to compare nitrate of lime with nitrate of soda. I may name amongst others:—Professor Sebelin, the College of Agriculture, Aas, Norway; Dr. E. Solberg, head of the Agricultural Experiment Station, Trondhjem, Norway; Professor Söderbaum, Sweden; Professor Paul Wagner, Darmstadt, Germany; Professor Th. Schloesing, jun., Paris; and Mr. James Hendrick, chemist of the Highland Society of Scotland.

They all affirm that the nitrate of lime has proved to be fully equal to nitrate of soda as a manure, as long as the same quantities of nitrogen are employed. Professor Wagner adds, that the nitrate of lime is preferable on soils that are deficient in lime.

The field experiments are of still more practical importance, and a number of such have been made in various places in different countries. Especially extensive and exact field experiments have been made in the Scandinavian countries.

Norway.—Professor Bastian R. Larsen, conductor of experiments at the Norwegian College of Agriculture, has, from 1904 to 1908, carried out a series of the most careful experiments to compare nitrate of soda with nitrate of lime.

Several parallel trials have been made each year, some on the college grounds, some on land in various parts of the country.

Putting the results for ordinary manuring with nitrate of soda at 100, the results for similar manuring with nitrate of lime have been:—

Potato crop 1904	146·3
,, ,, 1905	100·9
,, ,, 1906	97·1
,, ,, 1907	109·3
,, ,, 1908	100·0
Green fodder on marsh land 1906	106·1
Top dressing on meadow, 1908	100·3

The professor concludes with the words:—"The experiments referred to appear, on the whole, to demonstrate that the nitrogen in nitrate of lime is equally valuable as the nitrogen in nitrate of soda."

Denmark.—In Denmark a series of experiments has likewise been carried on for the purpose of comparing nitrate of soda with nitrate of lime. The Sealand Farming Asso-

ciations have carried out 37 different trials on a number of farms. Putting the results for ordinary manuring with nitrate of soda at 100, the results with nitrate of lime are:—

	Grain.		Straw.
Experiments with—			
Rye (1907)	100·5	....	101·0
Oats (1907)..........	103·3	....	100·5
Barley (1907)	99·9	....	98·4
„ (1908)	99·7	....	104·1
			Roots.
Beetroot (1907)	—	....	97·0
„ (1908)	—	....	98·8
Sugar-beets (1907) ..	—	....	101·1
„ (1908)....	—	....	96·6

Nitrate of lime has thus in some instances been a little below nitrate of soda, in others a little above.

Sweden.—The Director, Herr P. Bolin, gives the following account of local farm trials (practical cultivation trials) made by the Hushallnings Association in Sweden.

Putting (as before) the effect with nitrate of soda at 100, the results with nitrate of lime were:—

	Grain.		Straw.
Experiments with oats in 1904 ..	104·5	..	118·0
„ „ „ 1905 ..	137·5	..	100·0
„ „ „ 1906 ..	105·0	..	93·4
„ „ hay, 1906 ..	100·9		

In these experiments nitrate of lime proved considerably superior to nitrate of soda.

The director states respecting a number of experiments with roots in 1906:—"Apart from some irregular instances the experiments made with roots appear to confirm the observations which have previously been made by ourselves and others."

The United Kingdom.—The average results of three trials of nitrate of lime with oats made by Mr. James Hendrick, chemist of the Highland and Agricultural Society of Scotland, has been:—

	Yield per acre. Grain.		Straw.		
	lbs.		cwt.	qr.	lbs.
1. No manure	2,348	..	33	0	21
2. Phosphate and potash only	2,532	..	37	1	6
3. Same as 2 with nitrate of soda	2,774	..	41	3	1
4. Same as 2 with sulphate of amm.	2,774	..	41	3	24
5. Same as 2 with nitrate of lime	3,121	..	43	1	13

In these experiments nitrate of lime proved considerably superior to nitrate of soda.

Experiments with oats at the West of Scotland Agricultural College by Professor R. Patrick Wright.

Average of Two Trials.

	Yield per acre.				Ratio.	
	Grain.	Straw.			Grain.	Straw.
	lbs.	T.	cwt.	qr.		
Experiment of 1907.						
Nitrate of soda..	1890	1	12	3	100	100
Nitrate of lime..	2040	1	10	1	108	93
Experiment of 1908.						
Nitrate of soda..	2777	2	1	3	100	100
Nitrate of lime..	3121	2	3	1	117	107

In both the instances here quoted, nitrate of lime has thus shown itself to be superior to the nitrate of soda as a manure for oats, when the same quantity of nitrogen is employed, especially when the chief object is the weight of grain.

Experiments on roots at University College, Reading, by Professor John Percival:—

	Yield.
1. Nitrate of lime, $1\frac{1}{2}$ cwt. per acre ..	37 tons.
2. Nitrate of soda „ „ ..	36 „
3. Sulphate of ammonia „ ..	32·5 „
4. No manure	27·75 „

It should here be observed that the largest crops have been obtained with the use of nitrate of lime, even when the same gross quantities have been employed, notwithstanding that the nitrate of lime only contains 13 per cent. of nitrogen against 15 per cent. in nitrate of soda and 20 per cent. in sulphate of ammonia.

Experiments Made by Professor B. W. Bull, of the Essex Education Committee.

Mangold Experiments, 1908.

	Tons.	Cwt.
1. Dung, Superphosphate and Nitrate of Lime	29	12·8
2. Dung, Superphosphate and Nitrate of Soda	28	3·6
3. Dung, Superphosphate and Sulphate of Ammonia	26	7

A Trial of Slag, as a Spring Application.

	Tons.	Cwt.
1. Dung, Superphosphate and Nitrate of Lime	22	15·7
2. Dung, Superphosphate and Nitrate of Soda	21	18·7
3. Dung, Superphosphate and Sulphate of Ammonia	19	2·1

Svælgfos Power Station.

Svælgfos power station is about four and a half kilometres, barely three English miles, from Notodden factories, on the Tinn river,

which, by the regulation of the lakes Tinnsjoen and Mosvand, has been brought up to a constant supply of seventy-five cubic metres of water per second.

The power station consists, in its main features, of a weir or dam, by which the water level has been raised seventeen metres (about fifty-six feet).

A tunnel leads the water to the basin, whence it passes through four channels through the rock and lined with iron to the four turbines.

The effective height of the fall is forty-six and a-half metres—nearly one hundred and forty English feet.

There are four turbines installed, each of from ten thousand to eleven thousand seven hundred and fifty horse-power, thus, under normal circumstances, yielding forty to forty-five thousand turbine H.P.

The turbines are fitted with two wheels, to which the generators are coupled. The number of revolutions is two hundred and fifty per minute. They are constructed by the firm of Voith in Heidenheim.

The generators were built by the Allmänna Svenska Electriska Aktiebolag, Vesteras, are three-phased current machines, with fifty periods per second, six hundred ampères per phase, and a tension of ten thousand volts, delivered directly upon the line.

The power is conveyed to Notodden by three transmitting cables, each of six wires, and a fourth cable will shortly be added in order to utilise the power more completely.

The power station is erected in the bed of the river itself close in under the almost perpendicular western bank, and all the materials had to be lifted by cranes, fifty metres up or down. The heavy portions of the machinery were carried over to the power station by the aid of a very powerful aerial ropeway, stretched from the road on the east side of the river to the edge of the precipice.

This power station is of considerable interest, not only as being the largest water-power station in Europe, but on account of the plant there installed being doubtless the largest in the world at the present moment.

DISCUSSION.

The CHAIRMAN (Professor Silvanus P. Thompson) said that the account given by Mr. Eyde, who had taken so large a part in the development of the furnace and the factory, as well as the engineering works, was of great interest. The paper presented many aspects from which discussion might arise, and to an English audience perhaps the most interesting question was that of the agricultural application of the products of the new industry. He asked His Excellency the Norwegian Minister if he wished to say anything.

Mr. JOHANNES IRGENS (the Norwegian Minister) said he was not prepared to enter into any discussion of the subject, but he would like to say that the new industry just described was considered in his country to be of the greatest national importance. It gave employment to hundreds of workmen, in a locality where formerly there were only wild scenes of Nature, and though these were very picturesque, his countrymen preferred the present situation. In conclusion, he thanked the Royal Society of Arts and the Chairman of the occasion for their very kind welcome to his distinguished countryman.

Mr. A. D. HALL (Rothamsted Experimental Station) said that he welcomed the new nitrogenous manures, and he trusted that the proprietors of the various kinds would so cut one another's throats as to reduce the price of nitrogen to the farmer. Experiments had been made at Rothamsted with nitrate of lime, and they gave practically the same results as did nitrate of soda; and it was recognised as a thoroughly valuable fertilizer. On occasion it might prove to be considerably more valuable on certain soils than nitrate of soda, because in some work recently carried out it was found that one drawback to the use of nitrate of soda—on a clay soil nitrate of soda resulted in an unkind texture of the soil—was the preferential selection on the part of the plant for the nitric acid, leaving the base to combine with the carbonic acid secreted by the plant. The part left behind had an extraordinary effect in destroying the texture of the soil. Under the same conditions nitrate of lime would leave behind a very useful carbonate of lime, so that the deflocculent effect of nitrate of soda would be avoided in the new fertiliser. Speaking from his experience with the samples of nitrate of lime which he had seen, he would say that the only difficulty which they wanted to avoid, from the farmer's point of view, was in its mechanical condition. To use such a concentrated fertiliser was rather too costly, and its deliquescence rendered it necessary that it should be handled quickly after the casks had been unpacked. But no doubt these difficulties would be remedied, and then the farmer would have at his disposal another fertiliser of an extremely valuable class.

Mr. MARTIN ROBERTS asked if the author would give some idea of the cost of production; first, as to the current consumed; and secondly, the cost of the finished product.

Dr. RUDOLPH MESSEL said that in view of the remarks of Professor Hall about the deliquescence of the nitrate of lime and the condition in which the pro-

duct was issued, he wished to ask why the basic nitrate of lime was not used instead, as he recommended some years ago. He had no commercial interest whatever in the matter, but he had suggested that the nitrate of lime should be made in the form of a powder, or cast into blocks, in which form it could be sent out, even without the necessity of using casks. The saving in the cost of package alone would be considerable.

Mr. PORTHEIM asked whether for large cargoes, or for carrying any distance, the acid salt did not get too sloppy; and whether it was not a fact that the serious difficulty, in long transit and for sea voyages, unless it was carefully packed in separate casks, was that the material as a whole would rapidly absorb moisture from the air and arrive in a deliquescent condition. That was a point which he regarded as of great importance.

Mr. J. ROBINSON said he would like to hear what was the cost of the power used, because he thought that by utilising waste heat and gases in Great Britain they would be able to produce power at cheap rates, and comparable with those in Norway.

The CHAIRMAN said he was one of the few people who had had the opportunity of seeing something of the industry in its native place. That was nearly three years ago, when the industry was only in its beginning, and the factory at Notodden had only 2,000 horse-power available against the 40,000 at present used; and they had only three furnaces going, against 32, and before the development of the particular waterfall which was so well shown by the pictures. It was also before the barrage and channel had been made—a notable piece of engineering. Not the least interesting aspect was that which concerned the electrical engineer, namely, the generating station, and the very large power units contained therein. He had seen the Boïlefos, at Arendal, and had also visited one which the author had not mentioned, but in which he was interested, the Rujkan, in Telemarken, where there was available at least 220,000 horse-power. Already preparations had been made for regulating the flow by dams still higher up in the country, and projects were maturing for utilising that enormous power in two stages—1,500 feet was too high, on account of the great pressure generated. And when that was accomplished, there would be available an enormous source of power. In reference to the question which had been asked as to whether we, in England, were likely to be able to compete with that by the utilisation of waste furnace gases, he almost wished we might, but Nature had not blessed this country with such enormous waterfall powers. But though furnace gases were at present a drug on the market, he thought that by the time the necessary plant had been erected to utilise them the financial situation would be far from an easy one. He had been struck with the careful organisation in the factory which led to such economies in labour. Even in the first small factory, the amount of labour for supervision was very small, but it was proportionately very much smaller in the present large factory. But what struck him most of all was the method in which the whole finances of the undertaking were managed. There was no hawking about of a concession, no flaming prospectus to attract the greenhorn, no great names to show what a magnificent board of directors the venture possessed. The matter was arranged in a way which he thought they should all admire. They in this country had suffered from enterprises, themselves reasonable and scientifically sound, and commercially good if properly worked, being wrecked by being made the subject of commercial speculation before they had reached the paying stage. The electrical industry of this country was to-day under a very considerable cloud, a great part of which was due to the insane manner in which capital had been raised for all sorts of schemes which ought never to have been undertaken at all, or in a more quiet and reasonable way, without being over-capitalised. Their friends in Norway satisfied substantial bankers, chiefly of that country and of Sweden, that an industry could be created, and they called in privately the best men they could get from Germany, France, and Switzerland to advise them as to the possibilities, and test what had been already obtained on a small scale with 2,500 horse-power. And then, without asking for a penny from the subscribing public, the industry grew. It was not only a scientific process but science entered into its finance. He wished we in England could have schemes handled in the same way, and that we might be delivered from the unscrupulous promoter, who had played such a sad part.

Mr. L. GASTER asked whether it was true that there were difficulties in outsiders getting concessions, on account of the restrictions imposed by the Government, and whether the foreign capitalist could be interested in the development of water power without having to go to Sweden for it.

Herr EYDE, in reply, reminded the meeting that he was not a part of the Government of Norway, but he had not previously heard that foreigners were so anxious to bring their capital to Norway. He could be sure of getting the amount of money he required. As the Chairman had rightly said, if an undertaking was good and sound, the money for it would be forthcoming. He really could not undertake to give information as to the cost of production and such information could not fairly be demanded, but he hoped their shareholders would get a profit out of it. With regard to the hygroscopic nature of the material as sent out at the commencement, they had very much trouble in that way, but now they had learned how to manage better, and he thought most people who received the material were satisfied with the form in which it came. Experience in its use was naturally required if the best results were to be

obtained. But nothing came to perfection at once; there was a gradual improvement, and it was the desire of the makers that such should be the case with this product. With regard to erecting plant in England, he hoped there might come a time when that was possible, but the output of the furnace and the cost of upkeep of the furnace were items which entered into the practicability of the matter. His own view was that even if such cheap power could be procured, they in this centre of trade and commerce would not utilise it for such things as nitrate manufacture, but on much larger schemes.

On the proposition of the CHAIRMAN, the author was heartily thanked for his paper.

THE TURKISH MOHAIR INDUSTRY.

It has been said that the goat, more than any other factor, has assisted the rural population of Asia Minor to destroy the magnificent forests which once extended from Smyrna through to Konia, the ancient capital of Karamania. Not only have the peasants and nomads destroyed the timber for the sake of firewood, but they destroyed it also in order that their goats might obtain suitable pasture. The goats in their turn prevented the new shoots ever after from replacing the trees which had been cut down. Goats, therefore, compose one of the chief sources of wealth of the country people in Turkey, and on account of the dry, saltish ingredients of the soil of the interior highlands, these are the animals which are best adapted to be reared on the least amount of money. They are also able to withstand the great extremes of heat and cold experienced in the plateaux of Asia Minor. In summer they wander with their owners over a vast extent of territory, and in winter they are sheltered in droves in rude sheds of skins and bark. The American Consul at Smyrna says that goats in Turkey usually belong to Turks, Kurds, and Yaruks, who, apart from the milk and flesh, prize the animal on account of its hair, which is becoming an increasing article of commerce from year to year. The price of a goat, unless it be a genuine Angora, is about the same as that of a sheep. At feasts and barbecues, which take place on all the religious and national holidays of Turks and Greeks, the goat takes a prominent part. The black goat species is shorn once a year, and the hair is used for making sacks for carrying olive oil and figs to the markets of Smyrna and Constantinople. The finest kind of leather is also made from the skin of the Broussa and Karchissar goat, and is sold principally to dealers in Vienna and Leipzig. Apart from the local use of goat hair and skin, large quantities are exported to foreign countries. The number of goats in Asia Minor is estimated at 3,000,000, and the value of the mohair annually produced is estimated at nearly £850,000. Small quantities only are shipped through Smyrna, Constantinople being the chief centre of the trade, which is practically monopolised by British merchants, who keep Bradford dealers and manufacturers well supplied with Turkish mohair. The Angora goat is famous the world over. Its native home is not the district of Angora alone, but it is to be found on the slopes and in the valleys of a great stretch of country which extends southwards through the heart of Anatolia. Its hair or wool is indispensable in the manufacture of manifold varieties of textiles. In Smyrna, even mohair is used in the production of certain grades of carpets. Two hundred years ago, the Angora goats of Armenia supplied the finest texture for making wigs which were commonly worn in those days by Europeans, and especially was this the custom at the various Courts. Anatolian mohair is used in making alpaca cloth for umbrellas, and it also enters largely into the make-up of certain cloaks and overcoats. Many yarns are made from the soft fibres. There are also some primitive sack-making industries in the interior of the country which cater for the tobacco trade, by supplying dealers with high-class sacks for exporting the seasoned leaves. It will thus be seen that mohair is adapted to many forms of usefulness. Once there was an important weaving industry in Angora. As far back as 1812, no less than 1,000 hand-looms furnished employment to 10,000 weavers. But for fifty years this industry has been dead. With the introduction of high-class machines, manipulated by skilful hands in the textile factories of Europe, the manufacturers of Angora at once gave way before this competition, and mohair and camel-hair is now exported by Armenian traders as a raw product. After Bradford, the factories of Roubaix, in France, consume the largest quantities of mohair. Of course, it must not be understood that European competition has completely crushed out the home weaving industry. Such is not the case. Even in Angora an extensive home industry still exists. Shawls and robes are still produced in large quantities, and are much prized on account of their durability and originality of design. All over Asia Minor, in fact, peasants and Yaruk women are to be seen sitting in their primitive houses, or goat skin tents, busily engaged in weaving some article for the nearest bazaar. Many attempts have been made to transplant the Angora goat to other countries. In 1890, it was sent to France and Spain, and about thirty years ago some high-class Angoras were smuggled out of the country at great expense and shipped to the Cape and Natal.

THE RUSSIAN OCCUPATION OF TABRIZ.

The advance of a Russian force under General Snarsky to Tabriz and the despatch of further reinforcements seems to betoken the long expected occupation, if not annexation, of the province of Azerbaijan, of which Tabriz is the chief town. The avowed objects of the Russian advance, as stated by Sir Edward Gray, "are to guard the Consulates, protect foreigners, and make sure of the opening of the

roads for food supplies," but in the highly disturbed condition of Persia it would not be surprising if these measures were spread over a lengthy period. Azerbaijan lies in the angle formed between Russian territory in the north, Turkish territory in the west, and the Caspian in the east, but it does not actually reach that sea, as a narrow strip of territory belonging to the Ghilan province runs up along the western shore of the Caspian past Astara, as far as the frontier river of Aras. The Consular report on the province for 1907-8 which has just been issued by the Foreign Office shows a considerable decline in trade as compared with the previous year, due in great measure to the troublous condition of the country. As in all other parts of Persia, the imports which amounted to more than a million sterling in 1907-8, exceeded the exports in value. Russia naturally stands first in the list of importing countries with a total of £476,488 worth of goods, the British Empire second with £343,489, and Austria-Hungary a very bad third. Our contributions are mainly cotton yarns, thread and tissues, woollen goods, tea and a little indigo, the last two items being of course from India. Nearly three-quarters of the Russian imports represent sugar. The chief exports from Persia are carpets and fruits. The best approach to Tabriz is by rail from Tiflis and Batum, but the railway goes no further than the frontier town of Julfa, the interval between that town and Tabriz being covered by a Russian road, one of the very few roads existing in Persia. It is along this road that General Snarsky and his reinforcements have made their advance.

HOME INDUSTRIES.

Unemployment Insurance.—The scheme of labour exchanges sketched last week by the President of the Board of Trade as the outline of the proposals the Government will submit to Parliament for the better regulation of labour, recalls the great work done by the London and India Docks Company, in 1891, by their policy of reform by "de-casualisation." Up to the time of the Dock strike, in 1889, the bulk of the work of the docks, on the north side of the river, was performed by purely casual labourers, taken on by the Dock Companies' foremen from a struggling crowd at the entry to each department. At least 10,000 men competed regularly for work that only required 3,000. The fact that credentials were not wanted, that anybody might compete for work at the docks, and stand an equal chance of getting it, attracted a perpetual stream of weaklings and failures from every other occupation. The work of many of these men was dear at 4d. an hour, and the system of dock employment was described as, in effect, "a gigantic system of out-door relief." But after the strike, in 1891, the Dock authorities determined upon a sounder system of selection. Men were ranked as permanent, "A," "B," "C," and casual. The permanent and "A" class were men on weekly wages, the men in the other classes were engaged and paid daily, but the "B" men had the preferential right to be employed next, after the regular staff, and before any "C" men were taken on, while the "C" men had a similar preference over the casuals. Within the "B" and "C" classes there was a similar grading of men, according to their place on the lists. The object aimed at was regular attendance for work, and a premium was put upon good behaviour since men were moved up and down the lists according to their merits. But although this reform did something, it did less than was expected, the weak point being that the company would not offer at all times a sufficient chance of work to secure the regular application of even all its "B" men. Owing to the great varieties of work a man might sometimes do better as a casual at one place than as a "B" man at his proper department. The Dock departments were too small to stand apart, and to maintain each its own reserve of labour, and so it was decided to make the whole of these northern docks into a single labour market, within which the required supplies of men should be directed from a central office to the different work places. This organisation has gradually developed until now 80 per cent. of the work done by the London and India Docks Company is performed by weekly labourers, and 20 per cent. by preference men and casuals. The preference lists are no longer important, the "C" list has disappeared, even "B" tickets are not much regarded, the permanent and "A" classes engross nearly the whole field of employment. In his "Unemployment" Mr. Beveridge states that whilst in 1891-92 the work performed by the weekly staff under the London and India Joint Committee was 45 per cent. of the whole, for the years 1902-4 it averaged 78 per cent. "The system," says Mr. Beveridge, "which obtains has the effect of shaking down to the tail end of the lowest list the men who are not industrious, steady, or honest; they only get work in emergencies, and the tendency is for them to drop off altogether."

Percentage of Unemployed.—The group of trades which the Government have selected to be the first subject of experiment in insurance against unemployment are "house-building and works of construction, engineering, machine and tool making, ship and boat building, vehicles, sawyers, and general labourers working at these trades." This group of industries comprise some 2,500,000 adult males, roughly speaking one-third of the total population of the United Kingdom engaged in purely industrial work. The unemployed percentage never fluctuates down to zero in any one trade. To take the three chief trades —named by Mr. Churchill—during the past twelve years the lowest figures recorded for the building trade were 0·8, in May, 1897; for engineering, 1·9, in January-February, 1897; for shipbuilding, 1·4, in July, 1897. To quote Mr. Beveridge once more, from 1881 to 1901, the persons returned as occupied in the census group corresponding to engineering, shipbuilding, and metal trades, increased in number

from 978,000 to 1,475,000, or more than 50 per cent., while money wages in engineering rose as from 88·36 to 100·29. The numbers in the building trades rose from 926,000 to 1,336,000, or 44 per cent, and the money wages from 85·5 to 100·0. The numbers in woodworking and furniture rose from 219,000 to 308,000, or 41 per cent., and those in the paper and printing trades from 196,000 to 334,000, or over 70 per cent. But during all this growth in the numbers employed—a growth in each group of twice or more than twice the rate for the general population—there was never in any of the groups a year without an appreciable number of skilled and organised workmen out of employment. For each group taken as a whole there appears to be much the same irreducible number below which the year's unemployed percentage never falls. In the best years all the groups alike tend to have about 2 per cent. unemployed. Even in a fluctuating trade like engineering a very large proportion of men escape unemployment altogether. In Tables compiled by the Amalgamated Society of Engineers (Manchester and Leeds districts), and giving the distribution of unemployment in the nine years 1887-95, it is shewn that the percentage unemployed for some time during the year was, taking the mean 29·7, rising as high as 39·8 in 1892, and falling to 18·0 in 1889. Irregularity in each year is concentrated on a minority, but the minority is always a fairly large one, and the Table referred to above shews the rather curious result that almost as large a proportion of workers (21·4 per cent.) became unemployed during the best years as during the worst (26·4 per cent.).

Marine Insurance. — The Marine Insurance (Gambling Policies) Bill now before the House of Commons is warmly opposed by underwriters. The object of the Bill is excellent. It is to put down the very objectionable practice which has become common during the last few years of placing lines upon ships on the chance of the vessel, or vessels, being lost, the assured, who has no *bona fide* interest, receiving the amount insured under a *p. p. i.* (policy proof of interest) policy. A considerable portion of more or less ordinary insurance has, for many years, been done *p. p. i.*, but, in the Bill, the two classes of operators, the legitimate, and the illegitimate "spotters," as they are called, are not sufficiently discriminated, and the lack of complete definitions in the wording of the Bill may, if allowed to remain, lead brokers and underwriters to avoid the ordinary and uncomplained of, as well as the extraordinary and properly denounced, *p. p. i.* transactions. As, however, the authorities have no wish to interfere with the unobjectionable operators, it may be assumed that the Bill will be so amended as to make the meaning clear; otherwise the re-insurance market may be seriously affected.

The Coal Trade and the Eight Hours Act.—The Eight Hours Act comes into operation in July, and it looks as if it will be the occasion of serious disputes in the coal trade. The object of this Act is to shorten the hours of labour, its effect must be to lessen wages if the view of employers prevails, and to increase the percentage of administrative charges if it does not. In Wales, masters and men are in sharp conflict, and in Scotland the employers have given notice of an intended reduction in wages of 12½ per cent. on the 1881 basis, which is equal to sixpence per day, and would bring the day wage down to 6s. 6d., the minimum wage under the working agreement made some years ago, when the Conciliation Board was reconstituted. Under its constitution this Board can adjudicate on claims to advance and reduce wages between 5s. 6d. minimum and 8s. maximum, but it cannot decide either above or below these rates. The minimum rate has, however, been ignored by the Scottish Miners' Federation under the working agreement, they having resolved on their own part that the minimum shall not be 5s. 6d. but 6s. per day, and they say that the present demand of the coalmasters is in effect to break the minimum wage. But the masters have never consented to the alteration of the minimum from 5s. 6d., and in these circumstances it is not easy to see how it can have been brought about. Either party can retire altogether from the contract by giving a stipulated notice, but no such notice has been given by the federation, and the miners are still represented on the Conciliation Board, which meets again next week, the idea being to temporise on the chance of an improvement in trade, of which there is no present appearance. The men seem determined not to have the minimum wage reduced below 6s., and the Miners' Federation of Great Britain has passed a resolution to do all in their power to prevent the wages of the Scotch miners falling below the present rate of 6s. per day. They have also declared by resolution that they will decline to accept any reduction in wages demands by any colliery owners as a consequence of the coming into operation of the Eight Hours Act. This Act may curtail output, but the smaller output will have to meet the same administrative charges. The employers affirm that a large majority of the collieries in Scotland are already working at a loss, and that if they are to be kept open, a reduction in wages is indispensable. The men gain the shorter hours, but they refuse to pay the price. Here are all the elements of a determined industrial conflict.

CORRESPONDENCE.

BOOKS ON WATER-MARKS.

Permit me to add to the list of "Books on Watermarks," given in the *Journal* of January 29th a small, but interesting work on the subject which is, doubtless, of sufficient importance to be included. It is:—

1856 (2nd edition). Richard Herring. "Paper and Paper-making, Ancient and Modern," with introduction by the Rev. George Croly, LL.D. London: Longmans. [Contains 30 samples of paper, several with "light and shade" water-marks, produced by a method then recently developed by William Henry Smith.]

The date of the first edition, which was issued by subscription, is not clear from the second, but it appears to be 1855. ROBERT STICHT.

Queenstown, Tasmania,
April 8th, 1909.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

GLAZIER'S LEAD VICE.—Can any member give me any information concerning the introduction of the glazier's lead vice? The earliest examples I have come across are those in the museum at Bruges, which are dated 1622, but it is certain that the practice of drawing out the leads in a machine, instead of using the rough castings direct, as was done in the earliest times, was introduced much before this. I would like to find out if any specimens of earlier machines are extant or if there is any evidence as to the time of their introduction.—N. H.

AMPHIBIOUS CARRIAGE.—Where can I find particulars of a carriage which was designed, I believe, in the early part of last century for running on land and crossing rivers?—LONG ACRE.

ANSWERS.

GOURDS AS WILD DUCK DECOYS.—"W. M." will find a description of the method in which gourds are used as wild duck decoys in the "Hand-book to the Weapons of War and the Chase" exhibited at the Horniman Museum:—"The natives of Venezuela obtain wild duck by a very ingenious method, also practised in China. The birds occur in great numbers in certain lakes and arms of the sea, but they are shy and difficult of approach. Some time before beginning the attempt the Indians hollow out large gourds, which they set floating on the water so that they finally reach the part where the birds are. These are at first afraid of the gourds and avoid them, but after a time they are regarded as harmless and natural objects. The Indian then cuts apertures for the use of his eyes in a similar gourd and places it over his head. He is then able to get among the ducks and capture as many as he wishes by seizing them by the legs and jerking them under water, when they soon drown. Each duck as it is killed is attached to the man's girdle, and an experienced hand will get all he can carry without alarming the survivors."—FOREST HILL.

CACAO BEETLE.—A useful little pamphlet on the "Insect Pests of Cacao" has just been published by the Imperial Department of Agriculture for the West Indies, in which the following methods are recommended for dealing with the cacao beetle:—"When it is known that the grub is in the tree, it may be dug out or the tunnel probed with a stout wire. The presence of this grub may be detected by the chips and excrement thrown out at the mouth of the burrow. The bark over the infested area shows a dried and shrunken appearance, and by removing a portion of such bark the burrow may be found. Any wounds made in the tree in digging out the beetle grubs should be promptly tarred over, or treated with a mixture of rosin oil and tar, to prevent the entrance of fungi. It will probably be best to remove all dried bark, and thoroughly clean the wood, wherever these injured places are found. If the wood thus cleaned is properly tarred over or painted with rosin oil mixture, the bark will grow over the wound satisfactorily. The adult beetles are active by night, and may be found resting on the trunks and larger branches of the cacao tree in the early morning. At this time they may be collected, and if thrown into the water, to which a small amount of kerosene has been added, they will be quickly killed. In Surinam, it is the common practice to tie large pieces of bark of the silk cotton tree to the trunks of the cacao, to furnish a hiding place for the beetles. They may be collected from these places during the day. It would seem likely that strips of burlap (bagging) tied round the cacao trunks would, as in the case of silk cotton bark, furnish convenient places for collecting these beetles. In Grenada, the cacao beetle is trapped by leaving the branches which are cut from the trees on the ground for about three weeks. All wounds on the trees which might attract the egg-laying beetle are tarred carefully. The adult beetles will visit the dead branches on the ground and deposit their eggs. These branches are then collected and burned. It is necessary that the branches be thoroughly destroyed. If they are neglected or left too long, they become breeding places for increasing the numbers of the beetles."—GRENADA.

GENERAL NOTES.

THE MANCHESTER CANAL.—Manchester has been a port for ocean-going steamers for fifteen years, but it will surprise many to learn that in money value of imports and exports of merchandise in 1907 Manchester ranked fourth of all the ports of the United Kingdom. London and Liverpool were, of course, easily first with totals exceeding £300,000,000 sterling each. Hull came third with £70,000,000, and Manchester next with £47,000,000, for the first time slightly exceeding Glasgow. Yet in March last the exports of cotton goods from Manchester was only 11 per cent. of the aggregate from all British ports. Manchester, where most of the goods were packed, would seem to be the natural shipping port, and cargoes, case goods especially, arrive at their destinations abroad in better condition if shipped at Old Trafford after a minimum of handling than if embarked elsewhere. Between 1895 and 1907 there was an increase from £13,000,000 to £47,000,000 in the values of merchandise in and out of the port. There was a set-back last year due to the general depresssion of trade, and the loss of an exceptional coal traffic, but ultimate financial success may be confidently expected, and directly and indirectly the canal has benefited Lancashire very considerably. It has brought money into Manchester, reduced port charges at Liverpool, and the cost of inland transit; stimulated Liverpool and Birkenhead, and found employment for many hundreds of labourers. The canal is one of the great works of the world, and is the first instance of an inland town constructing a waterway 36 miles long and 28 feet deep from the dry to the sea, and fitting its docks with the most up-to-date equipment.

CO-PARTNERY.—Encouraged by the happy introduction of a co-partnery scheme into the shipbuilding yards Sir C. Furness has made a somewhat similar proposal in connection with the Wingate Colliery. Having with two others purchased this colliery Sir Christopher Furness proposes to work it in co-partnership with those who get out the coal. The colliery produces one of the best known gas, household, and steam coals in the north of England. It yields about 350,000 tons of coal per annum, and employs rather over 1,400 men and boys. The whole property, including 1,000 acres of freehold estate, with £7,000 invested in Consols, has been bought for £175,000. A company with £200,000 capital has been formed to take over the property, and Sir Christopher Furness and his two partners will hold three-fourths of the shares, the workmen holding the other quarter. Every employee, whatever his status, will become a member of the co-partnery by signifying assent to its principles and acquiescing in the regular deduction of 5 per cent. from his pay until the shares to be allotted to him, and which he must apply for, are fully paid. The labour co-partners will participate to the extent of their share holdings in such profits as may be paid in dividends by the company. The control of the company's affairs will be vested in the board of directors, and no one but the management will have authority to discharge or engage workmen. Alongside this administration, however, there will be a colliery council composed equally of representatives of the directors and of the employees, a body which will have power to investigate and brings efforts of conciliation and persuasion to bear upon controversy between employees and employers, or their representatives. Failing agreement, matters in dispute are to be referred to arbitration by a court of representatives of employers and employees presided over by the county court judge of the district, or his nominee, the chairman of such court to be regarded in the last resort as the final arbiter in all matters of dispute. The working of this experiment in co-operation will be watched with interest.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, JUNE 1...Royal Institution, Albemarle-street, W., 3 p.m. Dr. T. G. Hopkins, "Biological Chemistry." (Lecture I.)

WEDNESDAY, JUNE 2...Royal Archæological Institution, 20, Hanover-square, W., 4½ p.m. 1. Nina F. Layard, "A Note on Some Early Crucifixes, with Examples from Roydon, Ipswich, and Marlborough." 2. Mr. Francis W. Reader, "Exhibition of an Early Bone Crucifix lately Found at Clare Market." 3. Rev. H. Bedford Pim, "A Note on Fonts at Barnard Castle and Sedgefield, County Durham."

THURSDAY, JUNE 3...Aeronautical (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 4 p.m.

Chemical, Burlington-house, W., 8½ p.m. 1. The Wolcott Gibbs Memorial Lecture, by Professor Frank Wigglesworth Clarke, of Washington. 2. Mr. A. Scott, "The Molecular Weight of Tetraethylammonium bromide and the Atomic Weight of Carbon." 3. Mr. V. H. Veley, "The Rate of Formation of Azo-derivatives from Benzenoid Diamines." 4. Mr. A. H. Salway, "The Synthesis of Substances Allied to Cotarnine." 5. Messrs. J. C. Irvine and A. Hynd, "Monomethylfructose and its Derivatives. Constitution of Fructose diacetone." Mr. W. H. Mills and Miss A. M. Bain, "Optical by active δ-oximino-hexahydrobenzoic Acidand the Configuration of the Oximino-group. Preliminary Note."

Linnean, Burlington-house, W., 8 p.m. 1. Prof. J. A. Thomson, "The Alcyonaria of the *Sealark* Expedition." 2. Mr. H. A. S. Gibson, "The Cephalochorda of the *Sealark* Expedition." 3. Mr. R. W. Harold Row, "Report on the Porifera (collected by Mr. C. Crossland) in the Red Sea."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. W. E. Dalby, "A Modern Railway Problem: Steam *versus* Electricity." (Lecture I.)

FRIDAY, JUNE 4...Royal Institution, Albemarle-street, W., 9 p.m. Professor J. R. Fleming, "Researches in Radio-Telegraphy."

Geologists' Association, University College, W.C., 8 p.m. Mr. Leonard Johnston Wills, "The Fossiliferous Lower Keuper Rocks of Worcestershire."

SATURDAY, JUNE 5...Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. F. Blackman, "The Vitality of Seeds and Plants: (1) a Vindication of the Vitality of Plants."

Journal of the Royal Society of Arts.

No. 2,951. VOL. LVII.

FRIDAY, JUNE 11, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the galleries of the Natural History Museum, South Kensington, on Tuesday evening, June 29th, from 9 p.m. to 12.

The Reception, by Sir William H. White, K.C B., F.R.S., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Engineers, in the Central Hall, commencing at 9 o'clock.

An Instrumental Concert by the "Red Band," under the direction of Mr. Thomas Batty, will be given in the Fish Gallery from 9.15 till 10.15 p.m., and from 10.30 till 11.30 p.m.

A Gramophone and Auxetophone Concert, under the direction of the Gramophone Company, will be given in the Shell Gallery at intervals from 9.15 p.m.

The following portions of the Museum will be open :—

The Central Hall, containing cases of specimens illustrating Mimicry; adaptation of colour to surrounding conditions; protective resemblance, &c.; also specimens illustrating the food of Fishes, and the life-history of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque deep-sea fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), the Lemon-sole (case 30), &c.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum.

Visitors travelling by District Railway (or other underground railways in connection therewith) will be allowed free use of the Company's Subway, which leads from the South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These tickets will be issued next week. No application for them is necessary. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by members, at the price of 5s. each, if purchased before the day of the Conversazione. On that date the price will be 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the Musical and other arrangements will be given in the Programmes which will be distributed on the evening of the Conversazione.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

Tuesday afternoon, May 18th; The RIGHT HON. LORD HINDLIP in the chair.

The paper read was—

CANADA AS A FIELD FOR BRITISH INVESTMENT AND SETTLEMENT.

By J. OBED SMITH,
Assistant Superintendent of Emigration, Department of the Interior, Canada.

With no little diffidence do I contemplate the comprehensive title of my paper. I realise at once the honour and the great responsibility of undertaking to discuss a matter of such moment before a society many of whose members are acknowledged "masters of finance," and men of unequalled experience in commercial matters, to whom perhaps some of my opinions may seem somewhat immature. I purpose offering some observations and suggestions which may interest those to whom it is given to influence in reality the movement of capital.

I claim to have had some acquaintance with persons seeking a livelihood in Canada, and as the human being unquestionably forms the bed-rock basis of expanding commerce, I hope I may be pardoned if I digress at times from the path leading up to so wide and brave a title into by-ways which will enable me to exhibit for your consideration some opinions gathered from many years' experience in assisting the settlement and development of a great over-seas dominion of the British Empire.

The vastness of Canada's area is now generally known to every school child and his elders—thanks to the improving means of communication with the Old Land—and I seldom refer to it except to impress an optimistic Yankee with the fact that the biggest thing in America is not the United States. Although I freely admit that there is some cold storage in Canada's Northland that we would exchange for a strip in California, still extent of territory has something to do with my subject.

I desire to point out

1. That capital already invested in Canada is safe and profitable, has been placed with selective care, and based on the reasonable needs of her great economic development.
2. That the prime needs of the Dominion and the provinces must continue to open up opportunities of securing investment for more capital.
3. That the immigration of large numbers of new settlers, with small or large capital, is changing economic conditions there, and making investments more necessary, and, therefore, more secure.
4. That opportunities are daily opening for profitable investment.
5. That American capital is seeking control of Canadian industrials.
6. That there is more than a possibility of shipping Canadian grain, with profit, *viâ* Pacific ports to Great Britain, and
7. That the possibilities of increasing commerce on the Pacific Ocean will attract capital, and warrant serious consideration.

BRITISH INVESTMENTS.

It is true that a large amount of British capital in the aggregate is invested in Canada. A prominent Canadian financial authority estimated this two or three years ago at about four hundred millions sterling in known securities, and exclusive of considerable sums in investments of which the particulars are not published.

I do not value very much sentiment in business. Capital, like water, finds its way out when the right occasion offers, and information is furnished on sound business lines. The sentiment of Canada's preferential tariff in favour of the Motherland is, to my mind, lost in the advantage of increasing trade caused thereby. Wealth primarily lies in the land. Canada is digging as much wealth from that first source as she can. She is growing more wheat per acre than the United States is growing, she is filling up her vacant spaces, and the expanding figures of the crop returns prove the wisdom of concentrating on the development of the country's natural resources; but there comes a time in a nation's history, as in every commercial enterprise, when the working capital must be increased, or development be retarded. More capital, therefore, seems to me Canada's need to-day, and it appeals at once as a sound reason for seeking British investment. It is gratifying to note that while steamship lines trading with the States are passing dividends and using reserve funds on account of last year's business losses, the Canadian lines have not suffered from the same financial stress.

Mr. Byron E. Walker, the General Manager of the Canadian Bank of Commerce, recently said:—

"The marketing of the actual proceeds of the field, forest, and mine of itself requires that large additions should be made to railroad equipment, and that other building operations should be carried out. Canada in 1908 was doing more business than was justified by the money at our command at home, or that could be secured abroad by the sale of securities the country was creating."

And Mr. William Mackenzie, President of the Canadian Northern Railway, speaking lately in Washington, said:—

"We have got to develop this country, and we cannot do it fast enough. We are short of men and short of money compared with what we can find use for. Canada is even bigger than the Americans who come into it. If it were not they would not come. They get more than they bring."

Canada's story begins with the discovery of Nova Scotia and Newfoundland by a Norwegian, Leif Ericson, nearly 500 years before Columbus found the America appropriated as the special title of the United States. After being practically forgotten for centuries, the granting of a trading charter to the gentlemen traders in Hudson's Bay in 1670 made the first real connection of at least the great central parts of Canada with British capital. It was at the same time a master-stroke of political-commercial policy which largely determined the destiny of half a continent, and disclosed the value of that vast area to the Empire. How well the venture has paid the shareholders the present market quotations will sufficiently indicate. One of the chief posts in that enormous territory, which extended originally a considerable distance south of the international boundary, was Fort Garry, or what is now the marvellous city of Winnipeg, with 125,000 inhabitants.

The Hudson's Bay Company sent their sailing vessels at specified times during the year to Nelson or Churchill on Hudson's Bay (as near Liverpool as Montreal), the cargo was transferred to large, strong row boats, and, barring an occasional portage, was transported over a continuous waterway to what is now Winnipeg.

The engineer's first report of survey presented this session to the Canadian House of Commons refers to the possibility of improving the waterway for this purpose. The project may remain in the clouds for a generation, but it is not impossible or improbable that steamers will take cargo at the wharves in Winnipeg, and deliver the products of the prairies in unbroken bulk at the port of Liverpool.

With the isothermal lines running in a north-westerly direction and the altitude of the land steadily declining as one proceeds northwards, the climatic conditions and resources of the great second-storey (as it were) of Western Canada are to-day as popularly misunderstood as were the conditions of that portion opened up by the Canadian Pacific Railway, which formed in the early eighties the subject of most outrageous criticisms.

Those who think such a project too fanciful would not be alone in their honest opinions, for so great a critic as *Truth*, on September 1st, 1881, wrote the following about the Canadian Pacific Railway:—

"It will run, if it ever be finished, through a country frost-bound for seven or eight months of the year, and will connect with the Eastern part of the Dominion a province which embraces about as forbidding a country as any on the face of the earth. The New Yorkers are keen enough gamblers and reckless enough at times, and yet it is impossible to believe that they are such fools as to put their money into this mad project. I would as soon credit them with a willingness to subscribe hard cash in support of a scheme for the utilisation of icebergs, and Canadians must know it is never likely to yield a single red cent. of interest on the money sunk in it."

What is the value of that prophecy to-day with this railway's shares over 170, and a traffic which requires 45,418 freight cars, 1,819 passenger cars, and 1,412 locomotives for its business, and having at Winnipeg the largest railway yard in the world? I venture to predict that the resources of Northern Canada will furnish results as triumphant as in the case of the Canadian Pacific Railway. *Truth* also referred on that occasion to Winnipeg as follows:—

"The people who have gone there cannot stand the coldness of the winters, men and cattle are frozen to death in numbers that would rather astonish the intending settler if he knew, and those who are not killed outright are often maimed for life by frost bites. Its street nuisances kill the people with malaria or drive them mad with plagues of insects, and to keep themselves alive during the long winter they have to imitate the habits of the Esquimaux."

That was 27 years ago; yet, notwithstanding the prophecy, Winnipeg exists in fact, and to such purpose that the bank clearings for 1908 exceeded 614,000,000 dollars. There are 377 miles of sidewalks, 300 miles of paved and graded streets, and the new buildings erected

in Winnipeg during the past six years exceed 50,000,000 dollars in value.

Further prediction was made at that time by *Truth*. "This Dominion is, in short, a fraud all through, and is destined to bust up like any other fraud." This prophecy may now be regarded as of little consequence, and the *amende honorable* was made long ago, but I quote it for the reason that one cannot place too strict a limit on possibilities that may now seem far distant. Rather would I turn to the statement made by the late Hon. Alexander Mackenzie, one of the early Premiers of Canada, during the Confederation debates at Quebec in 1865, when he said:—

"If there is anything that I have always felt anxious about in this country it is to have the British Possessions put in such a position that we could safely repose without fear of danger from any quarter, under the banner which we believe covers the greatest amount of personal freedom and personal happiness that is to be found in the world. And when we look to the vast territory we have in the North-West, we know that the great rivers which flow through that territory flow through immense beds of coal, and that the whole country is rich in mineral deposits of all kinds—petroleum, copper, gold and iron, that the land is teeming with resources of wealth, calculated to build up an expansive and valuable commerce and support a powerful nation; that all this we can touch and seize upon the moment we are prepared to open up a way to reach them, and allow the settler to enter that vast Western country, where there is hardly a white man living to-day."

Canada occupies middle ground between the East and the West, and one cannot imagine the total of her development, as only the merest edge has been trimmed by the scissors of wise commercial men, and only the top surface of a very small proportion has been scratched by the plough.

The Canadian Northern Railway is opening up a little Empire each year, and the best evidence of the magnitude and necessity for the Grand Trunk Pacific Railway is ably set out in the following interview with Mr. Charles M. Hays, the president of that trans-continental highway:—

"Bear in mind, please, that railroads are not now built as the earlier trans-continental roads were built, up hill and down dale, on an unballasted roadbed of mud. What we require to-day, and what the travelling public means to have is a first-class roadbed with such low gradients and wide curvatures that our trains can be run at very high speed with perfect safety.

"We carry our road from Winnipeg over the Rockies to Prince Rupert with a maximum gradient of 21 feet to the mile going west, and 26 to the mile going east. The immense economy in hauling freights with gradients so remarkable, every railway man must recognise. We shall be able to put two thousand tons of freight into Prince Rupert from Winnipeg behind a single engine.

"Of the seven great railroad systems which to-day cross the Rockies and reach the Pacific, the Union Pacific with grades of 116 feet eastbound, and 105 feet westbound comes nearest to us. I will tabulate for you the grades of our six competitors, and the dynamics of an engine on each.

Railroad.	Max. Grade.	Tractive Resistance in Pounds per Ton.	Gross Capacity of Engine in Tons.
Grand Trunk Pacific	26	14	2,041
Great Northern	116	50	572
Northern Pacific	116	50	572
Union Pacific	116	50	572
Santa Fe	185	76	376
Canadian Pacific	237	96	298

"In other words, the same engine could haul up the maximum grade of the Grand Trunk Pacific nearly four times more freight in a train than either the Great Northern, or Union Pacific, over five times more than on the Santa Fe, and about seven times more than can be hauled up grade on the Canadian Pacific. These are remarkable figures, I am aware, and I accept the responsibility of putting them on record.

"We expect that our easy gradients, which are due not only or chiefly to our 'generous expenditures,' but to our possession of the Yellow Hea[d] Pass through the Rockies, will in a few years twi[st] around a great portion of the wheat export trade [of] the North-West, and with the opening of the Panam[a] Canal in 1914 send wheat to Europe (let alone Asi[a]) by way of the Pacific.

"At present the wheat crop is either hurried to th[e] ports on the great lakes, Duluth, Fort William, a[nd] Chicago, during the few weeks between threshin[g] and the closing of lake navigation in November, or is held up for six months in elevators at a conside[r]able cost, or again, if it is carried through to t[he] Eastern seaboard in winter, when the St. Lawren[ce] route is closed by ice, the long haul through hea[vy] snows makes the operation difficult, costly, and e[ven] disastrous both for the railway and to the farm[er]. West-bound from Saskatchewan and Alberta [to] Prince Rupert, the grades are easy; there is v[ery] little snow in winter, so that when the Panama Ca[nal] opens in six years I look to see Prince Rupert one [of] the very great grain ports of the world. I have m[ore] than once ventured the prediction that in my lifeti[me] we shall haul to the Pacific as much grain as we s[hall] haul to the Atlantic.

"The volume of traffic coming out of the [...] North-West, if we may judge from the way sett[lers] are already swarming in, will throw far more busi[ness] upon our existing lines than they can possibly han[dle]

The present cultivated area is but six million acres. As yet we have but scratched the surface. We shall require very shortly to do what the Canadian-Pacific is already doing in Manitoba, that is, double track our road to enable us to handle the traffic. Thus, the diversion of a large portion of the far western wheat trade will advantage every section of our road; it will enable us to give settlers much lower rates, because we shall even up our loads, sending full cars both east and west instead of only east. While we send cattle, grain and minerals west to Prince Rupert, we shall haul back east the coal and the lumber which the settlers on that three hundred million-acre farm need."

General Public Expenditure.

Dominion and Provincial Government bonds have been freely accepted in Great Britain, and public funds are needed to-day for the following purposes:—

(*a*). *Construction of Canals.*—The first canal was opened in 1781. Since then Canada has expended nearly one hundred million dollars, and will spend more in her attempt to load wheat into ocean-going vessels at points near her great central prairies, and carry the wheat unbroken through the Soo Canal, which carries three times the tonnage of the Suez Canal, and other waterways to the ports of England.

(*b*). *Construction of Railways.*—The first train on a Canadian railway ran in 1836, and to-day the Dominion railway mileage is greater than that of the British Isles.

(*c*). *Postal Service.*—The first post was a mail stage between Montreal and Quebec in 1721. Now the number of Post Offices in Canada is nearly 12,000.

(*d*). *Militia and Defence.*—The first military organisation consisted of 63 men in 1653. The present ambition of the Canadian Minister of Militia and Defence is to have a Canadian army of 100,000.

(*e*) *Public and Parliament Buildings.*—The first Parliament (that of Lower Canada) was opened in 1792. Now the system of government consists of a Federal Parliament, under the (Imperial) British North America Act, with specified jurisdiction in certain matters, and a local Legislature for each province, exercising control in other affairs.

(*f*). Encouragement of agriculture and immigration; protection of fisheries and general requirements.

Besides the general public enterprises I have mentioned the development of a new country needs fostering in many ways. The Federal and provincial Governments spend enormous sums of money annually along lines of betterment, for example, river protection works, to control and prevent disaster from floods, &c.; drainage of wet lands, making them fit for the plough; bridges and roads, to give settlers access to markets; public and normal schools for the training of children and their teachers; asylums for the insane, the deaf and dumb, the blind and the incurable; assistance to hospitals; steamship wharves and docks; breakwaters; lighthouses for the coast lines, and 600 miles of inland waterways; guaranty of titles to lands; surveys and the settlement on land; destruction of noxious animals, and noxious weeds, the farmers' foes; afforestation and protection of timber (Canada delivered six million trees to her farmers last year, free of charge); fish hatcheries for re-stocking depleted waters; preservation of game; telephones and telegraphs for farm and city; dairy schools and agricultural colleges; experimental farms, and encouragement of the stock and poultry industries; police protection in wide and sparsely settled areas; bounties on manufactures, &c. Various provinces specially needing more railways pledge their credit for large sums. For example, during the session of the Alberta Legislature just closed, that province undertook to guarantee the bonds of the Canadian Northern Railway, and the Grand Trunk Pacific Railway for branch lines equalling 1,681 miles, at a cost of 27,000,000 dollars, practically leaving no corner of the province unprovided for.

These are some of the characteristics of the gigantic and complex machinery which requires much money to make the wheels go round. Does it not seem that with a goodly land, progressive people, wise and safe Governments, the natural result is a continuation of expansion, which makes investment profitable and secure?

The Minister of Finance, referring to the development of the Domnion during the year ending 30th June, 1907, showed that in the previous decade Canada's imports increased from 120,000,000 dollars to 360,000,000 dollars; her exports from 140,000,000 dollars to 260,000,000 dollars, making a total trade increase in ten years from 260,000,000 dollars to 620,000,000 dollars. He said that during the same period trade with Great Britain had increased from 100,000,000 dollars to 205,000,000 dollars; shipping arriving in and departing from Canada, from 23,000,000 tons to 37,000,000 tons; and railway mileage from 16,550 miles to 22,452 miles, carrying a

traffic which rose from 25,300,000 tons to 63,866,000 tons. During the same period the deposits in the savings banks increased from 63,963,000 dollars to 90,264,299 dollars, and the deposits in the chartered banks from 201,000,000 dollars to 589,000,000 dollars, while business failures had decreased from 13,000,000 dollars to 11,600,000 dollars.

Immigration and Settlement.

Under this head it is interesting to note that by the last census returns immigrant families settled on land in Canada in 1906 had an average of four horses, twelve cattle, five swine, and possessed an average acreage of 208 acres of farm, with 49 acres in crop. One-third of those succeeding had not farmed before going to Canada.

I suppose no one will question the statement that the essentials of the Dominion continue to be more methods of transportation and more people. Over one hundred new town sites on railway lines were put on the market last year. These places appear as a speck on the bald prairie, and with almost magical rapidity, some of them at least, become centres of distribution and prosperous villages, filling the needs of the settlers in the surrounding districts. Railway construction is proceeding rapidly, but even one thousand miles a year does not keep pace with settlement. In the prairie provinces free homesteads of 160 acres are given by the Government to every male over 18 years of age, British or Canadian born, or an alien, who, after three years' probation, swears allegiance to the British Crown. During 1908 the homesteads and pre-emptions taken up, if packed close together in a space twenty miles wide, allowing only for intervening railway sections, like squares on a chess-board, would make a strip of one thousand miles. I have suggested twenty miles in width, so that no farmer would be more than ten miles from a railway running in the centre.

Much hope is centred on a proposition to build a railway from the prairies to Hudson's Bay, so that while the Hudson Straits are open for four months or more each year, cargo vessels might carry the prairie grain direct to England without breaking bulk. This line, when built, will not, in the opinion of those qualified to judge, be more than an additional outlet for the future production of grain in the central prairie provinces, but sufficient traffic will also be available for existing railways, and the all-water routes, *viâ* St. Lawrence, and Atlantic Ports, Vancouver, and Prince Rupert. About 6,000,000 acres were under wheat in the prairie provinces last year, but the area of land suitable for wheat production south of the Saskatchewan watershed is not less than 171,000,000 acres, according to Professor Saunders, whose estimate is the lowest. One fourth of that area under wheat would supply the British Isles three times over, and Canada's home market as well.

The surface of the prairie provinces is strikingly similar to the tundras of Russia, especially along the westernmost section of the Siberian Railway. The prairies on the banks of the Yenesei equal the fertility of the renowned Red River Valley through Manitoba, North Dakota, and Minnesota, but they are at present too remote from the market to be a possible competitor. The capacity of the prairie provinces to grow wheat has been referred to by Professor Tanner, the eminent British agricultural chemist, in the following words :—

"Although we have hitherto considered the black earth of Central Russia the richest soil in the world, that land has now to yield its distinguished position to the rich, deep black soil of Western Canada. Here it is that the most fertile soil in the world is to be found, consisting of a rich vegetable humus, one to four feet deep."

And on the same question the Editor of *Commercial West* and the *North-West Miller*, in 1905, made a very modest estimate. He said :—

"When the American West was being developed the wheat acreage increased one million acres a year. For a number of reasons the increase will probably not be so rapid in the Canadian West, but it should be about 300,000 acres a year for the next ten years. That would give an acreage of about 7,000,000 acres by the year 1915, and a crop in an average year of 175,000,000 bushels."

In Western Canada over 7,000,000 acres will be under wheat in 1909.

There appear from time to time new districts claiming consideration, and there is a distinct northern trend in wheat cultivation. Last year one farmer at Fort Vermilion, hundreds of miles north of the Saskatchewan water-shed, grew thousands of bushels of magnificent wheat, which is now being ground into flour by the Hudson's Bay Company at that point. Wheat weighing 62½ pounds to the bushel has been successfully grown at Fort Simpson, 818 miles north of Winnipeg, and the continuation of the Grand Trunk Pacific Railway into the Yukon territory will bring into direct

communication a district which even now is raising a large quantity of vegetables, &c., for local use. I am aware that in the further north the possibility of frost becomes more certain, but when one recalls how the State of Kansas sixty years ago suffered annually from summer frosts, and that cultivation has driven the frost line backward, a similar effect would not seem strange in Canada, where still vaster areas are being opened up, and where, indeed, the frost line has been set back hundreds of miles already. What shall be the end when it is remembered that north of the Saskatchewan water-shed I have mentioned, and including Ungava, Keewatin and Mackenzie, the extent of this practically unknown land is over a thousand miles across, and north of Winnipeg Lake itself there is an area only partially explored, of from five to ten thousand square miles, adapted to agriculture? I recommend the perusal of the recent report to the Senate of Canada on "Canada's Fertile Northland," issued by the Minister of the Interior.

The trend of settlement in Canada, as was the case in the States, has been westward, following, and in many cases preceding, the construction of railways. As the land in the present railway belt (the more southern part of Western Canada) is being rapidly filled up, attention is being directed to the great northern reserves for other purposes than merely grain growing. The Director of the Geological Survey of Canada reports:—"Ungava possesses a belt of iron-bearing rock, probably one hundred miles long, and two or three hundred miles wide, and, in the future, Labrador will furnish a large supply of iron."

If the United States did not largely use maize for food, her present supply of wheat would not exceed the total needs of her inhabitants. That is a strong statement, but true, and shows a future near market of such capacity that may absorb all the surplus wheat Canada can produce for some years. The President of the Great Northern Railway states, that the price of wheat will never be substantially lower, and that in a very few years' time the United States will be importing, instead of exporting. The President of the Canadian Pacific Railway Company says:—

"As regards the shrinking of the American exportable surplus of wheat, there are three main factors to be considered—(1) The debilitation of the wheat areas in the Western States; (2) the increase of population; and (3) the fact that maize (the pivotal American crop) is here and there taking territory and capital from wheat."

The Special Agent of the United States Department of Trade and Commerce reported, after a lengthy investigation in Canada, that in his opinion the year 1910 would see 150,000,000 bushels of wheat grown in Western Canada. With over 7,000,000 acres under wheat in 1909 he may reasonably be correct.

These statements seem to surprise American citizens, for we find the Rev. Joseph Cook, the well-known American clergyman, lecturing recently before the Boston Club, speaking as follows:—

"Let us not underrate the British States of North America. It has been my fortune, in Manitoba and in British Columbia, to meet with experiences which have given me a new conception of the dignity of the Canadian Dominion. Conversing with a professor of a university in the beautiful and energetic City of Winnipeg, while a map of North America was opened before us, I put my compasses down, one foot on St. Paul, and left the other swinging about the chart. 'Now,' said I to my informant, 'how far north must I carry this loose foot of the compass to reach the furthest border of your good wheat lands?' 'You must carry it north,' said he, 'to the Peace River in Athabasca. On the banks of that stream the buffalo and their young may be seen feeding on grass on the 10th of May.' I opened the compasses until they reached the Peace River, some 1,500 miles north-west of St. Paul. I then swung the compasses around, and their northernmost point, when carried east, stood in the Atlantic Ocean, and when carried to the south it stood in the gulf. Incredible as the assertion may appear, there is more arable land north-west of St. Paul than east of it."

Apparently Canada's reputation has also taken firm hold in Italy, as appears by the following translated extract from a well-known journal there:—

"Fortunately the cultivation of wheat has for the past few years been developed to an extraordinary degree in the fertile and boundless plains of Western Canada, and the production is all the while increasing. The day is not very far distant when Canada, cultivated with eager industry by the robust arms of the immigrants crowding in, will become the granary of the world, as Egypt was of the Roman Empire."

Manifestly men and money are a combination that mean production and transportation of agricultural and manufacturing products, and consequent prosperity. A much larger number live on the land in Canada than in Great Britain, and her ambition is to continue along similar lines in the future, consequently emigration to Canada is a vital and desirable necessity. Those engaged in emigration work sometimes meet with a chilly reception from those who feel that people should be retained

here. Statistics show that a million babies are annually born in England, and the capacity of the British Isles to absorb that additional number each year by her commercial enterprises is not apparent. Therefore, some people have to move. During the past seven years 920,220 persons left British shores for America, while 519,845 left for Canada in the same period. I submit that it is doing good work for the Empire when Canada offers an avenue for livelihood to those who cannot find it here, and tries to divert, if possible, those intending to go to the United States. Canada is not in the "little Empire" class. If Britishers will not go to Canada, then it is hoped that they will go to some other part of the British Empire, but not out of it. Canada, however, can care for all genuine workers, with the assistance of British capital, and the diversity of occupations in the Dominion means that the immigration policy must be sufficiently elastic to meet the constantly changing conditions. The present Minister of the Interior very aptly said:—"The policy of immigration cannot be measured with the tape line, nor fitted to the multiplication table, any more than water can be measured by the yard, or peaches by the acre"

What has immigration meant to Canada up to the present? Population in 1891 less than five millions, now seven millions; the production of apples, grapes, and other fruits more than doubled, grain and field crops nearly trebled in the same period; 216,000 farmers settled on free homesteads requiring agricultural machinery, live stock, and railway development; in ten years the number of new arrivals increased from 25,000 to a quarter of a million per annum. Tens of thousands of American farmers have come to Canada, bringing with them cash and effects worth many millions of dollars. These figures sound tremendous, but in the Appendix 1 I give a sample report of such arrivals at one of the customs ports of entry on the International boundary, and Appendix 2 shows that the American settlers arriving there in 1908 made Canada richer by 65,000,000 dollars.

Canada has not balanced her account with America yet, for there are over a million Canadians, or descendants of Canadians, in the various States of the Union, driven there years ago by adverse conditions, which happily do not now exist.

Canada's population is 73 per cent. rural and 27 per cent. urban; her volume of trade has more than doubled in ten years; her relative percentage of commercial growth for seven years was 107 per cent. against 47 per cent. for the United States and 26 per cent. for Great Britain; land values have quadrupled in the west, yet they are now only one-fourth the price of similar lands in the States, hence the American exodus; 87 per cent. of Canadian farmers own their own lands; nearly two thousand million dollars represents the value of lands and buildings in connection with Canadian agriculture; she sells England more cheese than all other countries combined; her forest products equal one hundred million dollars in value in some years. The Western cattle trade thirty years ago did not exist; now there are at least a million animals at pasture on the western prairies, and twenty thousand different ranching brands are officially registered. Canada has nearly thirty thousand public schools; a greater railway mileage per head than any other country; 767 miles of electric railway; 1,000 lighthouses and lightships; 35 to 40 Chartered Banks, with over 1,500 branches; grain elevator capacity nearly 65,000,000 bushels, including those at Fort William and Port Arthur; and the population of Western Canada has increased in a generation from a few thousands to nearly a million.

Canada is blessed with a preponderating number of the middle working class; she has no aristocracy save that of worth, and very few of the poor so common in the cities of the Old World. If the view of publicists that Russia's downfall may be traced to the absence of the great middle class as a backbone is correct, then Canada is indeed favoured by Nature and by immigration. The duty of the Government is to see that no poor material is admitted to depreciate the high general average of worth in a nation of workers.

At the commencement of the nineteenth century the population of the United States did not exceed that of Canada at the dawn of the twentieth century. It was no small task for the people of the States to settle the immense areas of their Republic. Canada, with her larger area of unproductive territory, has a greater problem to solve, and figure for figure, class for class, is making a much better job of it. To the furthering of this most worthy object the application of British capital can well and safely be applied. "The nineteenth century belonged to the United States, the twentieth century is Canada's." So says Sir Wilfrid Laurier.

Perhaps it is safe to say that Canada's record is unique in her capacity to absorb capital and people, and enlarge her trade tremendously, without wrenching existing conditions at home and abroad. Her banks limited the ambitious investments of reckless customers at a time of financial stress, and although they have been severely criticised, many a man standing on the crest of the wave of prosperity must be grateful for the steadying influence of the man who holds the purse.

With advancing development prosperity is again shining on Canada, and there will come the inevitable increase in immigration. Departmental machinery will help towards satisfactory results, but the country itself, blessed with such abundant natural resources must, after all, be the mainstay of the movement.

The time when the United States abrogated the Reciprocity Treaty with Canada was the time when Canada needed outside assistance, or, at any rate, thought she did. That time is past. Canada has, by the aid of British capital and her own faith, carved her way through obstacles at one time seemingly insurmountable, and now the United States, and other foreign nations, do not leave her out of their reckonings.

Opportunities for British Capital.

Wherein do I see opportunities for safe investment of British capital in Canada? First let me say that, all things being equal, British capital will and should go in preference to some part of the same Empire, for in that kind of union is unquestioned strength. Dependence for food supplies can best be placed with component parts of the same Empire; Canada can be made to supply all Britain's needs, and perhaps in the future (not too distant) she may so far dominate the supply of the very necessities of life to foreign nations, that her say will be a mighty support when danger threatens the Motherland. The force of arms is unfortunately too often illustrated, but many battles are won and lost for Empire and home in the commercial markets of the world by men who make commerce in such a way that the fighting arm of the enemy is paralysed. The pen may be mightier than the sword, but, in my opinion, commerce beats them both.

All federal, provincial, municipal and railway bonds have behind them actual, tangible assets, and will doubtless continue to be favourably considered.

The purchase of unimproved lands for settlement purposes on the great central prairies has given the American many million dollars of profit. British capital still seems very loth to invest in what is one of the best investments to be found anywhere. The American farmer who sells his farm in the States can purchase practically four times the same area in Canada. I also favour loan company securities based on a safe cash value, whether listed on the market here or not. Private investment in mortgages on real estate is safe and remunerative.

Other fields for investment can be found in oyster growing, for home and export; whaling and fish industries; development of water power—(it is estimated that 25,000,000 horse-can be produced); prospecting and mining of coal; silver stocks on a good margin of known development; cattle and horse raising, hog raising, and meat packing; fruit raising in Nova Scotia, New Brunswick, Prince Edward Island, Ontario and British Columbia; lumber mills, pulp and paper making, iron and steel industries, flax growing, linseed oil mills, and binder twine factories; fodder and grain crops for export; poultry, sugar beets, sheep raising, tobacco (one county in Ontario produces six million pounds); iron mining and manufacturing, nickel (Canada has 57 per cent. of the world's supply); gypsum for plaster mills, mica, natural gas (Ontario alone has 392 wells); life, fire, and accident insurance companies; mills to manufacture paper from unlimited quantities of straw; oatmeal and flour mills; soap factories, fisheries, glass factories; agricultural implements and carriages; stoves and hardware; boot and shoe factories, furniture factories; cycles and motor cars, metallic roofing; cotton goods, pickle factories; blasting furnaces and smelters, and the construction of residences, large and small, in the growing towns of the Dominion. For all of the above Canada has the raw material, and an increasing demand.

Industries already generally established that can be further developed by capital, with profit, seem to be gold, silver, lead and other mining, coal mining, iron and other mineral products (the Algoma Iron and Steel plant and the Dominion Steel Company had the biggest March business in their history); factories for canning meat, fish, fruit and vegetables; water powers to supply electric energy for lighting, heating and power; the production of horses, cattle, sheep, bacon, cheese, tobacco, flax, asbestos,

Portland cement, natural gas, lumber and wood products, beetroot, sugar, and the growing and milling of food stuffs.

The rate of interest earned in Canada is, of course, higher than in the British Isles. There are splendid opportunities of investing in loan and trust company stocks. Farmers actually prefer to borrow at 7 and 8 per cent. because their agricultural operations frequently net them 20 per cent. on such borrowed capital. With more farmers each year this field of investment increases, yet I know the directors of a small loan company in Western Canada lending its money on first mortgage to artisans and others owning their own homes at a margin of 50 per cent. cash value, repayable in monthly combinations of principal and interest, who tried (and failed) to borrow 100,000 dollars on ten year debentures at 6 per cent., payable half-yearly in London —apparently because the stock was not listed in London.

American Investments in Canada.

It is stated that not less than 196,357,411 dollars of British capital went to Canada during 1908, and was there invested, as follows:— Dominion and Provincial Government Bonds, 77,598,500 dollars; Municipal Bonds, 47,433,911 dollars; and Corporation or Railway Bonds, 71,325,000 dollars. Of this enormous sum, 84¼ per cent. came from Great Britain, 12½ per cent. was subscribed in Canada (not so bad seeing she has had to sow her farthings and reap her pennies before spending them), and the United States, 3¼ per cent. I must point out that so small a percentage does not represent the amount invested last year by the United States in Canadian industrials, for it is well known that while the British investor has dealt largely in official bonds, the States have been freely placing their money in Canada's greatest industrial assets and natural resources.

Not only this, but the States are pushing trade in Canada along lines which might fairly be considered exclusively Canadian. For example, there was exported into the province of British Columbia alone during 1908, from the United States, butter, cheese, and milk valued at 180,000 dollars; eggs, 67,000 dollars; meat, 741,000 dollars; fruits, 268,000 dollars; vegetables, 134,000 dollars; hops and malt, 88,000 dollars, a total for foreign food, for consumption there, aggregating 1,865,000 dollars in one year.

Canada imports from the States large quantities of automobiles, cycles, clocks and watches, boots and shoes, and iron and steel manufactures, goods which ought to be made in Canada, or supplied by Great Britain.

I consider the estimate of 200,000,000 dollars invested by Americans in water powers and industrials in Canada is not excessive. The following is an extract from the recent report of a special representative of the United States Trade and Commerce Department:—

"The building of the Canadian industries has been due to United States capital. In the case of many industries, substantially all the capital is from the States. In other cases capital is Canadian, while the industries are managed by parties from the United States, and the articles are duplicates of those manufactured in the mills of this country (United States). No trustworthy calculation can be made of the amount of capital actually transferred from the United States to the Canadian industrial enterprises during a given period. An estimate by a Montreal bank manager of the American investments of that city fixed the maximum at 25,000,000 dollars during the past five years, although 75,000,000 dollars had been claimed. It is not, however, the actual amount of the capital that is so important, as the fact that the United States has a direct or indirect interest in so many Canadian concerns, and money is constantly flowing back and forth, some of it in the form of dividends from branch factories, and probably a larger proportion in the form of purchases of raw material and factory supplies. The establishment of branches of American factories on Canadian soil is not recent, but the movement has been very marked during the past five years. Many of these enterprises draw not only their raw material, but machinery parts and partly fabricated materials, from the factories in this country (United States). This is particularly shown in branches of the iron and steel industry."

This statement makes Canadians regret all the more the tendency of the British market to keep so strictly to official bonds, and in this connection I think it important to repeat the opinion of the London manager of the Bank of Montreal:—

"In respect to investment in water-power and industrial securities proper, England—much more Scotland—shows a marked timidity. Generally speaking the Englishman shuns water-power securities, looking upon them as highly speculative industrials, though, as a matter of fact, they are on a higher plane than industrials, in a general sense of the term, being public utility companies, more frequently than not affording most excellent security with good interest return; unlike manufacturing concerns, subject to trade fluctuations and tariff changes, they have a business in perpetuity."

This attitude gives the American his chance, and an opportunity of improving it. It would

be interesting to know why British capital continues to be so largely interested in American railways and similar ventures, when it is now admitted that the limitation of wheat-growing in the United States is already in sight, and, in consequence, railway enterprises will to some extent be checked, while railway construction in Canada is not yet one-fifth of what will be required to develop Canada's resources to an extent equal to those in the States. In this connection it will be well to remember that during the year 1908 the United States lost more people by emigration than they received by immigration.

I am regretfully obliged to admit that the Americans have been securing large interests in industrial concerns in Canada, which would afford British capital exactly the same amount of profit if invested therein. It may be said that this has been done in some cases to avoid the customs tariff, but the fact remains that there are 122 industrial concerns in Canada which are American in origin, and financed with American money, to the extent of probably 125,000,000 dollars. This list I give as Appendix 3; and, in addition, one sees frequent references to Americans negotiating for control of development schemes concerning natural resources. For example, if President Hill, of the Great Northern Railway Company, has not already secured a controlling interest in the Crow's Nest Pass Coal Company, in which district it is estimated there is sufficient coal, if mined at the rate of 4,000,000 tons a year, to last for 500 years, it is not for the want of his trying to do so; and I think it may be accepted as a fact which is much to be regretted.

Again, a party of Nebraskans, headed by President Drake, of the Standard Bridge Company, and Manager Jameson, of the Mountain Lumber Company, Oregon, are seeking timber propositions in British Columbia, and apparently have secured some, while an old-established lumber company in British Columbia, with three new saw mills in full operation, showing 17 per cent. profit, could not find a purchaser at par, or anything else, in Great Britain, during the last six months.

Gold in any considerable quantity in British Columbia, was first discovered in 1848 in Queen Charlotte Island, off the coast of British Columbia. For years attempts have been made to interest British capital in the gold deposits there, and in the enormous area of excellent coal in those islands, without success. Within the last few months this coal has passed into the hands of Americans, who need it for the purposes of the United States, and are thus able to supply the American war vessels and their mercantile marine with a commodity that cannot be found on the Pacific slopes of the American Union. Of 1,800,067 tons of coal produced in British Columbia in 1907, 673,114 tons of coal, besides 60,110 tons of coke were exported to foreign countries, and British Columbia sells with profit in San Francisco, notwithstanding the heavy import duty there.

An American syndicate has acquired a central location in the city of Toronto, and is about to erect thereon a palatial hotel, costing a million and a half dollars.

The whaling industry in Canadian waters between Herschell Island and Cape Bathurst, and at other points, is monopolised by Americans and their capital. A New York syndicate, headed by Mr. W. R. Hurst, have recently acquired an area of pulp wood in Newfoundland, and intend erecting a ten million dollar plant, capable of producing 450 tons of paper per day. The halibut fishing industry on the Pacific coast is carried on principally by an American company, whose last year's catch was worth two million dollars.

Even ancient relics are not free from the desire of our American cousins. During last month they secured from Canadian owners the boiler and other parts of the steamer *Beaver*, the first steamboat to ply in regular trade along the Pacific coast. Although the boiler was not the original boiler that came round the Horn, this did not prevent them from setting these relics up with great pride as a permanent attraction in the city of Seattle.

A.B.C. Route for Grain.

I desire to call special attention to what is sure to become an important alternative trade route. I refer to the A.B.C. route for Canadian grain, so called from the combination of the initial letters of Alberta and British Columbia. Since the great increase in grain growing in the province of Alberta, the comparative cost of transporting the grain over the long railway journey, eastward from Calgary to Lake Superior, a distance of 1,260 miles, against 644 miles westward from Calgary to Vancouver, has become a live question, if Alberta wheat is to have the same chance in the world's markets as that grown in Saskatchewan and Manitoba. The western route, *viâ* Vancouver

and Cape Horn or Suez Canal, is open all the year, while most of the grain hauled in winter time from the prairies eastward is stored at Lake Superior points until the spring. Comparing the winter rates, it is found that the rate on grain from points on the Calgary and Edmonton Railway to Lake Superior is 25 cents. per hundred pounds, and by rail from Lake Superior to West St. John, Boston, or New York, 25 cents more. The water-rate on the Atlantic varies from 5 to 7 cents, which makes a through Eastern rate to Liverpool and London not less than 55 cents per hundred pounds. West-bound the rate is 22½ cents from all Canadian Railway Pacific stations in Alberta to Vancouver, and the Chargeurs Reunis line, operating freight steamers to Liverpool *viâ* Cape Horn, have quoted a grain rate of 22½ cents, making the total west-bound through rate to Liverpool and London 45 cents (a saving of 10 cents per hundred pounds), but at present there are no elevators at Vancouver to permit the loading of grain in bulk into steamers, so the saving of 10 cents per hundred is largely used up in the cost of sacking the grain. It is understood that a similar rate to Europe can be made *viâ* the Suez Canal. Vancouver is under no special disadvantage, as all grain forwarded from San Francisco, Portland, Tacoma, and Seattle is shipped in sacks. There is no elevator at any of these ports for handling grain in bulk, and Vancouver is likely to have, through the enterprise of the Canadian Pacific Railway, the first shipping terminal elevator on the North Pacific coastline. If 10 cents per hundred pounds advantage can thus be obtained for Canadian wheat in freight rates, thereby saving the cost of storing and insuring the grain for the winter, it will be worth while indeed. It is quite within the range of possibility, with up-to-date methods of handling, and increased competition for the trade from Prince Rupert and Vancouver, that the point where the advantage will disappear, or nearly so, between East and West shipments will be set eastward as far as Moose Jaw, and thus affect the profits of wheat-raising on all the central prairies.

The distance from Vancouver to London by the Suez Canal is 15,200 miles; *viâ* Cape Horn and the Straits of Magellan 14,200 miles, and when the Panama Canal is opened the distance will be reduced to one-half. A continuous stream of grain westward to the Pacific Coast could not fail to stimulate return cargoes, and the quicker returns consequent upon an all-the-year market must be beneficial to the Canadian farmer, and a strong incentive to immigration and commercial enterprise; yet the shippers of grain westward must exercise care as to the quality, as only special grades can at present be sold at Pacific points.

Not only does there appear to be immense need of capital to develop the A.B.C. grain route, but trade with the Far East and Mexico from Canada is increasing, and capable of still further development. I attach as Appendix 4, a statement showing the trade of Canada with China and Japan during the past ten years, from which it will be seen that while the imports from China and Japan in 1908 scarcely exceeded those of the ten previous years, the exports to those countries from Canada have more than trebled.

Although the native Mexicans are not consumers of wheaten bread, and subsist on rice, corn and beans, there has been latterly an increasing demand for Canadian wheat, sufficient to induce the Mexican Government to take off practically the whole of the duty on foreign wheat going to Mexico. This has created some trade, but while it is not considered by those in a position to judge, that Mexico will, to any very considerable extent, afford a permanent market for Canadian wheat, one cannot foretell the ultimate result of the great international development that will take place when the Panama Canal is opened for traffic. The past two years have been exceptionally dry, and the native crops in Mexico have been largely a failure. In 1905-6 Mexico bought four and a-half million bushels of wheat from Texas, but this year Texas was short, and Canada made her first shipment. Dry seasons will occur again, and Mexico will want wheat, and more and more the Pacific Coast States will cease to be exporters, requiring all their crop for their own use. Then Canada's opportunity will arise to secure what trade there is.

I have not touched upon the export of flour from Alberta mills to the Orient, but evidently those interested believe in the prospects of profitable trade, because 43 more elevators and additional flour mills are to be built in Alberta this year.

For years Canada has been shipping lumber from Vancouver to Japan, China and Manila, and within the last month has even made a shipment to Calcutta.

During 1908 the ship tonnage cleared at the Port of Vancouver exceeded three millions, which is in excess of the Puget Sound ports.

and compares most favourably with San Francisco, and in point of total tonnage with Montreal, though not in value of trade.

Extracts from an article on Canadian trade with Australia, in *The Westminster*, Toronto, of February, 1908, and written by a former official of the Canadian Manufacturers' Association, appear in Appendix 5.

Development of Pacific Trade.

To a large extent what has been said refers to present conditions and those of the immediate future, but I desire earnestly to call the attention of those interested to the tremendous possibilities of trade development on the Pacific Ocean when and so soon as the Panama Canal shall be open for traffic. Even now negotiations are pending for the carrying of freight from Vancouver in Canada to England by utilising the Tehuantepec Railway, and were the gradients of that short railway not so difficult it would be a very serious competitor with other lines of transportation.

Professor Chisholm, in the third edition of of his "Commercial Geography," says:—"If British commerce has in recent years advanced with less strides than that of some other countries, geographical ignorance on the part of merchants and business men can be set down as one of the principal causes." I do not consider that Canadian business men are any more free from the suggestion of geographical ignorance, but I would suggest a serious study of the new conditions that are even now arising upon the Pacific Ocean.

The development of coast-wise and overseas shipping and commerce between countries bordering on the Atlantic Ocean was an achievement of the nineteenth and preceding centuries; the opportunity of the Pacific has arrived with the twentieth century. The opening of the Panama Canal, fraught as it will be with vast importance to the commercial interests of America, cannot be ignored by British capital, and future results may be nearer realisation than we think. The leading Pacific Coast newspapers joyfully assert, that "Taft's administration will see vast developments, particularly in the regions facing the Orient."

Geographical conditions oblige us to look to the maritime importance of British Columbia for the best evidences and future possibilities for Canada in the Pacific trade. The ports of Vancouver, Victoria, and Prince Rupert are destined to play an important part in the development of the Canadian Dominion. A few facts will suffice to show that there is the substantial backbone of natural resources to the ever-increasing trade now passing through British Columbia, which it is sincerely hoped will be manifolded when the vast possibilities of profitable enterprise become known to the man with the purse.

British Columbia has 182,000,000 acres of timber lands, only 16,000,000 of which have been alienated, the balance being wisely put under reserve by the Provincial Government. The 160 saw mills in the province manufactured, in 1907, 846,000,000 feet of lumber, of which 67,000,000 feet went to the United Kingdom, South America, South Africa, China, Japan, Germany, Fiji, Mexico, Australia, Chili, Peru, and India, and these points very generally indicate the trade connection the States have from their ports on the Pacific.

On Vancouver Island the Naniamo coal measures cover 200 square miles, and those of Comox 300 square miles, the latter having, it is estimated, workable coal to the extent of 6,000,000 per square mile. Canada has practically the only readily available supply of good coal on the whole Pacific coast, and yet already some of this has been alienated to Americans.

The imports and exports of British Columbia amounted to 28,000,000 dollars in 1904, and increased to 48,000,000 dollars in 1908. Wheat has been shipped every year from Portland, Tacoma and Seattle to the United Kingdom, and other parts of Europe, but coming events will render it incumbent on Canada not only to supply an increasing amount of foodstuffs to Europe and the Ear East, but, in effect to monopolise the whole grain trade on the Pacific coast, because of the inability of the United States to increase her wheat crop beyond the needs of her own people. Obviously, Canada can concentrate a large percentage of the commerce of the North Pacific at least, for her own ports.

Regular steamship communications exist from British Columbia ports to China and Japan, Honolulu, Australia, Alaska, and for 4,350 miles to Dawson City in the Yukon. There is also a coastal service to Puget Sound ports, San Francisco and Mexico. With the opening of the Panama Canal the whole feature of the Pacific trade will be changed. The United States is not spending 300,000,000 dollars on that waterway for nothing. The saving from San Francisco to New York by water will be 5,100 miles, and the saving from

New Orleans to the Golden Gate, nearly 8,000 miles over the present all-water route.

Already, as I have stated, an attempt is being made to ship to and from British Columbia by way of the Tehuantepec Railway from the Gulf of Mexico to the Pacific Ocean. It is true that that line has heavy gradients, but it is only 192 miles long. Consideration will show some of its comparative advantages over present routes. For instance, from Liverpool to Montreal, thence to Vancouver, would be 2,772 miles by water and 2,906 miles by rail. From the Gulf end of the Tehuantepec Railway to Liverpool is 3,596 miles, and from the other end of this short line Vancouver is 4,020 miles by water, or by this route 7,616 by water and 192 miles by rail.

Somewhere on the Alberta and Saskatchewan plains is a changing point, east of which it will be more profitable to ship wheat to Atlantic ports, and west of it *viâ* Pacific ports, and this line will be set nearer Winnipeg when the Panama Canal is opened. It is quite certain that a new route would mean the moving of wheat every month of the year, and keep the supply to this Motherland steadily flowing.

Mr. Mann, Vice-President of the Canadian Northern Railway, stated a few months ago, that the productions of the whole of Alberta and of Saskatchewan, as far east as Battleford, would probably find their natural course to Europe *viâ* the Panama Canal; and Mr. Charles M. Hays, General Manager of the Grand Trunk Pacific Railway, is of the same opinion. Mr. J. J. Hill, of the Great Northern Railway, said, "The effect and possibilities of the Panama Canal route cannot be surmised."

When at the Pacific coast last month, Mr. William Whyte, second Vice-President of the Canadian Pacific Railway, said, he believed that Alberta export wheat is all destined to go through Vancouver, probably in sacks, by the Tehuantepec route rather than round the Horn. All these transportation experts appear to be alive to the situation, and the man with the capital must not be surprised at extensive calls for money.

There is trade in fish and other commodities, ready for development, between Canada and the Catholic countries of North and South America on the Pacific, and, when the Panama Canal is open, with Atlantic ports in North as well as South America.

The total value of goods sold by the United States to Canada last year exceeded the total value they sold to the whole of South America and Mexico combined. They want all the trade of the west coast of South America, and will try to get it.

If anything more is needed to point the importance of the situation, I would quote the following from the speeches of Mr. Theodore P. Shonts, Chairman of the Isthmian Canal Commission. In speaking of his holdings in the Tennessee Coal and Iron Company, Mr. Shonts said:—

"When the Panama Canal is completed, every (100 dollar) share of my stock in that company will be worth 1,000 dollars. The opening of that canal will make Birmingham, Georgia, the Pittsburg of the South, and will give it the same relationship to the Gulf of Mexico that Pittsburg now has to the Atlantic coast.

"The Panama Canal will be open for traffic in 1915, and I estimate the volume of traffic passing through it the first year will amount to 7,000,000 tons.

"If conditions were to remain permanently as they are to-day, there might be a doubt as to the wisdom of this expenditure; but when we look around and see the rapidly increasing population and resulting density of traffic in our own country, when we observe that our vast transportation facilities, which made possible our country's wonderful expansion and form the underlying basis of our prosperity, are simply swamped with the traffic which they are called upon to handle, and when we contemplate the enormous amount of money that must be raised to provide adequate facilities for taking care of the increased volume of business, we are compelled to conclude that the superfluous population of the earth will soon be forced into other channels than the United States, and is not unlikely to move into the vast fertile plains and rich regions of our South American neighbours.

"Hence it is our duty, if we expect to get our share, to set forth immediately and systematically to develop means to acquaint ourselves with their needs, so that when the canal is opened and ships can go from our home ports to the ports of the west coast of South America without breaking bulk, we may be able to take advantage to its maximum possibility of this physical transformation of the earth.

"If our prosperity is to continue, we must have wider markets for our goods—what better fields for exploitation exist than the territory of our next-door neighbours in Central and South America? But while it is necessary to have the markets in which to sell our goods, it is equally necessary to have the facilities with which to transport them. I mean by this that the volume of our export trade to-day is seriously hampered by the overtaxed condition of our railways, especially at terminal points; in fact, it is a serious question whether it has not reached its limit under present conditions."

And from the positive side of the case the following extract from an official publication

of the British Columbia Government, published some years ago, has a special interest now:—

"Communication and the exchange of products with Australia and the Orient will continually improve, the exports and imports of the province itself, and of Eastern Canada through her ports, must increase very considerably until something like a balance of population and trade on Atlantic and Pacific shores has been arrived at. It would be difficult to estimate the extent which the commerce of British Columbia will have reached by that time. Situate as it is, the only British possession on the eastern shores of the Pacific Ocean, and sharing with its next-door neighbours on Puget Sound in the only first-rate harbours north of San Francisco, a very great proportion of the whole volume of possible trade must be transacted through her ports. At the same time, she possesses every requirement for the construction of vessels whether of wood or iron, and since so large a number of her inhabitants are drawn from the nautical classes, it will not be surprising if she holds her own, both in the building and manning of ships, against all competitors on this side of the the world.

"It must not be forgotten that the Dominion holds the quickest route to China and Australia by several hundred miles, which in these days, when so much store is set upon quick transit of goods, is no small advantage; and it would indeed be an extraordinary reversal of all past traditions if British merchants failed to make use of their opportunities or to compete with something like success against their energetic neighbours in the States."

Conclusion.

Everyone who has the welfare of Canada at heart would deprecate any suggestion or attempt to offer for investment of capital anything but a safe and sound enterprise, and I heartily endorse the following statement by Mr. E. R. Wood, Vice-President of the Dominion Securities Corporation, Ltd.:—

"It may not be amiss at the present time to reflect that while one cannot but feel enthusiastic at the possibilities of this combination ot British capital and Canadian opportunity, yet the situation carries grave responsibilities. We must meet the British investor not merely with the good faith to which his confidence and enterprise entitle him, but with such abundant good faith as shall keep our financial reputation second to none. There must be no 'sharp' practice. A securities market, like any other market, can be spoiled by dishonesty. The magnitude of our needs shows that to spoil it would be a national calamity, and would put back the hands on the dial of progress for a generation. Every bond and every form of security offered the British investor, must bear the stamp of honesty. Canadian securities must win a name in the British market, as Canadian cheese, Canadian apples, Canadian bacon, and Canadian wheat have established their standing. In this crucial stage of our development, I venture to say that the reputation of our securities is of greater moment than the reputation of our material products, important as they must always be. It rests with all issuers of securities, with every bond dealer, broker and financier, with every financial corporation, with every municipal council, and in a more important sense with every Provincial Legislature and with the Dominion Parliament, to see that the man who ventures his money in a Canadian enterprise, is treated fairly and honestly. If there should be an occasional failure, let it be an honest failure, and in every success let the investor enjoy the full benefits of his enterprise. Canada must fully sustain the confidence of British investors."

And with this I close my paper.

Appendix I.

Arrivals from United States *viâ* Gretna, one of the Boundary Customs Ports.

An average value of 300 dols. in effects to each person—all provided with cash and live stock.

Gretna, Manitoba, April 8, 1909.—As giving an idea of the class of people coming into Canada this season from the States, a list has been compiled by the Customs officials here. The total to April 1 was 64 cars of settlers' effects, 198 persons, 264 horses and 102 cattle, with a total value of 60,000 dols., an average of 300 dols. to each person, man, woman and child. The list indicates the name of the new settlers, where they hailed from and their destination; also the number in the family, the cattle, horses and sheep, and the cash they are bringing in, as follows:—

Name of Immigrant.	Number in family.	Horses.	Cattle.	Sheep.	Cash.
					Dols.
James Muson, Laydon, N.D.; Paynton, Sask.	4	2	..	..	800
F. C. Draper, Grand Forks, N.D.; Stettler, Alta.	2	5	..	..	1,500
W. W. Osnes, Ihlen, Minn.; Camrose, Alta.	9	3	..	..	1,100
L. Kohlman, Appleton, Minn.; North Battleford	1	4	6	..	1,150
I. B. Gummro, Ovan, Minn.; Colendzo, Alta.	4	3	..	..	750

APPENDIX I.—(*continued*).

		549	673,550
	1908.		
Massachusetts	Jan., Feb., Mar.	192	117,900
	Apr., May, June	399	221,125
	July, Aug., Sept.	219	85,325
	Oct., Nov., Dec.	56	54,300
		866	478,650
	Total for four States	5,296	6,102,170

An average per capita of 1,152 dollars.

Number of immigrants from U.S.A., for calendar year, 1908, 57,124 at 1,152 dollars = 65,806,848 dollars.

N.B.—It is estimated that 70,000 will cross the border into Canada in 1909 and bring in cash and effects, 70,000,000 dollars.

Appendix V.

Canadian Trade with Australia
(By T. A. Russell).

Extracts from *The Westminster* (Toronto) February, 1909:—

"Australia is a great buying country; immense warehouses have been erected in all the leading cities, and tremendous stocks of goods are carried at every point. Practically, everything in the nature of manufactured goods has to be imported; consequently it is a market which, in many lines of goods, should be largely canvassed by the Canadian manufacturer, but he must recognise that competition is keen.

"The means of communication at present between Australia and New Zealand and Canada are not very adequate. The Canadian Pacific Steamship Company, operating with the Union Steamship Company, of New Zealand, run a line of mail steamers from Vancouver to Brisbane and Sydney, giving a four-weekly service each way. This proves very efficient for a short, direct route and for mail service, but for heavy freight which has to be sold in close competition in Australian markets, the long over-land haul makes the rate almost prohibitive.

"What is needed very much at the present time for the development of Canadian trade is a line of freight steamers plying from some Eastern Canadian port like Quebec and St. John to Australia direct. If some arrangement could be made to secure sufficient return cargo to make the line at all profitable, it would prove of great assistance to the up-building of Canadian trade in Australasia.

"In addition to this line, the Alley Steamship Company operate a line between Canada and New Zealand. These steamers leave Vancouver every two months and prove of some assistance in maintaining service between Canada and New Zealand itself. The service, so far, has not been frequent enough or dependable enough to prove of the value it should to Canadian manufacturers and exporters.

"My conclusions then are that Australasia with er large natural resources and her comparatively nall manufacturing, presents undoubtedly a large iarket for manufactured goods and that Canadian rms should find an increasing market there, in many ifferent lines. . . . .

"This means that competition from that country keen. In addition to this, large exporting counies, like United States and Germany, have their ares introduced, and, in many cases, quote very lose prices."

Appendix VI.

ome Opportunities for Investment in the Province of Nova Scotia.

There is but one tannery in the province, and iat at Pictou. Halifax would be a very natural ocation for a large tannery. The hides could be rought from South America by water carriage, as ell as from other parts of Canada.

A cannery for the canning of blue-berries and ther fruits.

A factory making a good fertilizer would receive eneral support. There are two or three such factoies in the province, but a largely increased demand.

A mill for the manufacture of paper from pulp vood.

A factory making white wear. There is no such ianufacturing concern east of Montreal.

The Silliker Car Works have continually a large uantity of refuse wood going to waste, which could e utilised with profit in the manufacture of rolling ins, clothes pins, step ladders, &c.

Factory for making cordage and twine for fishing ets.

Improved methods of curing herrings and other fish.

There is no shirt, cuff, and collar industry in any of he maritime provinces. You cannot buy a white hirt that is made east of Montreal.

A furniture factory would have abundant supply of irch and other woods. A furniture factory in Windsor, Ontario, is shipping goods to South America and Australia.

There are large beds of salt at Cheverie and elsewhere, which could be worked with profit, as Nova Scotia is the largest consumer of salt per capita, xcept Norway.

Industries subsidiary to that of the manufacture of teel and iron.

Appendix VII.

The Newer Towns and Villages of the Prairie Provinces have to-day openings for the following trade enterprises:—

7 Bakers.
17 Banks.
8 Biscuit and candy factory
8 Blacksmiths.
4 Butchers.
7 Grist mills
9 Hardware stores.
8 Harness shops.
14 Hotels
3 Implement warehouses.
3 Jewellers.
8 Creamery and cheese factories.
2 Dentists.
13 Doctors and druggists.
3 Dry goods stores.
11 Elevators.
19 Flour mills.
6 Furniture stores.
9 General stores.
3 Livery stables.
3 Lumber yards.
1 Machine shop.
4 Newspapers.
1 Oatmeal mill.
1 Planing mill.
1 Pork packing plant.
1 Soap factory.

Persons interested can be directed to a reliable person in each place.

DISCUSSION.

The Chairman (Lord Hindlip) thought it was an opportune time for the subject of investments in Canada to be put before the British public. The subject presented itself to him rather in the light of a prospectus, and he generally endeavoured to see both sides. In looking at Canada as a field for investment the first thing was to see what was bad in it. "Where is the nigger?" With regard to Canada the "nigger" appeared to be a very small one. He had been struck by the fact that the news agencies through which news filtered from Britain to Canada and from Canada to Britain were too much in the hands of the Americans, most of the news coming through New York, and if the gentleman at the end of the telegraph in New York was of opinion that the news was not sufficiently interesting he probably did not send it on either way. Then also the trades unions in Canada were very much under the control of the trades unions in Western America. Their bark, he thought, was worse than their bite. The Socialistic party in Canada appeared to be a negligible quantity. There was also a disposition, chiefly among the Socialistic element, when the danger of invasion was mentioned, to turn round and say that it did not matter much to them and appeal to the Monro doctrine. That, so far as he could say, was the size of the "nigger" in Canada. The other side of the question were the attractions of Canada, and those to his mind were very large and numerous. In the first place Canada was part of this great Empire, and as far as he could see Canada was absolutely free from any fetters of Downing-street. There was no paralysing influence of any Colonial Office clerk, and no interference of a Minister with a party programme. The Dominion Government and the Provincial Governments were bent on developing the country as fast as possible, and assisting by every reasonable means in their power anyone who wished to invest money or to farm or to start industries, or do anything to assist the country; such people were received with open arms. The province of Alberta seemed to present remarkable possibilities for investment and making money in a very short time. In the Lethbridge country for example the quantity of wheat grown to the acre was very great. During the last three years the average crop had equalled the crop grown in this

country, 32 or 33 bushels to the dry acre, as against something like 12, the average of the United States. In the last returns from the Government farm at Ottawa he believed the average was something like 50 bushels. It was quite true, as Mr. Smith had said, that America would very soon be importing wheat. In two or three years time he did not think America would export any wheat at all, and when it was considered that within probably less than fifty years America would have a population of something like 200 millions, it was a problem where the food was to come from to feed these people. Alberta wheat would have its market to the West, but would also have a market in the United States, and he thought that was where the majority of Alberta wheat would go to in the future. With regard to the various ways of transporting wheat and other products from the Pacific coast to Europe, he had been told the other day that the Tehuantepec Railway had offered a freight of 5s. less from Vancouver to London than the Blue Funnel line had offered *viâ* the Suez Canal. If that was the case it would make an enormous difference to the time taken for goods to get from London to Vancouver. With regard to the opinions quoted by Mr. Smith as appearing in *Truth* many years ago, it seemed to him that some of those opinions were also the opinions of a few people now, although not to the same extent. He had in mind a usually very progressive paper whose City editor was very often inclined unnecessarily to "crab" Canadian securities, because he seemed to think they were analogous to what he called "poker chips" in America. If any one believed that Canada was borrowing too fast, or was asking for more money than she could put up collateral security for, that person had better go to Canada and see for himself. Anybody who had been in Canada even five years ago could have no conception of what was going on in Canada to-day, or of the progress that was being made every year and every month. It was not fair to criticise unless one had tested the country recently, because the situation changed very quickly. The agricultural colleges, the Macdonald especially, and the Ottawa Government, were doing all they possibly could to improve agriculture and to teach the young how to carry on their farms at a profit. Every day experiments were being made with different kinds of wheat suitable for the northern country, the endeavour being to produce a wheat that would ripen and mature a day or two earlier than another variety, a thing that meant bringing thousands and thousands more acres of the northern territory into the limit of the cereal growing territory. The bank clearings in Canada had increased enormously this year, and during the panic in America of 1907 there was no corresponding panic in Canada at all; securities fell but they fell because people had to sell something to carry on. He was quite certain that persons who invested their money in sound Canadian investments could sleep at night in perfect security, more so than they could sleep with their money in some countries, and they would find no enterprising gentleman on the look out for profitable hen roosts.

The Hon. J. H. TURNER (Agent-General for British Columbia) said he was more familiar with the Western Provinces than with other portions of the Dominion, and, therefore, wished to confine his remarks to one or two points in connection with British Columbia. It was believed that the future trade of the Pacific would be quite as great or greater than the trade of the Atlantic, and there were some very striking things in connection with that trade that had occurred during his lifetime. When he went to British Columbia forty years ago there was hardly a steamer on the Pacific, and it took a week to ten days to travel from San Francisco to Victoria. At the present time there were very fine lines of steamers to Australia, China, and other ports, running out of Vancouver and Victoria, and the coasting trade between Victoria and Vancouver and the northern parts of British Columbia and Alaska was also carried on by fine lines of steamers. Another factor was the altered taste of the Chinaman. A very few years ago the Chinese ate nothing but rice, but they had now learnt to eat bread made from wheat flour, and thousands of Chinamen had returned home carrying the taste with them, and to-day wheat and flour were being shipped to China from Canada. There were 400,000,000 people in China, many of whom would in the very near future, he thought, be using wheaten bread instead of rice, and that of itself would make a very important trade across the Pacific. There was also the trade down the west coast of America with Mexico and the other Republics rapidly increasing, and he believed the statement made by the Chairman was quite correct that an offer had been made to carry freight from Great Britain to British Columbia by the Tehuantepec line for 5s. a ton less than the Blue Funnel line. That was a thing which would very greatly affect the trade of Vancouver, and possibly railway rates. He knew of shipments actually having been made by that line, if not at 5s. less, certainly at the same rate as the Blue Funnel line rate. The position of British Columbia made it an important section of the Dominion for the trade of the Pacific. The trade of British Columbia at present was comparatively small, but the population was also small; during the last ten years it had probably doubled. In 1901 Vancouver had 30,000 people; to-day its population numbered 90,000. Other towns were growing as rapidly. Fifteen years ago it was believed that fruit-growing was impossible, but last year British Columbia exported some 4,000 tons of fruit grown on fruit farms that were not in existence seven years ago. On the line of the Grand Trunk Pacific forty years ago the country was considered useless, but to-day friends told him that that country had an excellent climate. It was fairly dry, the cold was not intense, and agricultural

products promised to be very good. Last year, for instance, tomatos ripened in the open air very well, a thing they could hardly do in England. There were thousands of acres of land being opened up for agricultural purposes that were never dreamt of twenty years ago. That was in British Columbia alone; and when it was remembered that the whole of the Dominion possessed such resources and possibilities, there could be no better country for investing ing British capital than Canada. There were many advantages there: the best of laws purely administered and taxation light. As the Chairman had said, anyone with securities in Canada could sleep in comfort, and, he might add, get up in the morning probably to find a slight advance in price.

Mr. CHARLES GROSVENOR ROSS (of Ottawa) said that wheat was the staple industry of Canada, and would continue to be so, because it offered an occupation for a large number of men of limited means. In Alberta, the northern limit of the wheat-growing territory lay much farther north than in Eastern and Central Canada, running into what was at present entirely unoccupied territory. The most magnificent wheat could be grown there. In the year of the World's Fair at Chicago he was living on the stage route between Calgary and Edmonton, and during that time the Rev. Mr. Brick, a missionary from Fort Dunvegin, came down with a small load of wheat on his way to the World's Fair, and that wheat took the first prize against the wheat of the world. That showed what the northern country could do. Canada to-day, he understood, was the only country in the West where "No. 1 hard," the highest grade of wheat, could be grown, and that accounted to a very great extent for the influx of the American farmers from the Northern States. Such men were expert wheat growers and found they could no longer grow "No. 1 hard" in the States, and were going into Canada to grow it. Those men made some of the finest citizens, and were glad to become British subjects. Many of them were returning Canadians. With regard to transportation, a new element had entered into the matter by the building of the Georgian Bay Canal. The route had been surveyed, and he believed the Government had almost decided to start it in the near future. It would run from a point east of Sault St. Marie, northerly to a town called North Bay, and then down the river past Ottawa to Montreal. In the opinion of one of the masters of transportation in the United States, Mr. James Hill, the President of the Great Northern Railway, when the Georgian Bay Canal was built it would drain the freight from the whole of the North Central States as far west as Dacota, so that the wheat instead of passing through the great lakes and the Erie Canal would flow north to the Georgian Bay Canal and thus transfer an enormous amount of traffic in wheat to Canada. That was the opinion of Mr. Hill expressed in a lecture before the Canadian Club of Ottawa. With regard to investments several were very prominent. The first was the application of water-power to electric development both for light and power. There was a huge amount of water-power in Canada that was employing and would employ a very large amount of capital. Another profitable industry was the preparation of pulp wood. The demand for pulp was constantly rising, the States taking large quantities. Recently a number of New York capitalists had acquired 100 square miles of pulp forests in Newfoundland, and he thought Lord Northcliffe had also acquired considerable holdings there. In New Brunswick, Nova Scotia, Quebec, and Ontario there were large areas of pulp wood waiting for the saw. Another investment was the silver mines of Cobalt in Northern Ontario, one of the greatest silver fields in the world. These would repay careful investigation. Then there was the need of money in the West. He had written to a friend of his in the West and asked him to tell him the present condition of finance in Alberta, and in reply it was said that there were exceptional opportunities for the investment of outside capital, and capitalists were just beginning to have their eyes opened to the fact that money could be readily invested there in absolutely safe securities bearing 8, 9, or even 10 per cent. interest; that those who had realised the fact were reaping large profits; that during the past ten years the writer had invested for people living in England and Eastern Canada about 100,000 dollars, most of that money having been lent to farmers at 8 or 9 per cent., and secured by a first mortgage on land, and in no case had the amount of the loan been greater than 50 per cent. of the sum which the farm would realise at a forced sale; and that of all the moneys entrusted to him not one dollar had been lost either of principal or interest. That was a splendid example, seeing that some of the investments were made ten years ago. The writer of that letter was a personal friend of his, and he was sure that everything he said was perfectly true.

Mr. F. B. VROOMAN (of Victoria, B.C.) paid a tribute to the work of Mr. Smith in Canada, especially in connection with the emigration department. He himself had travelled throughout the length and breadth of Canada, and had taken pains to look into the economical resources of the country. It was a marvellous portion of the Empire, and so attractive to him that he had not only invested money n the country, but had invested his family and himself, and established a home, in Victoria on the Pacific coast. He had done that for several reasons; first, one felt in getting into a country like that that one was in the game—in one of the biggest games being played by the Anglo-Saxon race to-day or any other race. He had seen wheat growing on the Brick Farm on Peace River the finest he had ever seen, and similar to that mentioned by Mr. Ross, which Mr. Brick took to the World's Fair to get the first prize. With

the settlement of the country and ploughing of the ground, the vast West was pushing the frost line north at the rate of about a township a year. The Peace River country was much more attractive than the Manitoba country twenty or thirty years ago when people said that nothing could be grown there on account of the frosts. He had heard about people near Winnipeg and Manitoba who had had to go out in the night and build bonfires all over their farms simply to neutralise the narrow margin between frost and no frost, and possibly save their crops. It was his belief that the country in Northern British Columbia and Northern Alberta, in the Mackenzie and the Peace River country, offered the finest field for settlement and investment. In travelling through Winnipeg a year ago he came to a little place called Davidson, between Regina and Prince Albert, and found a population of 500. Four years before, a young cousin of his, twenty years of age, went up there to see what he could do. He settled down, and bought a lot of ground round the two or three houses that then constituted Davidson, and after four years his investment had paid 52 per cent. on £20,000. Another field for investment was timber, because Canada produced the finest timber in the world. No area of its size had so much timber as Vancouver Island or such good timber. The climate of the Pacific coast near British Columbia was such, that wood which took a hundred years to grow on any part of the American continent could be grown there in forty years. In Victoria there was only an average of three days' frost in the year. From Winnipeg north there were possibilities of a great waterway, and due east from Fort William and Port Arthur there were possibilities of another great waterway. During the last few weeks of President Roosevelt's administration, representatives from Canada, Mexico, and the United States met in Washington, and all agreed to work together for the economic development of the North American continent, and that fact would have a great deal to do with the development of Western Canada, and in making safe the investments there. There was also a possibility of a waterway by way of Hudson's Bay to England. In fact, everything connected with the future of Canada was not only a source of hope but promised a source of sound safe investment.

Mr. Reginald Enock, F.R.G.S., wished to lay stress on the more Imperial side of the subject. Up to the present the possibility of investment of capital had been considered solely from the point of view of the investor and paying of dividends; but he thought it would be possible to make use in some practical way of millions of square miles of territory for the millions of poor out-of-work people existing in Great Britain to-day. He thought it might be possible by some practical methods to form Imperial companies working on a company basis to take up some of the magnificent resources of Canada and organise them on such a basis that they might be utilised by those members of the British Empire who were at present wandering workless about the streets of great cities, putting them to work and establishing new industrial centres in the Dominion. It seemed to him that the Empire did not appear to belong to the people. For instance, to whom did the enormous territory of Canada belong? Did it belong to the five or six million people who lived there, to the enterprising Americans or Russians who were going there, or to whom? He thought it should be considered to belong to every British citizen, and, therefore, some workable method should be provided whereby every British citizen, head of a family, who required it should be allotted some tangible share of Empire, and should be helped to make use of it. Mr. Enock said he spoke as a traveller and engineer who had spent many years in North and South America, and Canada, and who had given study to the matter of Imperial land development.

Mr. T. R. Clougher thought a debt of gratitude was owing to the Society for the opportunities it gave to people to realise the great resources of the Empire, and as an outsider he wished to bear a tribute to the Society. He thought there was a great and neglected field for British capital in the lack of enterprise in British manufacturers not seeking to do business in Canada. In 1868 there were imported from Great Britain into Canada goods to the value of 35,000,000 dollars, and from the United State manufactured articles to the amount of 22,000,00 dollars. In 1888, when tariff reform was introduce in Canada, the imports from Great Britain had onl grown to 35,000,000 dollars, while the imports fro the United States had grown to 46,000,000 dollar In 1908 the imports from Great Britain had grown t 98,000,000 dollars, while those from the United Stat had increased to 202,000,000 dollars, and this was i spite of the fact that Canada had given to Gre Britain a preferential tariff of 33⅓ per cent. If th manufacturers of Great Britain had not been ente prising enough to occupy the field they were blame for the unemployed in this country and n the Dominion of Canada. Canada was waiting f English goods, preferring them. Canada, in fac wanted English goods so badly that she was pr pared to give 33⅓ per cent. preference, and thought the manufacturers of Great Britain shou realise that Canada offered such a magnifice field for their enterprise. Two years ago speaking to the head of a large manufactur concern, established in 1774, he was told do not know just for the moment what is bei done in Canada, but I will call the gentlem in charge of that Department." That gentlem said, "I am sorry I cannot tell you just h we stand in Canadian matters; many years a we established a branch in Australia and we managing all our Colonial business from our A tralian house." Again, he had heard Canada abu by a gentleman, who said, "We have been striving

do business in Canada for a number of years. We have had a branch house in St. John's, Newfoundland, for nine years."

The CHAIRMAN, in moving a vote of thanks to Mr. Smith for his paper, expressed the hope that the British manufacturer would wake up, and that British trade with Canada under future and more favourable conditions would increase even in a more striking manner than it had increased since Canada gave a preference of $33\frac{1}{3}$ per cent.

Sir WESTBY PERCEVAL, K.C.M.G. (Chairman of the Colonial Section) seconded the vote of thanks, and said the paper fulfilled the object of the Colonial Section, to place reliable information before the public on subjects connected with Greater Britain. He thought Mr. Smith's paper was certainly a very good sample of the useful work done by the Royal Society of Arts. As an Australasian he heartily congratulated Canada, and rejoiced in the progress she had made, and was making, and as a resident in Great Britain, connected with various financial institutions, he was happy to testify that Canada was rapidly gaining the goodwill of investors in this country. Canada was one of the few countries where there was now no income tax, and those who were looking about to find a place where they could evade the super-tax, could not do better than invest their capital in Canada, and allow their dividends to remain in that country for further investment.

Mr. OBED SMITH, in reply, counted it a peculiar honour not only to be able to visit from time to time the meetings of the Section, but to have an opportunity himself of giving expression to his own opinions. He agreed with one of the speakers that the Royal Society of Arts was entitled to the thanks of many for the advantages afforded by its meetings. He thanked Lord Hindlip for occupying the chair, because he knew that his lordship was greatly interested in Canada.

Mr. E. T. Scammell writes :—

Mr. Obed Smith's paper was excellent and opportune. At the same time, I felt, as I listened to it, that what he said for Canada might and should be said for Australia andfor some of our other Oversea States, for in all of these there is a great and increasing need for the investment of British capital.

One of the most striking points of the paper was that in which he showed that Americans are not only taking up great areas of land in the Dominion, but are seeking to get control of Canadian industrials. The list of American manufacturers who have established factories "inside the tariff wall," which is given in the appendix, is worthy of careful note to the manufacturers of the United Kingdom. A similar operation is also going on in Australia, though to a far less degree than in Canada. But it is a significant fact which should not be lost sight of in this country.

Mr. Ben H. Morgan, in the report upon his visit to Australasia and Canada last year, dealt also with this matter, and showed the necessity of the British manufacturer giving some attention to it, if he would keep his hold upon Colonial trade. It is not the question whether our home trade will be interfered with. That is already been done, and the interference will become more extensive as time goes on. The question is whether we are prepared to take our share in the flow of business which these oversea countries of ours are offering, or whether we shall leave it to others. It will be useless for us to mourn the loss when it becomes acute. What is needed is to face the situation now, and for the British manufacturer to get his foot in as soon as possible.

NITROGEN FROM THE AIR.

In connection with Mr. Eyde's paper on this subject, and as supplementing the information it contains, it may be interesting to mention that a paper was read by Professor Bernthsen, before the Congress of Applied Chemistry, on the fixation of atmospheric nitrogen. He stated that "the great importance attaching to the possibility of the fixation of atmospheric nitrogen had, several years ago, been recognised in the Badische Anilin und Soda Fabrik, and after the task of manufacturing indigo on a commercial scale had been brought to a successful conclusion in 1897, special attention was paid to this new problem at the instigation of the managing director, Heinrich von Brunck. As the result of these labours, Otto Schonherr succeeded in 1905, after eight years' work, in discovering and, with the assistance of the engineer, Hessberger, in working out a process of producing an electric arc-flame of a new form, and he was thus enabled to solve the problem in a manner presenting considerable advantages over the method of Birkeland and Eyde. The new process and method was not a mere modification of their process, but differed fundamentally from it. Whereas Birkeland and Eyde caused the electric discharge to burn in a strong magnetic field, and thus spread it out in the shape of a flat more or less circular disc, Schonherr dispensed entirely with magnets and magnetic fields, and produced his arc inside an iron tube of comparatively small diameter, at the same time passing the air through the tube, and thus bringing it into contact with the arc. An agreement had been entered into with the company exploiting the Birkeland and Eyde patents in Norway, and two new companies have been formed, with capitals of 16,000,000 kronen and 18,000,000 kronen respectively, to develop water power, and to erect works for manufacture of nitrates by the new process. Considerable quantities of 'air-saltpetre' would shortly be put on the market, and probably, within a few years, the annual output would reach 100,000 tons."

THE MEXICAN SHRIMP INDUSTRY.

At the village of Pueblo Viego, situated by the Laguna de Pueblo Viejo, about four miles from Tampico, is centered one of the oldest and most interesting of Mexican industries. Here from March to December, the natives gather the "camarones" or shrimp, which abound in the brackish waters of the lake, and in a primitive manner, cook, dry, and prepare them for market. These famous fishing grounds comprise a group of beds of the narrow water passages of the laguna lying between the numerous small islands, and adjacent to the village. They are directly under the Mexican Federal authorities, and contain ninety-two "pesqueros," or trap-like enclosures, that are being worked. These enclosures are V-shaped, and constructed of bamboo poles, well driven in, between which a mat is interwoven, composed of palm leaves, extending from the bottom to the surface of the water, and to within a few feet of the shore at either end. The lake is connected by canal and the Panuco River, with the Gulf of Mexico, from which the salt water is derived, and which the shrimps follow in the course of the tides. They are caught in traps at the outgoing tide, when it is but a simple matter of gathering with a dip net, and conveying them by canoes to the village. On March 1st each year, the names of all applicants for concessions are brought before the collector of the port of Tampico, who directs the lottery held at the Custom-house for the purpose of designating the locations to be given out. The American Vice-Consul at Tampico says that as many numbers as there are applicants, are made out and placed in a revolving receptacle, and the pesqueros allotted the fishermen according to the different numbers selected. Each location is numbered, and the concession is good for one year, or until the next drawing takes place. Thus a man never knows one year just where he will be placed the next. As quickly as possible after gathering the shrimps are carried to the cooking sheds and placed, two bushels at a time, in a large copper kettle, wherein over a primitive Mexican oven, they are boiled in a solution composed of eight parts of water and six parts of salt for a period of fifteen minutes. After removal they are spread over a large cemented enclosure, exposed to the sun, and allowed to dry for half a day. The remaining water in the kettle is boiled away, and the salt recovered for future use. The shrimps are then packed in sacks of four arrovas' (one hundred pounds) capacity, carried by canoe to Tampico and re-shipped to Vera Cruz, where an excellent market is maintained for the fish. There are gathered and prepared for shipment one hundred and fifty tons of shrimps, annually valued at £4,000. Most of them being consumed in the home markets, although an effort is now being made to introduce them into the United States. Canning has been attempted, but with rather indifferent results, and practically the entire production is sold in the dried state.

HOME INDUSTRIES.

The Coal Industry.—The fears expressed when the Coal Miners' (Eight Hours) Bill was being considered by Parliament seem likely to be justified by events. The Act comes into force (outside Northumberland and Durham) on July 1, and in Wales it threatens to bring about a strike, because in Wales the coal masters have notified the termination of the present wages agreement as soon as the Act comes into operation. The Welsh miners refuse to accept any reduction in wages for working a smaller number of hours per day. The Coal Owners' Association contend that the passing of the Eight Hours' Act in itself terminates the existing agreement and brings to an end the present Conciliation Board. Eminent counsel, whose opinion has been taken by the masters, say that this is the correct interpretation of the Act; equally eminent counsel whose opinion has been taken by the men are of the contrary opinion. As regards Yorkshire Derbyshire, and the chief Midland centres, no great friction or disturbance is anticipated, but difficulties in adjusting present arrangements with the requirements of the Act may arise even in districts where the eight hours' system is now in practical operation In not a few districts there are many of the men and boys over sixteen years of age who are underground ten, eleven, and as many as twelve hours out of the twenty-four. Wherever such hours prevail it is obvious that the operation of the Act will effect a great economic change. For the Act is not confined to preventing more than eight hours' work in the mine but prevents any man (with certain exceptions in the case of officials, furnace men, &c.) from remaining in any sense more than eight hours underground in one day. Now eight hours from bank to bank means when deduction is made for the time from proceeding between the bottom of the shaft and the coal face, for meal time and rest times, not more than seven and in some cases not even as much as six hours of actual hewing. Nor is it only the hewers of coal whose hours underground are restricted, but also all the men who work the underground trolleys, and haulage and winding gear. New roads, additional winding machinery and shafts, double shifts, may keep up the output, but only by increasing the cost of production. And if working expenses are increased the price of coal must increase in corresponding degree, and if the price is raised wages must be raised also since miners' wages are regulated by price. There is, indeed, a theory, held by many supporters of the Act that the men will work better in the shorter day and turn out more per hour in eight hours than at present they do in nine or ten hours, but that is not the opinion of those most competent to judge, and there is nothing to show that it is the opinion of the men themselves. It is difficult to avoid the conclusion that, whatever merits the Act may have in other directions, it will increase the cost of coal. Some experts say it will add 5s. a ton to the cost; others are content to put the increase at 2s. a ton; ev

assuming that it is only 1s. the effect may be very serious.

The Effect of Enhanced Coal Prices.—A rise in the cost of output might seriously affect our coal export trade, which year by year has to face more formidable competition, for this increase in the cost of output, due to the Eight Hours Act, affects British coal alone. The cost of production of the coal of our competitors is not affected. Then there are the other great industries whose prosperity is largely dependent on the cost of coal. Take the railway industry. Lord Claud Hamilton speaks with authority on such matters, and he has stated that an increase of 1s. per ton in coal means an increase of £803,000 per annum in the coal bills of the British railway companies. Mr. Bonar Law, an expert in iron, told the House of Commons that an increase of even ninepence per ton on the price of coal would mean an addition of 4s. per ton on the price of steel. It was demonstrated to Mr. Russell Rea's Committee that the proportion which coal bears to the working of steamers ranges from 25 to 30 per cent. in the case of tramps, from 40 to 45 per cent. in the case of mail steamers, and to nearly 50 per cent. in the case of very large and fast steamers. The outlook is disturbing.

Small Holdings.—A good deal of dissatisfaction is expressed at the slow operation of the Small Holdings and Allotments Act of 1908 by those who are eager to see a large increase in *petite culture*, and it is charged against the County Councils that they are lukewarm, or even hostile, in their attitude towards the Act. It is alleged, among other things, that County Councils are charging prohibitive prices for the holdings provided by them, with the object of making the scheme of small holdings a failure. It is true that the price paid for the small holding is often, perhaps generally, excessive, but it does not follow that the Council is to be blamed. In the first place, landowners, as a rule, are not eager to sell, which means that, unless compulsion is to be used, to which the Councils are naturally in many cases averse, a good price must be offered for the land. Then the Board of Agriculture will not approve any scheme which makes it likely that a loss would be incurred in its working; indeed, the Board insists upon a substantial margin being provided for such expenses as management, &c., even as much as from 20 to 30 per cent., insistance that may be explained by the fact that if the Board approves a scheme, and it turns out in the actual working on the wrong side, it is held liable to bear half the annual loss. The terms of rental are too onerous. The rent the tenant is required to pay is based upon a percentage of the cost of the land and its equipment, plus the amount of the annual sinking fund charge, on account of the repayment of the principal money borrowed by the Council. The result is that at the end of the term of years within which the Council are to repay the capital cost of the land, &c., the tenants will have bought from the Council the entire holding. This is surely unfair to the present tenant, who ought not to be asked to pay for the holding itself in addition to a fair rent for it. If the cost of equipping the land with new buildings is added, it is impossible for a County Council, under the Act as it stands, to rent to small holders as cheaply as they can obtain holdings from a private landlord who is willing to arrange small holdings upon his estate, and is content, as many are, with a return of from 2 to 3 per cent.

A Spurt in Shipbuilding.—There is something like a slight spurt in shipbuilding, although the state of the freight market suggests the urgent necessity of restricting the output of new steamers. It seems to be thought by the more enterprising of the current contractors for new steamers that a great expansion of the world's trade is about to be seen, and that it will be to their advantage to anticipate it. It is probable that there will be a great improvement in freights before long, but only if the output of new steamers is restricted. Yet week after week contracts are being concluded for new boats. Some come under the "liner" head; others are to fill up gaps due to navigation, &c., in cargo-carrying fleets; while in some instances the orders have been for tonnage for which there seems no present justification. And now the addition of even a few new steamers means a large quantity of tonnage. In the past boats averaged 1,500 tons, 2,000 tons, or 2,500 tons, and the addition to tonnage was comparatively small, but new steamers run into 5,000, 6,000, 7,000 tons, and a few very large new steamers tell seriously on the position.

Insurance Reform.—The text has now been issued of the Assurance Companies' Bill, promised some time ago by the President of the Board of Tradé, and intended to amend the law of insurance so as to protect the public from "wild cat" schemes. Its main provisions are—(1) The extension to companies carrying on fire and accident insurance business of the laws relating to life assurance companies, subject to appropriate modifications; (2) to bring under the same laws the businesses of bond investment companies, which in return for small subscriptions contract to pay a lump sum at some future date, and which frequently hold out the prospect of a loan in the meantime to be applied to the purchase of a house; and (3) the amendment of the Life Assurance Companies Acts, so as to place foreign companies in the same position as British companies with which they compete, by providing that all companies, wherever registered, shall deposit £20,000 with the Board of Trade. The Bill also simplifies the procedure by which large collecting societies may convert themselves into industrial assurance companies. The new provisions in respect of foreign life offices doing business in this country are founded on the report of the House of Lords' Committee of 1906. Offices

transacting business outside the United Kingdom, whether British or foreign, are required to provide details as to premiums, claims, &c., outside the United Kingdom, as to assets specially deposited under local laws outside the United Kingdom, and as to any separate valuations required under local laws. This provision will enable any intending policy-holder to see what funds are already hypothecated to meet liabilities outside the United Kingdom, and whether these liabilities are estimated on a more stringent basis than the standard one adopted in the return to the Board of Trade. It may be expected that the clauses of the Bill which apply to classes of insurance business other than life, while open to criticism on points of detail, will be generally approved.

OBITUARY.

Harry J. Molloy, M.I.Mech.E., Assoc. M.Inst.C.E. — By the death of Mr. Harry J. Molloy, which occurred from malaria, at Hassan, on March 3rd, the Government of Mysore have lost a valuable servant. Born in 1865, Mr. Molloy entered this service in 1890 as a temporary assistant-engineer on the Bangalore-Hundupur Railway, then in process of construction. Being confirmed in the service in 1895, he worked as assistant-engineer in various departments, including railways, irrigation, bridges, roads, water-supply, &c., until 1903, when he was appointed Officiating Executive Engineer in the Nadur district. This is a malarial region, and here he first contracted the disease to which, after numerous attacks, he succumbed. Mr. Molloy became a Member of the Society of Arts in 1899.

QUESTIONS AND ANSWERS.

NOTICES TO CORRESPONDENTS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

Cattle Food from Wood Cellulose.— I understand some French chemists have developed a process for making a cattle food from wood cellulose. Can any one give me particulars?—Dugald Scott.

White Lead and White Lead Paint.— I am in search of information bearing on the manufacture of white lead and white lead paint. I want to know —(1) The most recent practice of the manufacturers in this country; and (2) the best text-book on the subject.—R. M.

Difference between Cupolas and Domes.— What is the essential difference between a cupola and a dome? This sounds a trivial question at first sight, but I cannot obtain a satisfactory answer by consulting "the usual books of reference." My desire for a definition arises from the fact that I have been called to task for referring to the "cupola" of a certain building when it is alleged I should have said "dome;" but, on consulting several architects as to how far we may properly use each term, I have received the most extraordinarily divergent replies. According to the dictionaries the terms are interchangeable, but you surely could not call the dome of St. Paul's a cupola?—St. Pancras.

ANSWERS.

Papin's Digester (see p. 444).—Denis Papin's digester attracted much notice when it was first shown before the Royal Society, and many references to it are to be found in the books of that society. Evelyn, in his "Diary," under date April 12th, 1682, gives a description of a supper attended by Fellows of the Royal Society, at which all the food, "both fish and flesh," was dressed in these digesters, "by which the hardest bones of beefe itself, and mutton, were made as soft as cheese without water or other liquor, and with less than eight ounces of coales, producing an incredible quantity of gravy; and for close of all, a jelly made of the bones of beefe itself, the best for clearness and good relish, and the most delicious that I had ever seen or tasted. We eat pike and other fish bones and all without impediment; but nothing exceeded the pigeons, which tasted just as if bak'd in a pie, all these being stew'd in their own juice, without any addition of water save what swam about the digestor, as *in balneo*; the natural juice of all these provisions acting on the grosser substances, reduced the hardest bones to tenderness." Evelyn concludes: "This philosophical supper caused much mirth amongst us, and exceedingly pleased all the company. I sent a glass of the jelly to my wife, to the reproach of all that the ladies ever made of their best hartshorn." The Hon. Robert Boyle published a later description of the Digester in the Second Continuation of his "Physico-Mechanical Experiments" (1680), in which he translates the name Digester as *Balneum Mariæ*. Papin himself published in 1681, with the permission of the Royal Society, "A new Digester or Engine for softening Bones. By Denys Papin, M.D., Fellow of the Royal Society." In 1687 he published "A Continuation of the New Digester of Bones." The author says that the first improvement he made of the

Digester "was when the King commanded me to make one for his Laboratory.".

The origin of the name *Bain Marie* (Balneum Mariæ) has not been satisfactorily accounted for by Littré. Ducange supposes that it was evolved from a supposed writer of a known alchemical work, whose name was Maria. Whatever may be the truth about this, it seems clear that the name has come down to us from the mediæval alchemical literature. (See Berthelot, "Histoire de l'Alchimie," &c.)—H. B. WHEATLEY.

STAINED GLASS WINDOWS (see p. 597).—It is somewhat difficult to say anything decisive in reply to this question, if only for the reason that before doing so one ought to make quite sure one has in mind the same glass that is referred to. Speaking generally, however, there is a good deal of literary evidence to warrant one in supposing that cobalt was introduced into glass making about the time referred to, and that as it was probably used in an impure state in the first instance, such a colour would be made with it. Although Bruchmüller (*Der Kobaltbergrau und die Blaufarbenwerke in Sachsen*) considers that the use of cobalt in the arts dates so far back as to be lost in obscurity, there seems very little doubt that the peculiar properties of the cobalt ores of Saxony were only recognised about the end of the fifteenth century. Up to that time they had been regarded as useless: the very name cobalt, in fact, emphasises this, signifying, as it does, an evil spirit, and being derived from the fact that the old miners when they came across cobalt ores in searching for iron considered they had been enchanted and made useless by the evil spirits of the mine. Many writers have tried to prove that the pigmentary properties of the cobalt compounds were known to the Egyptians, but so far as I am aware there is no practical, as distinguished from literary, evidence in support of this: that is to say (although people have juggled with the words "lapphre" and "sapphire" in an attempt to prove that their use by Theopilus and earlier writers must have signified cobalt) no one has ever found cobalt on chemical analysis of any specimen of glass or pottery earlier than the fifteenth century—no one, that is, that I have been able to discover. I would not like to make this statement positively, because such records have a way of getting into the most unlikely places and escaping one's notice. We do know for certain, however, that the cobalt ores in Saxony began to be explored at the close of the fifteenth century, and that Schurer commenced to manufacture smalt about 1520 in Bohemia, whence its use spread to Italy and Holland, and became the subject of an English patent in the reign of James I. This, then, would account for its use in connection with stained glass at this time and not before, presuming that the colour of the particular glass referred to is due to cobalt. But one must bear in mind that the introduction of a fresh tint in glass is not necessarily due to the use of a new colouring agent—the composition of the white glass in which any colouring oxide is dissolved, has a considerable influence on the resulting colour, and it was at the period referred to that the use of soda in glass making, in place of potash, began to be introduced, and the composition of window glass gradually reverted from the highly basic material of the Middle Ages back to the soda-lime glass used by the Romans, and forgotten for a thousand years. One would expect as a result of this to find new tints appearing in the windows, but of course this is all conjecture—the only practical way of settling the matter would be to make careful complete analyses of glasses of different periods, but this, being a lengthy and costly business, nobody cares to do.—N. H.

NOTES ON BOOKS.

THE ARCHITECTURE OF THE RENAISSANCE IN ITALY. By William J. Anderson, A.R.I.B.A. London: B. T. Batsford. 12s. 6d. net.

When this book was first published in 1896, it at once took its place as the standard work on the subject with which it dealt. A second edition was called for in 1898, a third shortly afterwards, and now a fourth and enlarged edition has been prepared by Mr. Arthur Stratton, Lecturer on Architecture at King's College, London. The success of the book may be traced to three causes: the excellence of the text, for the late Mr. Anderson was a master of his subject, and he wrote with a cultured and scholarly pen; the excellence of the illustrations, to which many valuable collotypes have been added in the present edition; and the fact that it supplied the student for the first time at moderate cost with a clear and comprehensive view of the whole course of the Renaissance in Italian architecture. The book is too well known to call for a descriptive notice here. Suffice it to say that the task of revising Mr. Anderson's work could not have been entrusted to a more competent editor than Mr. Stratton: while he has been well advised not to alter or increase the subject matter to any large extent, he has added many photographs and measured drawings which have been selected with the greatest care and are admirably reproduced by Mr. Batsford.

GENERAL NOTES.

WHITE PHOSPHORUS IN MATCHES.—In the annual report of the Chief Inspector of Factories and Workshops (Mr. Arthur Whitelegge), for the year 1908, which has just been issued, attention is drawn to the fact that the White Phosphorus Matches Prohibition Act, 1908, will come into force on January 1st next. After that date white phosphorus matches may not be made and imported, and after January 1st, 1911, may not be offered or exposed

or held for sale. The Board of Trade are empowered to grant licenses for the use of any process, patented before the date of the Act, for making matches (not intended to strike only on a specially prepared surface) without the use of phosphorus, and to fix the terms. Meanwhile all the match factories in the United Kingdom, with one notable exception, remained free from any case of necrosis, as in the three previous years; but in that one factory a further case occurred in 1908, and two other attacks have been reported in the first quarter of 1909. The disuse of white phosphorus in this industry will render obsolete the special rules established in 1899. . . . . It may be that for a time cases of necrosis will still occur among persons who in the past have been exposed to phosphorus, but the exposure will cease with 1909, and in some at least of the works, including that in which all the recent cases have occurred, arrangements are being made to anticipate the appointed date.

BRITISH TRADE IN KERMAN, SOUTH PERSIA.—A private correspondent writing under date of 1st April from Kerman in the British sphere of Central Persia, states that that city is just taking the place of Yezd as the chief distributing centre of the country. A sample room containing specimens of the British and Indian goods most in demand in that part of Persia and capable of being supplied through Bunder Abbas, has been started by the British Consul and placed in charge of a British merchant. The Consul, Major Ducat, is very anxious to make English traders aware what an exceptional opportunity there is for capturing a profitable market which otherwise must fall into the hands of the Russians. The chief desideratum is the improvement of the road communication and the establishment of a regular and reliable transport service between Kerman and the Indian Ocean at Bunder Abbas. In the meantime the Russians are pouring in their goods from the north *viâ* Meshed. Two New York firms have established American agents in Kerman, a third has a Europeanised Armenian acting for them in the surrounding districts, and a fourth firm talk of establishing a regular agent in the city. The chief article of export is of course the far-famed Persian carpets, but there are mineral and other resources waiting to be exploited if the road difficulties are once effectually grappled with. So far as the carpet trade is concerned the new agents are already cutting out the Tabriz Turk buyers.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, JUNE 15...Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 8 p.m. 1. Mr. E. R. Taylor, "The National and International Conservation of Water for Power." 2. Mr. W. Fielding, "The Formation of Silicon Sulphide in the Desulphurisation of Iron." 3. Mr. Ch. A. Keller, "A Contribution to the Study of Electric Furnaces as Applied to the Manufacture of Iron and Steel." 4. Mr. Gustave Gin, "Automatically Circulating Furnaces of the Gin Type for the Electrical Production of Steel."

Asiatic, 22, Albemarle-street, W., 4 p.m. Dr. E. Denison Ross, "A Unique Arabic MS. containing the History of Gujarat under Muhammadan Rule down to the Time of Akbar."

Statistical, 9, Adelphi-terrace, W.C., 4½ p.m. Annual General Meeting. Mr. G. Paish, "Great Britain's Capital Investments in Foreign Lands."

WEDNESDAY, JUNE 16...National Indian Association (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 4½ p.m. Mr. R. F. Chisholm, "The Taj Mahal, Agra."

Meteorological, 70, Victoria-street, S.W., 4½ p.m. 1. Mr. R. C. Mossman, "The Interdiurnal Variability of Temperature in Antarctic and Sub-antarctic Regions." 2. Dr. W. Schmidt and Mr. E. Gold, "Testing of Registering Balloon Apparatus at Low Temperatures." 3. Mr. L. C. W. Bonacina, "A Plea for the Use of Freely-Exposed Thermometers in Addition to Sheltered Ones."

Geological, Burlington-house, W., 8 p.m. 1. Mr. J. A. Douglas, "The Carboniferous Limestone of County Clare." 2. Dr. J. E. Marr and G. W. Fearnsides, "The Howgill Fells and their Topography." 3. Mr. L. Glauert, "A New Species of *Sthenurus*." 4. Mr. D. S. Watson, (*a*) "Some Reptilian Remains from the Trias of Lossiemouth." (*b*) "Some Reptilian Tracks from the Trias of Runcorn (Cheshire)." (*c*) "The Anatomy of *Lepidophloios laricinus*, Sternb."

Microscopical, 20, Hanover-square, W., 8 p.m. Exhibition by Dr. J. A. Brayton Hicks of the Better-known Tropical Parasites.

THURSDAY, JUNE 17...Linnean, Burlington-house, W., 8 p.m. 1. Mr. J. G. O. Tepper, "The Growth of a Species of Battarea." 2. Sir John Murray, "The Deposits in the Indian Ocean." 3. Mr. L. A. Borradaile, "The 'Sealark' Perseidea, Steoropidea, and Reptantia." 4. Mr. F. A. Potts, "The 'Sealark' Polychæta." (Part II.) 5. Mr. T. Bainbrigge Fletcher, "The 'Sealark' Lepidoptera." 6. Dr. H. Christ, "New Species of Malesian and Philippine Forns." 7. Messrs. T. A. Sprague and J. Hutchinson, "The African Species of Triumfetta. Linn." 8. Mr. A. W. Hill, "The Acaulescent Species of Malvastrum, A. Gray." Exhibition by Mr. Clement Reid of Plants in Britain introduced by the Romans.

Chemical, Burlington-house, 8½ p.m. 1. Mr. S. P. U. Pickering, "The Carbonate of Copper and the Cupricarbonates." 2. Mr. F. L. Pyman, "Isoquinoline Derivatives. Part I. Oxidation of Laudanosine." 3. Messrs. J. T. Hewitt and W. Thomas, "The Colour and Constitution of Azo-Compounds." 4. Messrs. H. J. H. Fenton and W. A. R. Wilks, "Isoiminazolone." 5. Messrs. H. J. H. Fenton and F. Robinson, "Homologues of Furfural." 6. Messrs. T. M. Lowry and C. H. Desch, "Studies of Dynamic Isomerism. Part IX. The Relationship between Absorption Spectra and Isomeric Change. Absorption Spectra of Sulphonic Derivatives of Camphor." 7. Mr. B. Flürscheim, "The Relation between the Strength of Acids and Bases and Quantitative Distribution of Affinity in the Molecule." Part II. 8. Mr. H. D. Dakin, "The Oxidation of Hydroxy-Derivatives of Benzaldehyde and Acetophenone." 9. Messrs E. de B. Barnett and S. Smiles, "The Intramolecular Rearrangement of Diphenylamine *ortho* Sulphoxides."

FRIDAY, JUNE 18...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. Henry Savage Landor, "A Recent Visit to the Panama Canal."

Journal of the Royal Society of Arts.

No. 2,952. VOL. LVII.

FRIDAY, JUNE 18, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-fifth Annual General Meeting for the purpose of receiving the Council's Report and Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held in accordance with the By-laws on Wednesday, 30th June, at 4 p.m.

(By Order of the Council),
HENRY TRUEMAN WOOD,
Secretary.

ALBERT MEDAL.

The Council of the Society, with the approval of His Royal Highness the President, have awarded the Albert Medal of the Society for the current year to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

MEDALS FOR PAPERS.

The Council have awarded the Society's Silver Medal to the following readers of Papers during the Session 1908-9 :—

At the Ordinary Meetings :—

To Mr. G. ALBERT SMITH, for his paper on "Kinematography in Natural Colours."

To Mr. HENRY C. BREWER, for his paper on "Gothic Art in Spain."

To Monsieur YVES GUYOT, for his paper on "The Commercial Relations of France and Great Britain."

To Mr. GEORGE HUBBARD, for his paper on "Dew-ponds."

To Mr. WALTER ROSENHAIN, for his paper on "The Application of the Microscope to the Study of Metals."

To Mr. GABRIEL GORDON CLEATHER, for his paper on "The Musical Aspect of Drums."

To Mr. C. REGINALD ENOCK, for his paper on "The Resources of the Peruvian Andes and the Amazon."

To Mr. PERCY A. WELLS, for his paper on "English Furniture Design and Construction."

To Mr. ARTHUR JOHN BARRY, for his paper on "Railway Development in China."

To Herr SAM EYDE, for his paper on "The Manufacture of Nitrates from the Atmosphere by the Electric Arc."

In the Indian Section :—

To Mr. DOUGLAS DEWAR, for his paper on "The Birds of India."

To Mr. ARTHUR ANTHONY MACDONELL (Boden Professor of Sanskrit, Oxford), for his paper on "The Buddhist and Hindu Architecture of India.'

To Mr. SELWYN HOWE FREMANTLE, for his paper on "The Problem of Indian Labour Supply."

To Mr. KRISHNA GOVINDA GUPTA (Member of the Council of India), for his paper on "Some Phases of Hinduism."

To Mr. CECIL L. BURNS (Principal, Bombay School of Art), for his paper on "The Functions of Schools of Art in India."

In the Colonial Section .—

To the HON. CHARLES GIDEON MURRAY, for his paper on "The Road to South African Union."

Of recent years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers :—In the Ordinary Meetings the papers by Sir W. Martin Conway, on "The Goldfields of Eastern Peru and Bolivia," and by Mr. Archibald R. Colquhoun, on "Bosnia and Herzegovina ; " in the Colonial

Section, the papers by Mr. Albert E. Humphries, on "The Production of Wheat in the British Empire," and by Mr. John Ferguson, C.M.G., on "Ceylon: its Industries and Material Progress."

The Council, however, desire to express their high appreciation of these papers by thanking their authors for them.

The brilliant lecture delivered, under the Aldred Trust, by Professor Dendy, was not considered to be eligible for a Medal, though it occupied one of the Ordinary Meetings.

EXAMINATIONS.

The results of the Advanced Examinations (Stage III.) have been published, and copies have been sent to all Centres for distribution to Candidates.

The results of the Intermediate Examinations (Stage II.) will be published during July, and those of the Elementary (Stage I.) early in August.

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the galleries of the Natural History Museum, South Kensington, on Tuesday evening, June 29th, from 9 p.m. to 12.

The Reception, by Sir William H. White, K.C B., F.R.S., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Engineers, in the Central Hall, commencing at 9 o'clock.

An Instrumental Concert by the "Red Band," under the direction of Mr. Thomas Batty, will be given in the Fish Gallery from 9.15 till 10.15 p.m., and from 10.30 till 11.30 p.m.

A Gramophone and Auxetophone Concert, under the direction of the Gramophone Company, will be given in the Shell Gallery at intervals from 9.15 p.m.

The following portions of the Museum will be open:—

The Central Hall, containing cases of specimens illustrating Mimicry; adaptation of colour to surrounding conditions; protective resemblance, &c.; also specimens illustrating the food of Fishes, and the life-history of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque deep-sea fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), the Lemon-sole (case 30), &c.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum.

Visitors travelling by District Railway (or other underground railways in connection therewith) will be allowed free use of the Company's Subway, which leads from the South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These tickets have now been issued. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by members, at the price of 5s. each, if purchased before the day of the Conversazione. On that date the price will be 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the Musical and other arrangements will be given in the Programmes which will be distributed on the evening of the Conversazione.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

Thursday afternoon, May 27th; PROFESSOR SIR HUBERT VON HERKOMER, C.V.O., D.C.L., R.A., in the chair.

The CHAIRMAN said he had had some information from independent sources as to the good work Mr. Burns had done in Bombay, and was especially interested in him because he was one of his earliest students at Bushey. He had heard that when Mr. Burns was appointed in 1899 he found the School of Art not in the best of conditions, but owing to his energy and skill it was now one of the most successful in India, with departments for textiles, pottery, and design, and workshops for plastic and metal working. He had done excellent service in training drawing masters and revising the system of teaching entirely on sound principles, and the school was popular and efficient.

The paper read was—

THE FUNCTIONS OF SCHOOLS OF ART IN INDIA.

By CECIL L. BURNS,
Principal of the Bombay School of Art.

In considering the functions of schools of art in India, and offering suggestions regarding the broad lines upon which, in my opinion, they can successfully cope with the peculiar problems they are intended to solve, I must premise my remarks by saying that my practical experience has been confined to the work performed by the School of Art in Bombay city and Western India.

Of course, like other officers whose time and duties are devoted to assisting the progress of the country in a special direction, I have made it my business to see as far as possible the work carried on in other schools of art, and have studied the reports, dealing with my subject, issued by the Governments of other provinces. The knowledge I have thus gained, leads me to believe that although slight variations may occur in the local conditions elsewhere than in Bombay and Western India, the problems with which I shall deal this afternoon are fairly general throughout India.

To discuss the whole of the functions of the schools of art would, I fear, take up more time than I have at my disposal this afternoon. I, therefore, propose to limit the scope of my remarks to the relation they have to, and are capable of exercising upon, the applied arts of the country. Although this limitation should not entirely exclude some reference to the study of architecture, sculpture and painting, pursued in the schools, for these arts are but the development and higher expression of kindred crafts, it is unfortunately true that in India, as in Europe, the teaching of those branches of art has become separated in modern practice from the teaching of the crafts. I shall, therefore, have to leave what are known as the Fine Arts unconsidered except where they directly relate to the industries of India.

The limitation I propose, however, coincides with the declared purpose of Government in founding the schools of art, which was to preserve from decay and to improve the crafts of the country. In order to give you some idea of the nature of the task the schools have been called upon to perform, and the peculiar difficulties of that task, it will be necessary for me to notice briefly the revolutionary changes in the conditions under which the crafts of India are now carried on as compared with those prevailing up to the year 1857, when the schools of art were first instituted. These changed conditions appear to me to lie at the very root of the admitted decadence of the ancient crafts of India, and so far from being ignored must form the basis of any attempts to revive their former prosperity.

THE FORMER ISOLATION OE INDIA.

Up to the year 1850, India, from an artistic stand-point, was almost entirely isolated from the rest of the world. In fact, she was more isolated during the eighteenth and early part of the nineteenth centuries than was the case during the sixteenth and seventeenth centuries, when the Moghul emperors were carrying out their great building schemes. We know that for the elaborate structures erected by Akbar, Jehangir, and Shan Jehan, huge armies, which included foreign, as well as native workmen, were employed, while the splendour of the courts of those emperors attracted an almost equal number of other craftsmen, chiefly goldsmiths, carvers, and brocade weavers. The foreign craftsmen undoubtedly exercised a very considerable influence upon the style of the buildings erected at that period, especially with regard to their decorations, and it was the introduction of new ideas by these foreigners, allied to the special aptitude for particular craft work on the part of the Indian workmen, due to the caste system, which resulted in

producing the best schools of art India has yet seen, and the golden age of Indian artistic work.

The wars and resultant social disturbance accompanying the decline of the Moghul rule changed everything. The great works of a former age were stopped, and the army of foreign and native craftsmen was disbanded. A certain number of native artisans were doubtless retained about the decadent Court at Delhi, or took service with the chiefs and rajas who ruled as independent sovereigns the former Moghul provinces, but as warfare was almost continuous, it is certain that the encouragement given to these craftsmen was spasmodic, while the foreigners either returned to their homes or dying were not replaced.

From the East India Company the indigenous artistic craftsmen received even less support than from the rulers who immediately preceded it. The early exports from India to Europe were mainly of raw or partially worked products, and when the Company ceased to be only traders, and acquired territory, both directors and officers were too busy with the task of consolidating their rule within the recently acquired provinces and in repelling attacks from their neighbours, to afford the time to foster and encourage the arts of the country.

The artistic craftsmen employed by the princes whose kingdoms were occupied by the East India Company in the later end of the eighteenth and early part of the nineteenth centuries, again either migrated to the Courts of those native chiefs who still ruled their own kingdoms, or they established themselves in small towns and villages, and had to depend for support upon the uncertain patronage of the local public.

The Freedom of the Indian Craftsmen from Foreign Competition.

The isolation of these towns, not only from Europe, but from the rest of India, gave the workers in them a practical monopoly in their local markets. The artistic work was in many instances carried on by the descendants of the men who had helped to build, or decorate, the palaces and mosques of the Moghuls, but the tradition of that great period had died out. Methods of work had become purely rule-of-thumb ones, and although these were often full of ingenuity, and marvels of patient industry, the processes the workmen employed were devoid of that basis of scientific knowledge which alone could lead to improvement. The patterns they used, gradually became few in number, were traditional in character, and were suited only to meet the local requirements or the tastes of a small section of the community.

Being without literary education, and therefore ignorant of what the rest of the world had done or was doing, being cut off from contact with workmen engaged in similar crafts in other parts of India, and being without ambition, the workmen stagnated. Methods remained unimproved, and from much copying their designs became lifeless, while the craftsmen, from never attempting to devise new patterns, lost whatever power of original thinking they may have formerly possessed.

They were doubtless poor, according to European standards, but as they were free from all outside competition, they were well able to live by their work. Their few and simple implements were admirably adapted to the isolated condition in which both craftsman and client lived. This simplicity enabled most of the craftsmen to carry their trades upon their backs. There is, for instance, something delightfully artless in the methods of the district potter, who is still to be met with in country districts, carrying his light wooden wheel upon his back. When he arrives at a village, he sets himself down on the outskirts, weights his wheel with the same local clay he has previously dug, in an adjacent field, for his pottery, sets it turning upon an iron spindle which he has carried with him in his belt, and which he fixes vertically in the ground. He then proceeds to turn out pots for the village. These he bakes in a rough earthen kiln, and when they are fired, and disposed of, the potter chips the dried earth from off his wheel, restores the spindle to his belt, and with the wheel on his back tramps off to repeat the operation at the next village.

The pottery thus made is cheap, and serves its purpose, and as the forms are those naturally taken by clay thrown upon a potter's wheel, they are often beautiful, while as no attempt is made to give finish to the surface after they have dried, they retain the charm inseparable from the impress of the human hand. Such a system, however, is unlikely to lead to improved methods of work, or to the eventual production of wares comparable to those issuing from the kilns of Meissen, Sèvres, or Staffordshire

Most of the other handicraft work of India formerly possessed a distinctive character, due

to the isolation of the workmen, but from the internal causes before specified it deteriorated in quality, though despite its failings it still provided a living to the craftsmen.

Attempts to Revive the Ancient Crafts by Establishing Art Schools.

While this process of decadence had been going on, Europeans of cultivated taste and learning, most of whom belonged to one or other of the services of the East India Company, had studied assiduously the ancient religions, the archæology, and the art of the country. The beauty and distinctive character of the buildings and craft-work of a former period had aroused their enthusiasm. Comparison between the old work and the modern revealed the deterioration that had taken place in the latter, and archæologists began to advocate steps to arrest this decay.

At the same time, practical Indian business men who had had the opportunity of studying the superior mechanical quality of the craft-work of Europe, and its organised methods of production and distribution, and of comparing it with the rougher work of the isolated craftsmen of India, recognised the necessity of adopting improved methods on the part of the latter, if they were to retain their position in their own markets, which were beginning to be invaded from the West.

About the middle of the last century there was thus a consensus of opinion in favour of some steps being taken toward the improvement of Indian craft-work, and the movement in England at that time, which resulted in the establishment of schools of art throughout this country, provided the opportunity for all those interested in the desired revival, to press upon Government the establishment of similar schools in India. Thanks to the persuasive writing of eminent servants of the Company and the munificent initiative of the first Sir Jamsetjee Jeejeebhai, the distinctly chilly attitude of the Court of Directors was at length transformed into one of tepid acquiescence, and schools of art on a very modest scale were started in Madras and Bombay.

A fundamental difference regarding their functions existed in the minds of the two sections of Indian opinion whose combined efforts brought about the establishment of the schools of art. Those whom for want of a better term I may call the archæologists pinned their faith in a possible revival of the crafts upon a strict adherence to the ancient traditional types of design and practice, and those whom I will style the practical men based their hopes of improvement upon the introduction of European methods while leaving the question of design unconsidered. There was one element necessary to the realisation of the aims of both advocates of reforms, which neither seems to have completely recognised. This was that success depended upon the continued isolation of India from competition with the art-workers of Europe. To accomplish a revival of Indian art upon purely traditional lines, in the absence of a compelling movement from within the country, which did not exist, the art of the West had to be excluded. Isolation and time were also required to improve the methods of the Indian craftsmen, if they were to be in a position to compete on equal terms with the better equipped and organised workmen of the West.

Failure due to Changed Conditions.

The opening of the Suez Canal was the death-blow to the realisation of the hopes of both sections. India from an artistic point of view quickly became and has since remained a suburb of Paris and London, as she is from an industrial point of view the suburb of Manchester and Birmingham.

Forms of art previously unknown have by means of imported reproductions and original works become familiar to the people of India, while the local markets have been invaded by artistic craft-work made by the organised workshops of Europe, before the Indian craftsmen have had time to improve their methods.

The great increase of wealth due to the extension of Indian trade has also brought about a change in the style of living among the wealthy classes in India, many of whose individual members have been educated in this country and still more of whom have visited England. These have become familiar with and have adopted Western ways and have furnished their houses in European style. Every season also sees in England a greater number of the members of the families of the ruling princes of India, and their capture is an object of ambition by the tradesmen of the metropolis, whose goods are found in every palace in India. As a typical instance of the extent to which this change of taste has grown, I may mention that out of over two hundred presents given upon the occasion of a recent wedding of a well-to-do Indian gentleman and lady, I could find only sixteen that

were of Indian origin, the remainder being of European manufacture or copied from European patterns by Indian craftsmen.

It is also a curious instance of the effect politics may have upon art, that settled government under British rule has had a distinct influence upon the style of the jewellery and personal ornaments worn in India at the present day as compared with those of fifty or even thirty years ago. In the old days, articles of gold and silver were regarded chiefly in the light of portable property, easily hidden, and reconvertible into money. They were, therefore, valued more on account of the weight of precious metal they contained than for the beauty and elaborate nature of their workmanship. The massive proportions and primitive character of the old Indian jewellery and metal work was due to this consideration. Of late years, owing to the greater security of personal property a stable form of government has afforded, the old reasons for weighty articles of personal adornment have ceased, and the lighter and more delicate styles of workmanship of Europe have begun to supersede the ancient types. Imported articles fill the shops in the bazaars of the large cities, and are pushing their way into the country towns, where they are copied by the native artisans.

Another result of settled government tending toward the introduction of alien ideas is the alteration that has taken place in the style of the buildings being erected throughout the country.

Coincident with and as a result of increased wealth extraordinary activity has occurred in the building trades in India. Great improvement schemes are in progress in Bombay which involve the rebuilding of large sections of the city, and the occupation of every vacant plot by new structures. During the short period of nine years I have seen the business quarter of the city almost transformed and commercial firms rehoused in palatial offices, fitted and appointed in a manner that would do credit to any city in Europe. Large and costly public buildings have already been put up or are in course of erection, which, so far as their dimensions are concerned, have scarcely been seen in India before, and the same activity is to be witnessed in almost every considerable town in the country.

The style of these buildings, however, is rarely, if ever, purely Indian or even Eastern in character, but in the majority of instances is either European or of some composite style of architecture. The arguments for and against the adoption of European styles in modern Indian buildings were ably stated in a paper read before this Society by Mr. T. R. Smith in 1873, and the question has since been fully considered in connection with the erection of the Queen Victoria Memorial building in Calcutta. It is too large a subject to discuss this evening, but the decision to adopt European styles in Government and other public buildings is one decidedly germane to our subject. As all the decorative arts have originated from and are dependent upon the style of the architecture they are intended to enrich, the decision referred to must exercise a powerful influence upon the practice in all the crafts allied to the building trade, and through them upon the teaching in the schools of art.

Thus we find at the present day that India has ceased to be isolated, and that potent forces both within and without have been and are at work to modify the indigenous character of her art by that of Europe. Her craftsmen have, without preparation, found themselves confronted by the keen competition of the rest of the world, in place of the comparative monopoly they formerly enjoyed in their own local markets under the fostering care of Rajas and religious communities. They have been called upon to supply patrons with articles of alien origin and use in place of those of traditional types, and to provide the decorative details to buildings concerning the architectural styles of which they are entirely ignorant as regards their origin, growth, or the principles upon which those styles are based or have been developed.

How have the Indian craftsmen met the changed conditions? Their ancient art had decayed from internal causes before the European incursion made the situation as acute as it has since become. The invasion caught them before they had been equipped to meet it, and they have been forced to struggle against extinction by the cheapening of their handiwork until it has lost nearly every characteristic which made it valuable. In the interior of the country, where the pressure is not so acutely felt, the artistic craftsmen painfully compete with their rivals of the West by their superior knowledge of purely local requirements and by the cheapness of their mode of living. In the larger centres they attempt to meet the demand for articles of European origin, by copying the patterns to be

found in the trade catalogues of English and German firms. Such catalogues are certainly not the kind of text-books we would recommend a student to consult, and the result is that the Indian craftsmen copy, as a rule, the ordinary commercial patterns, instead of the most artistic Europe has produced. I well recollect, soon after landing in India, asking the master in the wrought-iron class in the Bombay School of Art workshops, to furnish me with a design for a standard lamp. The man was a very capable smith—though rather too much addicted to riveting in place of welding his ironwork—and a man of fair intelligence. He promptly produced from a cupboard an ancient and well-thumbed copy of a catalogue issued by a North of England firm of cast-iron railing manufacturers in the year 1867, when the Applied Arts were certainly not at their best in England, and it was from this treasure-house of artistic suggestion that he proposed seeking inspiration for his design. Outside his workshop was growing a plant, whose stems and foliage were so admirably adapted to treatment in metal, that I was at first under the impression that it had been purposely planted with that object, but when I drew his attention to its suitability for the proposed design, he regarded the suggestion as some form of subtle pleasantry on the part of the "Sahib." It took a considerable time to persuade him that a natural form could in any way be utilised for the purposes of his craft, and still longer to convince him that his pattern-book was more valuable as fuel than as a work of reference—though it is scarcely necessary to add that he read no more in that book during that or any subsequent day.

I may instance Indian silverwork, an industry both widespread and full of distinctive character in the past, as one that has deteriorated seriously from internal causes and outside influences. Even in the design and workmanship of articles of traditional shape and use, it is almost impossible now to obtain examples of pure design and good proportion. Much of this want of harmony is due to the fact that in the silversmiths' workshops in many of the large cities, craftsmen from different parts of India and Burma are employed and work side by side. Each of these workmen knows a few traditional designs which he has inherited from his father, but none of them have ever been trained to understand the principles upon which all design is based. When cut off from the safe anchorage of tradition these craftsmen are completely adrift, but none are adverse to borrowing the designs of his neighbour. The only guidance and superintendence the workmen receive is from the owner of the shop, who is not an artist but a tradesman. It is not surprising, therefore, that in the case of indigenous articles, the decorative details have become very mixed; while when an article of alien origin is being made a single specimen often includes a shape copied from a British or German trade catalogue, embellished with mouldings taken from half a dozen different sources, stands upon feet of French design, is encircled by a Poona hunting scene or by Burmese gods, and if it be a tea-pot will have an old English handle and an elephant's trunk for a spout—and the unfortunate thing about the whole is that the designer and makers of this anachronism are not only absolutely unconscious of its failings, but are both proud and pleased with their ingenuity in getting so much variety into a single work. Whatever objections may be urged against the good taste of the products of the organised factories of Birmingham and Sheffield, fault cannot be found with them on the score of their mechanical finish or their efficiency in serving the purpose for which they are intended, while the British hall-mark upon them is a guarantee that the silver used is of a trustworthy standard of purity. So much, I regret to say, cannot be said for the majority of the Indian silver articles of a similar type. There is a roughness about the edges, a tendency to stand upon three legs, a "wobbly" action about the hinges, which evince an almost indecent alacrity in parting from the lid or body of the article, and a proneness to pour from anywhere except the spouts of their teapots, that the owner of many an Indian silver tea set must have noticed as falling below the standard in these respects of the British-made article. As regards the quality of the silver used I fear that in many instances the metal is more remarkable for the skill with which the greatest amount of the baser metals has been added to the alloy without affecting its colour, than as an ideal standard of purity. Much of the deterioration of Indian silverwork is also undoubtedly due to the determination of the "globe-trotter" to get something he considers characteristically Indian. He knows that Indian work is supposed to be elaborate, and he, therefore, requires the surface of any article he purchases to be covered with ornament, but he refuses to pay the price at which the elaborately finished

hand-work of the past was produced. He gets, therefore, a roughly made article, covered with hastily executed ornament in a metal that looks like silver, but which no one will venture to submit to the test of Goldsmiths' Hall on his return to England.

The European visitor to India has thus been the means of encouraging the faults most noticeable in the Indian silversmiths, namely, their want of care and accuracy in finishing their work, and it is in consequence of these faults that the reputation of Indian silverwork has been brought to its present low point in the estimation of connoisseurs and collectors in Europe.

In most of the other artistic crafts of India the same struggle is to be seen of imperfectly educated and inadequately-equipped workmen competing against the highly-organised and educated craftsmen of the West in their own markets, and driven from all those foreign ones which they formerly supplied, not in consequence of the action of hostile tariffs, but by reason of their lack of capacity to adapt themselves to altered demands and changed conditions. I may instance the case of the weavers in the small town of Thana, near Bombay. Within living memory there were 6,000 of these men employed in the production of finely-woven fabrics for the English market. The trade has been completely lost in consequence of a change of fashion in England, and the incapacity of the craftsmen to design any patterns except the few traditional ones they had inherited, and the number of weavers in the town is now reduced to five or six, who can scarcely exist by supplying a limited local demand. The same want of knowledge of design prevents the patient and skilful brocade workers of Western and Central India from reaping the advantage their cheap living should give them over the English and French hand weavers of costly brocades, for which there is now a steady demand in Europe and America. They also have consequently to be content with a bare existence obtained from a small local demand, while the shops in the European quarters and the bazaars in the native cities are stocked with fabrics of European design or of excellent reproductions of Indian patterns made in England, France and Germany.

A striking instance of the extinction of a budding artistic industry due entirely to the want of scientific training occurred in the case of the pottery attached to the Bombay School of Art. Many people will remember this pottery, which was carried on commercially by the late Mr. Terry, who for some time was the Principal of this School of Art in its early days. The style of the pots produced was that of the old Sind tile work, and potters from Multan were brought down to do the work. This ware had a considerable vogue in England, as some of the pieces were beautiful both in shape and colour, but as the body was extremely porous and the glaze soft and irregular, the percentage of breakages in transit was, despite careful packing, extremely large. Another drawback due to these faults was that the jars refused to hold water. This latter failing led to rather unfortunate results occasionally, and I well remember some time before I went to India witnessing the disastrous effect not only upon a very fine specimen of this ware, but incidentally upon a grand piano and its silk cover, occasioned by the misplaced confidence of a servant in the capacity of a Bombay jar to hold flowers and water. I was calling on the proud possessor of the pot, and when I was shown into the drawing-room, the flowers placed in the pot an hour or two before were looking very sad; most of the pattern and glaze originally on the vase had fallen, and was scattered about upon the silk piano cover; while the water, obeying the laws of gravity, had found a resting-place in the interior of the grand piano.

Despite its failings, however, the sale of this pottery in England, reached the respectable figure of £6,000 or £7,000 annually, but as the merchant in Bombay who exported it recently informed me, the demand suddenly ceased. When he made inquiries as to the cause, he was told by his agent in London that the Bombay pottery had been entirely superseded by pottery imported from Japan, which was harder both in body and glaze, was not subject to any of the drawbacks I have mentioned, and was quite as cheap. When my informant suggested that the mechanical defects of the Bombay pottery might be remedied he was told that the Sind potters only knew the rule of thumb methods they had inherited, and knew nothing of the scientific basis of their industry. This statement I can well believe, for whenever I have suggested improvements in the technique of their work to these men. improvements based either upon notes made by me during a six months' stay in the Potteries of Staffordshire about 25 years ago, or such as I had gained from books, or such as were dictated by common-sense, I was

always met with the complaisant admission that, although my suggestions might be all right, the method proposed was the English one, which the potter did not pretend to understand. The result was that an important artistic industry capable of employing designers, modellers, and painters trained in the School of Art, was stamped out at its very beginning by the superior knowledge of its mechanical details on the part of foreigners.

I have dwelt somewhat fully upon the artistic failings and the economic decay of the modern craft-workers of India, due firstly to causes found within the country, and hastened by competition from without, not from any wish to paint the situation in colours of an unnecessarily sombre hue, nor from any want of faith in the capacity of the Indian craftsman to do in the future as excellent and characteristic work as he has given to the world in the past, but because it is absolutely necessary to realise the present unfortunate position of the craftsman and the altered conditions under which he had to work, to understand why the Schools of Art have been unable to fulfil the purpose for which they were founded fifty years ago, and because a complete recognition of these changed conditions must, in my opinion, form the basis of the teaching given in the Schools of Art to the craftsmen of the future if artistic or economic improvement is to be attained.

The Work of the Schools of Art in the Past.

I come now to the question of what the Schools of Art have done in the past, and once again I must point out that my knowledge is chiefly confined to the work of the Bombay School of Art in that city and in Western India. Firstly, however, I must ask you to consider the extremely difficult nature of the task they have been set to perform, when compared with that allotted to similar schools in England and on the Continent. To begin with, in the whole of British India, with its population of close upon two hundred millions, there are only four Schools of Art, each separated from its nearest neighbour by a space of nine hundred miles. Only one of these schools, that at Bombay, has ever had continuously upon its staff two Europeans specially trained and competent to direct its policy and studies. The whole burden of the direction of each of the other three schools has, except for very short periods, been thrown upon the shoulders of a single European. The only expert assistance available in the craft schools has been supplied by workmen taken from the bazaars, scarcely any of whom have been able to read English. The great bulk have, therefore, been cut off from the possibility of consulting modern text-books dealing with their particular crafts, which they have never been trained to teach.

The principals of the schools have had many purely administrative duties allotted to them quite outside those connected with the schools, such as the holding of examinations, the direction of museums, the organisation of exhibitions, and the writing of industrial monographs.

When, therefore, you consider the inadequate number of the Schools of Art for the task imposed upon them, the isolation of their directors from *confrères* engaged in similar work, the nature of the expert assistance they have had, and I may add the character of the climate in which they have had to work, and contrast these with the thirty Schools of Art to be found within a six-mile radius of this hall, carried on by an aggregate staff of nearly 400 professors and instructors, each a highly trained practitioner in his special subject, which he is also competent to teach; adding to this that all are able to give their undivided attention to the objects for which the schools were founded, and that the schools are supported by public grants which if proposed by the head of a School of Art in India would lead to a medical inquiry into the state of his mind, you will not be inclined, I am sure, to criticise harshly the labours of such devoted and enthusiastic workers in the past as Mr. Lockwood Kipling and Mr. John Griffiths if, despite the utmost they could accomplish, they found it impossible to prevent the crafts of India from reaching the plight I have shown you they are now in. They bore the heat and burden of the early days, when even in England the policy of Schools of Art was in its experimental stage, and when in India such schools were often looked upon as little better than expensive fads forced upon Government, and bearing little or no relation to the practical business of the country. They had to struggle through periods of alternate neglect and encouragement, according to the individual tastes of succeeding Governors and Lieutenant-Governors, not to mention Directors of Public Instruction, which made continuous development impossible, and were at one time faced with the threat of the complete extinction of their work. We who have succeeded to their labours are filled with admiration at the

devotion and persistence our predecessors displayed, and if in the light of experience some of us are of the opinion that other methods are required to meet the vastly changed conditions, this does not lessen by one jot our appreciation of the many services they rendered to the cause of art and art-teaching in India.

In fact, the task was a hopeless one from the very start, unless, as I have before observed, India could have remained isolated from the rest of the world. From their commencement, the Schools of Art failed to attract the sons of working craftsmen, who were unable to perceive the advantage a knowledge of drawing would be to them in their daily work. The classes were, therefore, attended principally by boys and young men, who had taken advantage of the literary education supplied by Government. These youths belonged, in many instances, to castes that had supplied craftsmen, but they had no intention of following the crafts of their fathers. They looked for employment in one of the professions, or under Government, and with very few exceptions disdained to work with their hands. The artistic industries gained nothing, therefore, from the schools during the early years; but in other directions considerable use was made of these more highly-educated students. Mr. Griffiths was able to establish a training school for drawing teachers, and by means of the pupils passing through it to introduce the study of drawing into every high school, and most of the aided schools in the Bombay Presidency. He created a body of trained teachers of drawing, which eventually enabled Government to make that subject a compulsory one in the majority of the schools of the Presidency, and this has brought to light many students possessing aptitude for artistic work.

Under his supervision, the drawing, painting, and architectural students of the school have copied most of the finest monuments of the past in Western India, and the library of the School of Art in Bombay now contains sketches, models and measured drawings of so complete a character, that it would be quite possible to reproduce them, should the originals be destroyed by accident, or fall into decay.

That decay may possibly be the fate of some of the most interesting artistic records of the ancient civilisation of India, even in these days of active interest in the archæology of the country, and energetic endeavour to preserve its ancient monuments, was strikingly brought to my notice when I recently visited the cave temples of Ajunta. The valuable paintings upon the walls of these caves are darkened and otherwise injured to a degree that renders large portions of them undecipherable. Not one of them but shows the effects of time and neglect upon its surface, and unless some determined effort is quickly made to preserve them from further decay the careful and complete copies made by students of the Bombay School of Art under Mr. Griffiths's superintendence will be the only record future generations will have of these unique works.

Every Government department, as well as the drawing-offices attached to municipalities, is to a great extent indebted to the Schools of Art for the supply of the trained draughtsmen they employ, while openings for educated youths have been found through the school training, in the offices and studios of practising architects, engineers, and photographers throughout the country.

Although the course of events has been too powerful for the Schools of Art to succeed in preserving the crafts of the country from European influence, they have through their craft schools given a training in drawing to many hundreds of young craftsmen, such as it would have been impossible for them to have otherwise received, and by insisting upon careful workmanship, and by reproducing only the best examples of the works of the past, they have set a standard to the bazaars of India which would have been the means of saving modern Indian craftwork from the principal failings I have noticed, but for the fierce commercial competition to which the working craftsmen have been subjected.

The work of our predecessors in India needs therefore no apology or defence from us who have succeeded to and benefited by their labours. With inadequate means they successfully strove in many directions to reawaken the latent artistic spirit of her people, and they created that interest in Art among the educated class of the country, upon which future progress must depend.

They did the same kind of pioneer work that was performed by those who conducted and controlled the Schools of Art in England for the first thirty years of their existence, which cleared the path for the remarkable advance in artistic education we now see throughout this country.

The Future Policy of the Schools of Art.

Having attempted to give such a sketch of the present condition of the crafts of India as is necessary to understand the problems the Schools of Art are faced with, and to offer what I feel to be but an inadequate account of the work those schools have done in the past, I will proceed to deal with the more important question of what the future policy and function of the schools should be.

During the nine years in which I have studied the subject upon the spot I have been forced unwillingly to discard many of the prejudices with which I landed in India. With many hundreds of youths passing through the School of Art, whose personal careers and future usefulness to the country depend in a great measure upon the instruction the school affords, it has been necessary to put aside one's own preconceived ideas and artistic predilections and look at the hard facts of the case as they are and not as one would wish them to be. What those facts are I have already described, and their consideration has led me slowly and unwillingly to the conclusion that although the artistic capacity of the people of India is present, the ancient craftwork of India is as dead as the art of the Greeks or as that of the Renaissance in Europe.

Like the magnificent works of the Greek and Renaissance artists, those of ancient and medieval India must always serve as types and examples full of inspiration to students. Progress, however, can no more be achieved by limiting the art-workers of India of to-day to the servile copying of those masterpieces, than it could have been if the artists and designers of Europe had been only allowed to reproduce the masterpieces of Greece or Italy. On the contrary, the copying of the old designs has been the cause of the mental atrophy which distinguishes modern Indian craftwork from that of the Mughals, and I feel convinced that the artistic regeneration as well as the economic salvation of the craftsmen of India will never be brought about until they follow the example of their *confrères* in Europe. They should regard the great works of the past as inspiring standards of taste and achievement, but must cease to sponge upon their ancestors for artistic ideas. They must be trained to understand the principles upon which their ancestors built up their designs, and apply those principles to the inexhaustible storehouse Nature offers to the designer in India. Then I believe we shall have living and characteristic work consistent in every part in place of the dead copies or anachronisms we now see.

At the same time, the Indian craftsmen must adopt the same efficient mechanical and scientific methods of production as are employed by their Western rivals if they are to preserve their markets from invasion or are to capture new ones, while the rising generation of artworkers of every class and degree must be trained to meet the requirements of their clients as efficiently as the students in Schools of Art in Europe if they are to take advantage of the new fields for profitable employment the increasing wealth of India now offers them in the decorative arts. India must do for her artistic industries what Europe did long ago and what Japan has rcently done, transform them from an aggregation of isolated craftsmen to organised and skilfully directed combinations of workmen.

How can these changes be brought about, and what part can the schools take in them? Firstly, the teaching in the Schools of Art may be made less antiquarian in its character, and the students, while not ignoring the past, may be brought into closer touch with Nature, and be taught the manner in which natural forms may be applied to design. Steps in this direction have already been taken in Bombay, with results that have confirmed me in my belief that the decadence of Indian craftwork is not due to any weakening of the special aptitude the people of India have always shown for the decorative arts, but is owing to the fact that they had ceased to go to Nature for their inspiration.

I have ventured to place on the walls of this hall specimens of the original drawings and designs done by young students in the design classes of the Bombay School of Art, and drawing classes of the High Schools under a system recently introduced. Many of these students are mere children, and very few have been studying for more than two or at most three years. The drawings and designs have not been specially selected for this exhibition, but as will be seen by the marks inscribed on many of the drawings, they have been taken from the drawing-books used in the ordinary course of study.

The valuable point about these drawings and designs is in my estimation that each one is the original outcome of an individual student's own ingenuity. The drawings of simple objects and Indian plant forms have been made from Nature and from memory. A few problems in geometry have been learnt, and by arranging

the natural forms on a geometrical basis designs have been developed. As different flowers have been used by each student, or different geometrical bases have been used for the same flower, different designs have resulted. The memory drawings, which represent objects in the pupils' homes, were all done within fifteen minutes, and certainly appear to me to exhibit extraordinary facility when compared with the same kind of work done by European boys of a similar age. They show that the power of drawing from memory, which is a gift only occasionally met with in Europe, is almost universal in the East wherever the power to draw at all is present.

I have no desire to exaggerate the importance of these drawings, which are merely school studies; but I think they give reasonable assurance that the Indian designers only have to be shown how to use their minds to produce as vital work in the future as in the past.

It is useless to train designers if the objects they decorate are of such faulty construction or material as to render their labours valueless. I have already described how the Bombay pottery was driven out of the English market by the superior technical qualities of the pottery from Japan; while there is no pottery made in India at the present time that for quality can compete with the porcelain and tile work of Europe, which is being imported into India in large quantities, and the same superiority is to be seen in the materials used in nearly all the artistic crafts.

With the object of bringing up the materials and processes employed by the artistic craftsmen of India to the level of the practice in Europe, a technical laboratory has recently been attached to the School of Art in Bombay, and a well-equipped building has been erected in which four European experts will enquire into and improve the technical processes employed by the Indian potters, weavers, calico-printers, metal-workers and cabinet-makers. One of these experts is already at work, and as the appointments of all have received the sanction of the Secretary of State, I trust before very long all four will be conducting research work calculated to remove the worst of the faults now noticeable in the materials the Indian craftsmen employ.

Attached to this laboratory will be a normal school for craft teachers, in which selected students from the School of Art and its workshops will be trained to take charge of local craft schools as they are gradually established throughout the presidency.

Two steps have thus been taken by the Government through the School of Art in Bombay in the direction of equipping the Indian craftsmen and students of art to meet the competition of the West, but before design students, trained in the School of Art, and technical scholars, trained in the laboratory, can be trusted to superintend commercial undertakings, opportunities must be found for them to gain practical experience in workshops or design rooms where work is carried on under business conditions. In neither the School of Art nor the laboratory can such experience be obtained. The function of the former is to teach and not to engage in business, while the function of the latter is to carry out research work for the benefit of the Applied Arts generally, and to train teachers for the local craft schools. All attempts that have hitherto been made to mix up business with teaching in the Schools of Art in India have proved either educational or business failures. It stands to reason that the sudden intrusion of contract work into the midst of a carefully planned and graduated educational course must destroy its continuity, while any attempt to carry out decorative work by novices learning their trade leads to great waste both of time and material, for the work has to be done several times over, and generally has an unsatisfactory result. Of course, this does not mean that the graduated exercises in the school are to be dry academic studies useless for any purpose when completed, and I have placed a few photographs of work done in the workshops attached to the Bombay school to show that this is not the case, but the execution of such work is a very different thing from that of taking a contract for work that has to be finished in a given time and must be up to a certain standard.

Lack of Opportunities for Practical Training in India, and suggested Remedy.

In England this opportunity for the practical training of art students outside the schools is afforded by the studios and workshops of the large and wealthy firms by whom applied art work is chiefly carried on. These studios and workshops are superintended by designers possessing, in many instances, talent of a very high order, assisted by thoroughly trained and experienced craftsmen. A student engaged in one of these studios or workshops gains a knowledge of design and work it would be impossible for him to acquire in a School of

Art only, though he is able, by the study of advanced drawing and design in the evening classes of the school, to supplement his studio and workshop practice. Thus studio, workshop, and school work together, each supplying what the other lacks, and combine to keep up the numbers of experienced designers and trained craftsmen capable of taking the places of the elder men as they retire, or of providing reliable superintendence for new enterprises as they are started.

As there is an almost unlimited supply of trained designers in England, capitalists investing money in applied art work can, by paying for it, command the services of the best talent in the country. In India, on the contrary, there are scarcely any trained designers at all, and by their absence capitalists are prevented from engaging in business in this direction, while the art students in India are deprived of those opportunities of gaining practical experience enjoyed by the students in England.

It is quite true that an Indian firm might engage the services of an expert European designer to superintend their drawing office, but it is very doubtful if sufficient inducement to leave England could be held out to the best in the profession. Remuneration would have, in any case, to be offered on a scale that would render the commercial success of any such undertaking extremely problematical. To import second-class men, or those who had been failures in England, would be worse than useless; it has already been tried with disastrous results both to the men themselves and the capitalists who have engaged them.

The absence of trained designers in India has in another direction affected the chances of the students of the Schools of Art obtaining remunerative employment. It has reduced the architects to the alternative of either cutting out the greater part of the ornamental portions of their designs which involve artistic work of a high order, or of going to a European firm to supply them. Several instances of the former alternative having been forced upon architects against their inclinations have come under my notice, while in the case of four palaces now being erected in Western and Central India, upon the interior decorations of which a sum of over £20,000 is being spent, every penny laid out upon artistic work will go to European firms and their employees, instead of to the artists of India, because the latter lack the experience necessary to the designing of the work, and no firms can be found in India capable of satisfactorily undertaking its execution.

At the same time, students who have spent years studying in the Schools of Art, and who would be quite able to do this work, if properly directed, are unable to earn an adequate living by their profession after leaving the schools. They, therefore, drift into other occupations, or remain idle, and naturally feel disappointed and discontented at the unsatisfactory position they find themselves in after their long period of study.

How can opportunities of gaining practical experience be provided for the art students of India, and what inducements can be held out to Indian capitalists to engage in applied art work? As is usual in India, I fear Government will have to show the way, and a means exists of doing so through the agency of the Architectural Section of the Public Works Department, at very little extra cost compared with the inestimable value it will be to the art students, and through them to the advancement of the applied arts in India. At the present time, although Government spends many thousands of pounds annually upon the fittings and decorations of new buildings, and upon the repairs and renovation of old ones carried out under the supervision of the Public Works Department, it must be admitted that such work, when done by Indian contractors is, as a rule, greatly below the standard of Europe. In my own bungalow, for instance, I have seen house painters putting on the coats of paint with a rag, instead of brushes, and applying them by means of their feet, instead of their hands—though I do not venture to assert that this is the universal practice of the house painter in India. Neither should I like to state positively that they never take off the old coats before applying the new ones, though I must say I have rarely if ever seen it done. It is undeniable, however, that anybody who knows what good work is, cannot fail to notice the inferiority of the decorative work in modern Indian buildings as compared with that in England and on the Continent, and the same remark applies to the rest of the interior fittings.

To remedy this I suggest that Government should establish a drawing office or studio with a certain number of workshops attached, in which the best decorative work to be placed in public buildings could be designed and made. The whole establishment might be under the control of a small Board consisting

of the Consulting Architect to Government, an Engineer or Accounts Officer of the Public Works Department and the Principal of the School of Art, and should be run on purely business lines.

A trained designer to superintend the work would not at first be required, as most of the designs for details would be supplied by the Consulting Architect, which the staff of the School of Art could see accurately carried out, while the European experts in the technical laboratory would supervise the preparation of the materials used. The staff for both drawing office and workshops would be recruited from the schools of art and their craft schools.

Such an establishment would supply the link which is missing in the educational chain that should join the Schools of Art with the practical craftwork of the country. It would ensure a better standard of work being done in the decoration and fitting of public buildings. It would certainly be the means of introducing new artistic industries into the country, and it would serve as a model to the craftsmen and capitalists of India, and by gradually providing trained designers and technical experts would be the means of inducing these capitalists to engage in industries connected with the applied arts. It would be the means of opening a wider field for the profitable employment of the educated classes, and would secure to the skilled handicraftsman of India a preponderating share of the craftwork that is now being executed abroad.

If for excellent reasons Government already makes it own guns, gun carriages, ammunition and transport wagons, builds its smaller boats and does its own repairs, and if the municipalities and the railway companies find it to their interest to maintain their own drawing offices and workshops, I cannot see any reasonable objection against, but many reasons in favour of Government executing the decorative painting, artistic metal work, cabinet and tile work in public buildings through the medium of a Government drawing office and workshops.

A few contractors may lose contracts they now obtain, and a certain number of unskilled workmen may have to find work in other directions, but against this must be set the fact that Government will have the work done more efficiently as it will be done under skilled supervision, they will be showing the way to both capitalist and craftsman, and they will bring the art schools into touch with the practical work of the country in a manner not seen in India since the time of the Mughals.

The influence such a drawing office and workshops will have upon the teaching in the Schools of Art will be as striking as the effect their establishment will have upon the character of the decoration of the public buildings themselves. With the prospect of profitable employment open to them, intelligent and talented students of every class will join the schools, and their subsequent absorption among the art workers of the country will relieve the overcrowding that is now felt in the other professions. Having definite objects in view the teaching in the schools of art will become more practical, and instead of being tied as they now are to the low level of the bazaar, the craft schools will be forced to train their pupils to fit themselves for employment in a drawing office or workshop carried on upon European lines and under commercial conditions.

It may be reasonably expected that as experienced designers and technical experts become available capitalists will come forward to establish similar studios and workshops. When this happens it will be an easy matter for Government gradually to decrease the output from their own workshops or to hand them over to be carried on by private enterprise. But until these designers and experts have been thorougly trained in practical work, and this is the real root of the whole problem, it appears to me that both in the interest of artistic education and for the economic future of the craft-workers of India, Government should follow the example it has set with regard to the more urgent, but not more important, requirements of the military and naval services and establish such a studio and workshops as I have roughly sketched.

I fear that in the observations and suggestions I have offered this afternoon I have laid myself open to two criticisms, and these I will now answer in anticipation.

The first is that in dealing with the subject of Indian art and art schools I have taken too low and commercial a view of the subject: that art in a school should be treated as an ideal and abstract subject and should be studied apart from such a practical consideration as the possibility or otherwise of art students being able to earn their living after they leave the school; that the value of a School of Art lies in the elevating effect the study of the ideal works of the past has upon its students, and through them upon the

national taste; in short that a School of Art should concern itself solely with what have come to be considered the Fine Arts and should leave the crafts of the country severely alone.

This criticism is based upon the assumption that there is a dividing line between the Fine and Applied Arts, an assumption which gradually came into existence in Europe during the eighteenth century, which brought debasement to the crafts of the early nineteenth century, and has been combated by the best writers and workers since. The greatest painters and sculptors of the past such as Holbein, Dürer, Francia, Cellini and Michael Angelo, as well as many of the finest of the moderns, such as Flaxman, Alfred Stevens, Alfred Gilbert, and, if he will permit me to mention his name, our Chairman this evening, have by their practice proved the falseness of this assumption, and have demonstrated the unity of the arts with the crafts.

Government schools have been founded both in England and India for the special purpose of equipping the craftspeople of each country to meet the competition of their rivals throughout the world.

Recognising the fact that although individual artists may be willing to undergo privations amounting in some instances to actual starvation in the pursuit of an ideal, bodies of craftsmen will cease to follow any occupation which fails to afford them a reasonable living, Governments have fostered the crafts and have for the most part left the teaching of painting and modelling to private enterprise.

The teaching of the Fine Arts has, however, not been altogether excluded from the curriculum in Government schools, but the way to them has been through design and craftwork, and has not been separated from them. In India especially, where painting and sculpture had never been considered except as parts of the decorative scheme of a building, or some other composite work, until the idea was imported from Europe in modern times, it appears to me to be desirable that this order of progression should be maintained in Government schools. If these schools succeed in producing a class of thoroughly well trained designers and craftsmen, who can obtain a sure living by their efforts after leaving the school, they will have performed a valuable function in the State. If among these designers and craftsmen there should be found men of exceptional ability in any direction, opportunity for further study should be available, when their previous studies in design and craftwork will have provided the soundest educational foundation they could have been given. But for a Government school to turn out numbers of indifferent painters and modellers, such as we see coming annually from the private art schools of England, who cannot obtain a living by their work after they leave the school, whose training there unfits them for the service of the Applied Arts and generally for any useful pursuit in life, would not only be an ill service to the State, but would be contrary to the intention with which the schools were founded.

The other criticism of my suggestions will probably be that, if carried out, the ancient character of the Indian crafts will be destroyed. To this I reply that Art never stands still; if it is not progressing it is decaying. For the last hundred and fifty years Indian art has decayed because the craftsmen were content to let their ancestors do their thinking for them, and progress can only be achieved by encouraging them once more to think for themselves, and by teaching them how to embody their thoughts in their work.

The work of the past we all admire was produced by men who thought for themselves and were not content to copy the work of those who preceded them, and it was the outcome of the conditions of the time in which they lived.

Those conditions have now entirely changed and can never be brought back again, but so long as Nature in India offers combinations of form and colour not found in Europe, and so long as the Indian designer imbues those forms with the mental characteristics which separated his art in the past from that of the rest of the world, there can be no danger of Indian art disappearing or of it being dominated as it now is by the art of the West.

DISCUSSION.

The CHAIRMAN (Prof. Sir Hubert von Herkomer) thought the paper was a very practical one, and it seemed to him the gist of it was an appeal to bring a traditional art up to date, not an impossible thing, though a difficult one. To copy merely a traditional art would have no more artistic meaning than to take a cast of a corpse, and a corpse was not a nice thing to live with even as a cast. The tradition once had a vitality, but that vitality lessened and ceased as years went on. It was with man's handiwork as with man's life; Eastern nations, full of romance, talent, and latent power, were in a transitional state, and it was

important that they should get the right help from the Western nations. For that purpose only the best men should be allowed to teach and those men should be adequately paid. Second-rate men were far more mischievous than no men at all. The paper breathed the right spirit; it was based not only on common-sense but on data gathered by the author himself, and he certainly hoped as an old teacher that Mr. Burns's advice would be taken. The great thing appeared to be the need of some central organisation from which branches could be worked, and at the head of that central organisation should be a strong man with unlimited power. Such a man should not have to fight officials, a great drawback to good work not only in India but in this country. He trusted that the common-sense of the paper would be taken to heart by those who had the power to bring it to fruition.

Sir GEORGE BIRDWOOD said that he wished to introduce to the meeting some examples of Indian domestic, and village, and urban art, in demonstration of the truth of his own life-long contention, tacitly contradicted by Mr. Burns, that in all her immemorial historical arts, weaving, pottery, jewelry, carving, &c., India was living India still. He had fought that battle out in official reports, and other publications, from 50 to 60 years ago; and had no wish, in the circumstances of pleasantness and benignity wherein they were there assembled, to fight it over once more in that revered room,—new-enkindling a sleeping fire for the purgation of the self-same heresies twice and thrice again. Strongly as he held his own views on any controverted point, he held to them in the true spirit of a student of the life in which he found himself, well recognising that in confuting the errors of the past we are too often but establishing in the present fresh errors for correction in the future. Moreover, as a matter of grateful consideration towards Mr. Cecil Burns, he would very much prefer to enlarge on the many questions on which they were agreed, than to treat of the few whereon they stood at variance. After coming safely all the distance from Bombay to address them there as he had done that afternoon,—and with so great ability and fulness of experience, and enthusiasm, and distinction,— they must not damp down the true Promethean fire that animates his breast by lavendering him in the "allaying Thames" as it laps past those painted walls! Obviously Mr. Cecil Burns's paper was of unusual interest and value, and exemplary and admirable alike in its accumulation of far brought facts, the clearness of their exposition, the force of their suggestiveness, the significance of the conclusions drawn from them, and the earnestness with which he had urged them on their attention. But for these very reasons it became all the more his duty to demur to Mr. Burns's tendency to regard the traditionary decorative arts of India as dead,—at least as dying,—an assumption he had unhesitatingly to meet by a direct, explicit, and emphatic negative. Mr. Cecil Burns in effect said, and their eminent Chairman expressly said, that the Eastern nations were not in their present state of transition exercising to the full their latent artistic powers; and that it was therefore of great importance that they should get the right help to this end from the Western nations. And again, Mr. Burns said, in so many words, that India must do for her artistic industrials what Europe did long ago, and what Japan has recently done, and transform them from an aggregation of isolated craftsmen into organised and skilfully directed combinations of workmen; and as a step to this end he suggested that the Government of India should establish in various centres a drawing office or studio, with a certain number of workshops attached to it, in which the best decorative work, to be used on public buildings, could be designed and made. The Government would thus, he went on to say, show the way to both capitalists and craftsmen to bring Schools of Art into touch with the practical work of the country in a manner not seen in India since the time of the great Emperors of Delhi. Now those practical recommendations were right enough so far as they went; but they were partial, and, indeed, absolutely disparate, both in their aim and end,—the improvement of the ornamental details on public buildings in India, and of the artistic articles of Indian industry required for exportation to Europe and America: and lop-sided and imperfect also in the means proposed for attaining these results,—the official training of the craftsmen of the great polytechnical cities of India in draughtsmanship,—that is European draughtsmanship of the flowing line; the mastery of which, let him add, would, if exercised in the reproduction of Oriental designs, at one stroke transform them into occidental designs, and be the utter destruction of the Warangal type of Indian carpets, the most classical Oriental type of carpet, not only in India, but anywhere in Asia,—or modern Europe, including America. This disparity of Mr. Cecil Burns's apprehension of the problem before them, and of the solution of it advanced by him, is the fundamental explanation of his undiscriminated notion of the growing failure of the craftsmen of India in artistic sensibility, and in the power to embody their mental and emotional interpretations of nature in the terms of art, as applied to the utilities, amenities, and reverences of the common daily life of their country folk and country. "Toto cœlo"—he separated himself from so despairing a view of the present and the future of the Indian craftsmen; who are to this day, intrinsically, in every respect, capable of sustaining their reputation of the past in its greatest periods, to its highest pitch; any default in their traditionary inspirations and manipulative sleights being observable only where the opportunities for their free and untrammelled exercise are closed to them by the overwhelming and overmastering competitions of Europe and America; and, in an insignificant and utterly negligible proportion, of our Schools of Art,

where these have been, from time to time, degraded from their higher objects, and debased to the status of commercial factories, for the purpose of providing an income out of the penurious pocket of the personally-conducted "globe-trotter" in part repayment of the costs of their maintenance by the State. Mr. Cecil Burns took no account of the hereditary and sacro-sanct craftsmen of India; an omission which, if not absolutely fatal to his pervading polemic, at least vitiated it throughout in its data and its deductions. What this amazing hiatus means may be somewhat measured by the fact, brought out by calculations he (Sir George Birdwood) made from 50 to 60 years ago for the *Bombay Saturday Review*, that the output of the village hand looms of India, for local disposal, could not be fixed at less than the total machinature by Manchester of cotton piece goods for both home and foreign consumption. Still it is the Moloch of Manchester that is the actual menace to the greatest of all the artistic manufactures of India after pottery. It is impossible to estimate the prodigious production of the hand-thrown pottery of the Indian villages. No earthenware pot or pan can be used twice over for cooking food or personal ablution by the twice born castes of India; a rule of ritual that from a timeless past has constituted India the potters' paradise: and it is the shards accumulated, under the operation of this religious custom, in and about the villages of India, that through the ages have gradually upraised their foundations above the level of the surrounding fields and orchards. And so far, he (Sir George Birdwood) had observed no falling away in the productiveness, or the art, either of these rural hand-looms or potters' wheels. And as for the illiteracy of the Indian craftsmen of which Mr. Cecil Burns had complained, they are, as found in the village communities of Western India, the most literary peasantry in the world, not excepting those of France and Scotland (which received most of its "culture" from France and Switzerland), and spend all their evenings in the wrapt enjoyment of recitations from their great national epics, the Ramayana and Mahabharata and the religious and patriotic poems of Tukaram. It is as if our agriculturists and artizans spent their evenings around our parish churches and on our village greens, in popular readings from Shakespeare, Milton, and Swinburne! Mr. Cecil Burns dealt, indeed, only with the nomad craftsmen who have been accustomed from time immemoral to travel over all India and Asia, and Northern Africa, and Southern Europe, to the very confines of France; and who in India are now, under the beneficent influences of the "Pax Britannica," largely represented by the sedentary craftsmen of the bazaars of the great polytechnical cities, such as Bombay, Surat, Ahmedabad, and Baroda; where, however, even these reclaimed wanderers, when they happen to be Hindus, are severely organised in trade unions; and where the sumptuary industries carried on by them, such as embroidery in gold and silver, and jewelry, still flourish as healthfully and serenely, and in as superb and supreme beauty and glory, as ever under the greatest of the Mo(n)gol Emperors of Delhi. They show no more signs of decay in their technique or their artistry, than do the more strictly sacramental, because more directly utilitarian, simple handiworks of the hereditary craftsmen of the democratic villages. It is true that, for the most part, they work in more or less complete isolation; and that may be to their detriment in some respects, for it may bind them too hard and fast to tradition; but it is certainly to their advantage in many ways, not the least being that it prevents their being moved by such sudden changes in fashion as those to which the artistic industries of the West—Europe and America—are exposed, often to their utter disorganisation and lasting degradation, as seen in the inane and crazy "creations" of "*l Art nouveau*." But Mr. Cecil Burns seemed to him to be positively obsessed by the idea of teaching the craftsmen of India,—that is of the great polytechnical cities of India,—to manufacture his handiworks more in the taste and fashion of the "machinations,"—the mere merchandise,—of Europe and America, and in direct competition with them. It is all of a piece, only more "villainously so," with our substituting in the literary education of people of India, Shakespeare and Milton and Swinburne for Valmiki and Dwaipayana [the reputed author of the Mahabharata] and Tukaram:—and of course what we Western Aryas of Europe and America want from India are "Bombay Mangoes," and not "Kentish Pippins,"—while, where there is any demand in India for English apples, it is not for imperfectly acclimatised Apple-johns, withered afore they ripen, but for sacks upon sacks of them, brightly red and green, and green and white in the bite, fresh from the orchards of Kent or Devonshire,—their pips all deeply embrowned to chestnut, propitious for divinations!—and there, indeed, lies a real link of community between "the East that's always Least," and the West that is never at rest. In his (Sir George Birdwood's) own judgment the wisest policy to adopt with the Indian craftsmen was to leave them alone, and severely alone, to pursue in their own markets, rural and urban, the artistic industries in which their excellency had been recognised from the beginnings of the authentic history of the Old World. But if we must exercise ourselves over their education, he saw no objection to providing them with instruction for perfecting them in the mechanical details of their work, the factor in artistic industries in which by universal consent we have hitherto stood preeminent. This is what had been done, within the memory of so many there that afternoon, so successfully by Mr. Chisholm in Madras, Mr. Griffiths in Bombay, Mr. Havell in Calcutta, and John Lockwood Kipling in Lahore. Mr. Cecil Burns also from his first landing on the Island of Bombay approached the Indian craftsmen of the City of Bombay, and of the other polytechnical cities of Western India, in the spirit of

a similar intelligent and sympathetic appreciation of the artistry of their several crafts; and sought to excite in them some sense of the advantage to themselves of putting improved mechanical work, of the various kinds required, into their productions; but he was going too far (Sir George Birdwood said) when he went on, in the paper he had just read, to insist on the Government assuming the position of a capitalist controlling combinations of these urban craftsmen, and turning the Schools of Art into some sort of State factories simply to promote the commercial exploitation of the artistic wares of India in Europe and America. The Government would only lose the money risked on so uncongenial an adventure, Indian art would be more than ever degraded and depraved by it, and another disintegrating blow would be dealt to that democratic caste system, which was the one solid and sound foundation of the social order and security, and peace, and happiness, of the Hindu communities of India. But this was entering into the domains of political economy, and administrative policy, while all he (Sir George Birdwood) was concerned to press home was the fact—and it should be the all-controlling fact—that no one who knows the craftsman of India, rural or urban, as we find him throughout the length and breadth of that immense outstretched peninsula, from "the [Himalaya] Mountains to the Bridge [Adam's]," and from Tatta to Dacca, but must accept him in the artistry of his handiwork—whatever its mechanical defects—as the master art craftsman of the world; who never had a rival but in his brother Aryan craftsman of Hellas, from whom [from about B.C. 250 to A.D. 250] he learnt so much of his higher arts, as architect and sculptor, and the Saracens, all of whose art is Greek art adapted to their religious tenets and social usages [to this day the workers in Arabesques of Egypt are all Greeks]; but who has nothing to learn from any of the art craftsmen of America or Europe, who on their part have much to learn from him, for his art is not the foolish and vulgar expression of the fickle fashion of every idle passing hour as is theirs, but an art nourished in enduring health and strength directly by the Nature, under the chastening discipline of the traditions of three millenniums of unbroken social, literary, artistic, and religious culture: a culture wherein religion, and art, and literature, and the diurnal and annual round of human life, are indissolubly one, and in which he finds the fulness of a spiritual happiness, that carries him serenely past every material menace and misfortune that may befall him: and, wherefore, his (Sir George Birdwood's) prayer from his first knowledge of him had steadfastly been, in the words of Milton, "God stay him in that felicity!"

Sir George Birdwood illustrated these observations by casual examples of Indian art industries of minor denominations, the work of village and urban craftsmen, particularly those engaged in the service of Hindu temples, some of them spontaneous and untaught applications of European materials, such as beads, to immemorial Indian designs; some conventionalised directly from surrounding objects of Nature, the leaves and flowers, and seed vessels of trees of the Western Ghats; some, as the phallic case [resembling the "cista-mystica" of the Phrygians], of the Lingaits of Canara, symbolising universal Nature and the vital energy of Nature, within the limits of a pill-box; and some directly derived, in unimpaired traditions of form, from Babylonian, and Assyrian, and Greek originals: all the work of to-day, and as perfect in their art of to-day, as if they had come down to us from the days of our earliest knowledge of such ornamental objects: and he defied the most skilful of the manufacturers of America and Europe, to reproduce any of these objects in all the refinement and charm of form and decoration of the original designs The bead trinketry, for the adorning of the gods, had for years past been exhibited in Europe, and imitated at Vienna, and other pushing, hustling manufacturing centres of the West, but these counterfeits at once betrayed themselves by their clumsiness of construction, and crude and clamorous colouring. Finally he exhibited an Indian lady's slipper of coloured leather, the decoration of which was inwrought by scratching conventional floral scrolls through the coloured surface of the leather into its naturally light brown coloured substance, with the most exquisite delicacy of touch and fascination of effect. If, he said, there was any young lady in the room wearing the fellow to that sweet, dainty, Scythian slipper, at the close of the meeting the Fairy Prince would be at the door downstairs with his carriage and pair to drive her to her home.

Mr. Lewis F. Day, referring to the second of the two criticisms anticipated by Mr. Burns, thought that he did lay himself open to the suspicion of suggesting a course which would have the effect of doing away with something of the character of Indian art. He was surprised at the Chairman's interpretation of the paper as a plea for tradition. To him the anchor of it had seemed hardly to appreciate tradition in art at its true value. Mr. Burns scored a point when he suggested that to found yourself upon tradition was to let your ancestors do your thinking for you. But that was not quite a fair way of putting it. Tradition was the sum of all experience; all advancement in art started from it—more especially, one would think, in a country where caste prevailed. It was tradition which had brought Indian art to the perfection it had once reached. If Indian art was now as debased as Mr. Burns seemed to say, it might be necessary to hark back to Nature. But the starting point should still be tradition. Modern conditions had also, no doubt, as Mr. Burns said, to be taken into account, and it was inevitable that, under our Empire, something of European influence would infuse itself into the Eastern idea. That, however, was a very different thing from the Europeanising of Indian art.

He should be sorry to believe that there was no demand, no scope for Indian art. If, following our architecture, Renaissance design was to be imposed upon the native, Heaven help Indian art! He preferred to believe in native art; and he thought that, much as the Indian craftsman might be helped by sympathetic and intelligent European guidance, he should be allowed to follow his inherited instinct and go his natural way. If he was to do anything worth doing he would have to stick to his Oriental traditions.

The CHAIRMAN said he did not see anywhere in the paper that the author wished to do away with tradition, but rather the contrary.

Mr. E. B. HAVELL (late Principal of the Calcutta School of Art and Art Gallery) thought that in all the discussions referring to Schools of Art in the last twenty years people had shut their eyes to the vital point at issue, namely, what was the use of one section of a department, a very small, insignificant section, preaching and practising principles of art which the rest of the department and all the other departments of the State utterly disregarded? In Europe nobody expected Government to be artistic, but in India things were very different. The people of India were an artistic people, or they were until Englishmen began to educate them, and they believed that the Government was artistic. Sometimes even Government itself believed that it was, and that made matters much worse. The real question was whether the British people individually, collectively, and administratively, were an artistic example to the people of India who followed their own artistic traditions. For example, taking the question of dress, he could never walk in any part of India in which the influence of English education had not penetrated without feeling that the peculiar sartorial embellishment which custom had imposed upon him was a blot on the landscape and a disfigurement to the delightful lines and colour Indian tradition had given to Indian men and women. Little progress could be made in the national art education of Europe until artists as a body had sufficient courage to defy the caustic wit of the street arab and the authority of the artistic critic of the *Tailor and Cutter*, and adopt some distinctive professional costume, more beautiful in line and colour than the things produced by the tailor of to-day. Then again, could any artistic European climb the wonderful hills round Simla and Darjeeling, and look down upon the corrugated iron roofs and hideous constructions with which the beauties of Nature had been disfigured, without a sense of shame, when he compared them with the really beautiful and dignified domestic and ecclesiastical buildings which the Indian builders of the present day were still producing? The keynote of the paper seemed to be that although the artistic capacity of the people of India was still present, the ancient craftwork of India was as dead as the art of the Greeks or that of the Renaissance in Europe; but that he disputed *in toto*, and he thought that when the author had been longer in India he would alter his opinion. He (Mr. Havell) had with him some illustrations of living Indian art, architectural sculpture, done within the last twenty years by men still living, and he thought Europe might be searched from one end to the other without finding any modern work better, and very little was half so good. The wages of such men averaged fourpence a day, and they were unable to get artistic employment, except of the most insignificant kind, because when the Public Works Department in Calcutta required architectural decoration it sent either to Europe, or Bombay and obtained men who had been trained in the Bombay School of Art to copy ordinary European ornament. It was not that the Government could not afford the luxury of architectural decoration, because in the last twenty years it had spent lakhs of rupees on such decoration in Calcutta. It preferred to pay ten or twenty times as much for good, bad, and indifferent, mostly bad and indifferent, European art, as it would have to pay for first-rate Indian art. That was an utterly wrong policy. Lakhs of rupees had been spent in the last ten years in restoring ancient monuments and every rupee of that money might have been well spent, but that was archæology, not art. It was archæology again when European architects or engineers designed buildings in which they called an Indian style and set Indian builders to copy their drawings. The true function of Schools of Art in India was to endeavour to persuade the Education Department, the Public Works Department, and other departments, to put artistic principles into practice as thoroughly as India had always known how to do for herself. In the book of illustrations he had with him, the Printing Department of Calcutta had turned one plate upside down, and he thought that was very significant of the present state of art education in India.

Mr. A. CHATTERTON (Director of Industries, Madras) thought that in some respects Mr. Burns had underestimated the degree of difference between the state of art industries in the various parts of India. Speaking for Madras, the ancient art industries were not so much dead as dormant. For a very long time there had been but few opportunities for the best art workers to make a living by the exercise of their artistic skill, and it was for this reason and to meet the demands of so-called dealers in Indian art wares and hawkers of the same that so much bad and inferior work had been turned out in India during the last half century. Much of the ill favour with which the work of Schools of Art in India had been viewed had been largely due to the fact that it was very often not understood. It was only a few years ago that it was proposed entirely to abolish Schools of Art in India because they were thought to be doing unsatisfactory work, and that in face of the fact that many of the men who had been in charge of those Schools of Art had achieved, if

not world-wide, at any rate Indian reputations in regard to the work they had done. He thought the present position of Schools of Art in India was largely due to the fact that the work they had done had been to a great extent to meet the immediate necessities of the moment. As times changed in India the constitution of the schools was not sufficiently elastic to enable them to adapt themselves to the altered conditions without constant reference to the superior authorities controlling education. If Schools of Art in India had been left more to those in charge he thought they would have done a great deal better work. That policy to some extent had been recognised in Madras, and the present superintendent there had very little to complain of in matters of that kind as he had been allowed a much freer hand than his predecessor had, and already there was evidence that if a capable man was allowed to carry out his own ideas and to modify them from time to time to meet the changing necessities of the case the result would be much more satisfactory than when the schools were bound up in cast-iron rules and regulations. In Madras they had not a School of Art but a School of Arts, and he took it the term had much the same significance as it had in the title of their own Society the "Royal Society of Arts," and because it suggested a school to deal with a very much wider range of subjects than was generally to be found in the curriculum of a School of Art, he thought it was a more suitable designation. Mr. Burns had shown that if art was to be revived in the future something must be done whereby the people who passed through the schools might make a respectable livelihood. That part of the question had been too much neglected in the past, and he viewed with satisfaction Mr. Burns's general agreement with the policy in Madras of providing practical training for artisans outside the schools. He preferred, however, to see the workshops more intimately connected with the School of Art than Mr. Burns proposed. It seemed to him it would be better to have a larger staff and to delegate to some of the staff the work of managing the commercial side of the institution rather than to provide for it being carried on by an outside and independent Board. Many difficulties would be lessened if the training of the students in decorative work was completed on the commercial side of the school under the superintendence of the Principal. In Madras they viewed the decay of Indian art as being mainly due to the lack of opportunity afforded to the better-class artisans, and a remedy had been adopted recently which promised to meet with success. The Victoria Technical Institute had agreed to devote its resources to an attempt to improve the status of the Indian art craftsman. In Madras they had built a memorial-hall to commemorate the reign of the late Queen, and had filled it with a large collection of the art products of the Presidency. All these articles were for sale, and with the sale proceeds fresh commissions were given to the artisans so that they might be kept constantly doing the best work they could turn out. For the present it was proposed to devote a sum of about a lakh of rupees to financing, as it were, the Indian artisans, as it was thought that if they could be brought into touch with a more appreciative market they would return to their old methods of working and produce once more the artistic work for which their forefathers were famous. The sales had largely increased, and a gratifying feature was that the place was to a large extent patronised by the Indians themselves, who expressed surprise at the beautiful work produced.

Mr. ROBERT F. CHISHOLM, F.R.I.B.A., most emphatically endorsed everything the author has said not only with regard to the history of the Schools of Art in India, but also to the very admirable scheme he had laid down as to the future of those schools and the way they should be conducted. He (the speaker) had practically tested the scheme, because in the seventies he had been allowed to use the school of industrial arts in Madras as an art workshop, and in that way to make the work of artisans really useful. He had thought that in a short time he should be able to improve the style of drawing in the school, making the institution self-supporting, and execute the buildings entrusted to his charge without having to indent on the Secretary of State for European articles. In three years he realised his most sanguine expectations. The drawings by the students were quite equal to those produced at South Kensington in the lower stages. The institution, which was a dilapidated set of sheds, was remodelled into a presentable institution, and the industrial art work of the post and telegraph office in Madras was entirely executed by the students, every article being supplied through the school of arts without a single foreign importation being used except pot-metal glass and pig-iron. Then two difficulties arose. On the educational side it was impossible to carry the students further without taking them into figure drawing, and to do that would be to destroy any lingering of native art that might exist, because it would be impossible, after teaching a student anatomy and the drawing of the figures to set him down to draw six arms on a single body, or to study flesh tones in the green or pink incarnations of Vishnu. On the industrial side in the lapse of time between one public building being finished and another commenced the school had to become a kind of State manufactory dealing with public funds. There was no objection to that, but it was impossible to carry it out without the support and co-operation of the Government. He thought Mr. Burns's scheme was the only way of solving the great difficulty connected with the industrial arts of India. No one could respect the ancient arts of India more than he did, but the question of what was the ancient art of India was one upon which very few people would agree. He had been shown one of his own pots by a lady collector as a specimen of a beautiful lost ancient art! He disagreed with

the author as to the cause of the failure of Bombay pottery. That failure was really due to the fact that an unwise attempt was made to make the pottery useful. The Bombay pottery, which was, of course, Sind pottery, depended for its beauty on the peculiar colours of oxide of cobalt, copper, and manganese, fired at a very low temperature, and the three resulting colours, a beautiful green-blue, an exquisite deep blue, and a sepia, were combined in the pottery with the most beautiful effect. If, however, the pot was fired in a high temperature the whole thing was ruined. The Sind pottery was beautiful both in form and colour, and he thought there might be a very valuable future for it if no attempt was made to make it useful. It should be regarded an an ornament and treated only as a vehicle for artistic display. The decision of the Government with regard to public buildings being built in the Renaissance style was deplorable, and must lead to the most deplorable results. The only art in India was the native art, and it must not be allowed to degenerate into a bad echo of Western art.

Sir WILLIAM LEE-WARNER, K.C.S.I., who occupied the chair during the latter part of the proceedings, in proposing a vote of thanks to the author, said the paper showed the highest sympathy with what there was good and ready to hand in India, especially the wonderful memory of the India people and the marvellous fertility and richness of Nature from which they could copy. How far Schools of Art could turn those natural advantages to greater value was a moot question. He had spent the whole of his life in endeavouring to see that Schools of Art, either in Bombay or elsewhere, were not destroyed, as they had frequently been threatened by the constant changing of ruling authorities. He wished that the discussion had more emphatically shown the advantages of maintaining even the little flicker of light that existed, for he believed that benefits were derived from the Schools of Art. He had been pleased to notice throughout the paper no word of grumble from the author, who, with his predecessor, had done disheartening work with cheerful heart.

Sir GEORGE BIRDWOOD seconded the motion, which was carried unanimously.

Mr. BURNS briefly acknowledged the vote, and the meeting terminated.

Mr. BURNS, who was prevented by want of time from replying to the discussion on his paper, writes :—

I desire to thank Sir William Lee-Warner and Sir George Birdwood for the kind and flattering manner in which they referred to my paper, and to the work I have been privileged to do in Bombay. I value Sir George Birdwood's appreciative words the more, because they have been uttered after listening to theories and suggestions which, I am aware, traverse much of the teaching of his whole life. Despite apparent differences, the end we all have in view is the same, namely, the preservation of Indian art from being so influenced as to be entirely supplanted by that of Europe. It is when the road to that end is discussed, that divergences of opinion appear.

In the interesting discussion that has arisen from my remarks and suggestions, I notice that those gentlemen who disagree with me as to the right way to our common goal have done so upon one or more of three grounds, namely, the accuracy of the facts I have brought forward, the soundness of the theories I have propounded, or the practical character of the remedies I have proposed. With regard to the facts, I can only say that I have attempted to give a true and unbiassed account of the condition of the artistic industries, so far as my observation of them goes, in Western and Central India. In other parts of the country the outlook of the indigenous craftsman may be brighter. I trust it is so, but what cannot be denied is that every year European designs and articles are being imported into India in increasing numbers, and that apparently India unaided cannot or does not wish to stop this invasion. It is true that Mr. Havell has denied *in toto* that the ancient craft work of India is exhibiting symptoms of decay, though I cannot see how this denial can be reconciled with his admission that it is being ruined by European influence. With art as with life it has always been a battle for the survival of the more vigorous, and if Indian art still possesses its ancient vitality, it may well be asked how it comes to pass that the art of Europe is able to influence that of India at all. A similar struggle was seen in the Middle Ages in Europe when the tide of the Italian Renaissance swept away the Gothic art in England and France. In our own time, in a lesser degree, we have seen the great influence the art of Japan has had upon the art of Europe, but can it be contended that the art of India has exercised any similar or appreciable influence upon Western art at any period since the two came into contact? On the contrary, it requires even a less period than I have spent in the country to convince an unbiassed observer that from the day India ceased to be isolated the art of the West has increasingly influenced and modified that of India. If, as Mr. Havell holds, Indian art is full of vitality, it will fight its battle without any outside assistance; but if, as I, with other speakers contend, it requires careful guidance during this period of transition, then it seems to me that the apparently longer road of taking the designers and craftsmen back to the first principles of their art, and once more rebuilding, will in reality be both the shortest and surest way to infuse new vigour into Indian art which will make it proof against any alien influence. As I have said, the end we all have in view, and our aspirations, are the same, but our ways of attaining them differ. These aspirations and the theories we weave round them are fascinating in themselves, and are valuable for the purpose of focussing attention on

the subject. They may be indulged in freely when the theorist is six thousand miles away from India, and free from the responsibility of guiding the future careers of five hundred art students. It is when the question of training these five hundred students into citizens, each of whom shall be able to live by his work, and become a useful member of the community, has to be practically dealt with, that one's theories are so often found to fail to fit in with the conditions of the moment. I cannot agree with Mr. Havell that the keynote of my remarks is contained in the sentence "that although the artistic capacity of the Indian people is still present, the ancient craftwork of India is as dead as that of the Greeks, or that of the Renaissance in Europe." I should say that the keynote of my paper is that we have, in the past, attempted to carry out our theories of what Indian art might be regardless of the changed conditions of the country, instead of making those conditions the basis of our theories. If it were made an indictable offence to introduce into India any article of European design, I agree that the problem of preserving Indian art from European influence would be much simplified; but is there a theorist amongst us who would venture to propose so drastic a remedy? Unless we are prepared to do something very like this, we must accept the conditions as they are, and strive to our utmost to make the best artistic use of them. So far from being obsessed by the idea of teaching the craftsmen of India to manufacture his handicraft work in imitation of Europe and America, I can assure Sir George Birdwood that my mind is obsessed by the idea of training young India to develop her innate capacity in order to be independent of the West. With him and Mr. Havell, I regret the change in the conditions under which the craftsmen of India now have to work, and were it within my power would gladly assist them in banishing European art from India forthwith, but as the power to do that is absent, it appears to me that as a practical servant of the country the only thing to do is, as I have said, to make the best artistic use of the conditions as we find them, without wasting breath in railing at them, and to keep steadily before one's mind the fact that although it may not be within the power of any School of Art to produce, at call, a genius, it is possible to impart to all students sound principles in design, and to make them thorough and expert craftsmen, and so arm them for the battle of life and train them to become useful citizens. Thus equipped, I have complete faith in the power of the people of India again to take the high place they formerly held in the world of art, and to make that place a reflection of Indian ideals and character.

In continuation of the remarks which he made at the meeting Mr. CHATTERTON writes:—

It is a matter of regret there was not time to discuss adequately the very valuable practical paper which Mr. Burns read. It dealt with matters of live interest to the people of India and was an important contribution to the discussion which has been going on for a long time regarding the indigenous industries of India and what steps should be taken to enable the handiworkers to recover their local position or to tide over the period of transition in industrial matters through which India seems to be passing. This again is one phase of the great question which occupies the attention of everyone concerned in the administration of India at the present time—the development of the material resources of the country was to provide suitable employment for the ever-increasing number of those who have received a modern education, and what was perhaps even most important to mitigate the severity of the frequently recurring labour famines due to the dependence of too large a proportion of the population upon agricultural pursuits for a means of livelihood. The right course to pursue is to encourage industrial development in every possible way and by every legitimate means. New industries must be started, and the existing indigenous industries organised to meet the changed conditions of modern times. The resources of science must be placed at the disposal of the people of India and facilities provided for technical education and technical investigations. The more general diffusion of elementary education is essentially a preliminary step, and in this direction I am glad to say a great deal is now being done. The artisans of India are very ignorant, very superstitious, and intensely conservative, yet they are not altogether devoid of enterprise, and much could be done if they were supplied with capable leaders and definite lines were laid down as to the policy which should be adopted to bring about an improvement in their material condition. Of necessity this must be the work of Government, and in Madras a special department has recently been created to deal with industrial questions. Mr. Burns realised that something similar was required in Bombay, and the establishment of a technical laboratory in Bombay to inquire into and improve the processes employed by potters, weavers, calico printers, metal workers, and cabinet makers is apparently the initial effort in that direction. It is questionable, however, whether the School of Art is the proper institution in which to carry on such work, and I think that in Bombay, as was the case in Madras, it would rapidly grow beyond the means of control of the Education Department, and would become sufficiently important to need a new department to carry on the work and develop it. Something more than mere industrial schools for the training of boys is necessary. The younger artisans must be provided for and their training can only be satisfactorily effected in workshops where methods and processes are carried on under the conditions which must prevail in factories. I think Mr. Burns is very far from accurate in stating that "all attempts that have hitherto been made to mix up business with teaching in the Schools of Art in India have proved either educational or business

failures." I hope I am not claiming too much for Madras when I state that in this direction they are in advance of the rest of India and have already obtained results which promise well for the future and give them the assurance that they are working on the right lines. The difficulties no doubt are great, but they have been overcome, and under the superintendence of properly qualified men I think industrial development and industrial education can well be carried on conjointly. The slender resources of the State and the lack of organisation in native industries preclude the following of European methods, and it is better to work an admittedly imperfect system that is practicable than talk about a more perfect system for the carrying out of which adequate funds cannot be provided. It is obviously impossible on the present occasion to discuss this issue thoroughly, and I only allude to it to indicate that a great deal more has been done in other parts of India than Mr. Burns seems to be aware of. Dealing with the paper generally, I think that Mr. Burns has presented an accurate account of the state of Bombay art industries as applicable to all India. It certainly is not so especially in respect to Madras, where there have been other influences at work to counteract the baneful effect of Western civilisation on the artistic handicrafts of the Presidency. I would particularly like to draw attention to the work of restoring the temples of Southern India to even more than than their pristine splendour, which has been taken up and carried on for many years past by the Nattuscottar Chetties of Madras—a work on which they have spent enormous sums of money, and kept in continuous employment a large number of the most skilful hereditary art craftsmen of the Presidency. It was done in a very unostentatious way, and very few people knew anything about it, but a visit to some of these temples would convince anyone that the Indian artisan has not yet lost his cunning, and that, placed in a suitable environment, he is still capable of planning as great works and bestowing upon them the same careful attention to detail as his forefathers did, when the land was still under the sway of the Dravidian princes and polygars.

Colonel T. H. Hendley, C.I.E. (President of the Art Conference in Lahore) writes :—

I am glad that Sir George Birdwood and other speakers do not share Mr. Burns's depressing view that the Indian craftsman is living on a dead past; the power is still there, but, as Mr. Lewis Day has said, it is only dormant. For the moment it seems to me that it has been submerged by too violent contact with the West, by the rapid communications of the age, and by the injudicious and often ignorant patronage of a wealthy, but, from an art point of view, uneducated public. I have always hoped and believed that the chief purpose of Schools of Art in India was to stand between the indigenous craftsmen and all these disturbing influences, by encouraging and helping them. Such aid can be afforded in many ways; for instance, by greater care in selection of materials, with more attention to accuracy and finish in workmanship, and by very slight modifications, Indian productions might be made commercially more profitable, without injury to their importance as examples of Oriental art. I am pleased that Mr. Burns recognises the good work which was done in the past by my friends, Messrs. Kipling and Griffiths, and the more so, because the influence such men exerted is sometimes under-estimated. It has also been the fashion at times, as I think somewhat unjustly, to look upon official authorities as always unsympathetic. It is true, as Mr. Burns has told us, that proposals have been made to abolish Indian Schools of Art, or to convert them into technical schools; but on mature consideration they were preserved. In 1893, the Secretary of State even went so far as to state that "there was a general consent that they served no really useful purpose." This led not only to a careful enquiry into the matter by the experts who were present at the Second Decennial Art Conference, which was held at Lahore in January, 1894, but to an invitation to the local Governments in India to express their opinions. In the report of the Conference it was urged that the schools had been most useful in many ways which time will not allow me to mention in detail now. It was held, moreover, that they had had a most beneficial effect in protecting the arts and artisans of the country from the extraneous and dangerous influences to which the conditions of modern life and the facilities of interchange of ideas had subjected them. The members of the Conference thought that the true principles of art, and especially of Oriental art, which had been taught in the schools, had been most valuable in retarding the decay of Indian art. I need not, however, quote further from the report, because, in the main, the views of the Conference were approved by the Government of India, and were finally accepted by the Secretary of State, and thus the schools were preserved and have continued to do good work. Further, as Mr. Burns has proved to us, by the account of his own experience and judicious management, they are still bringing the knowledge and practical methods of the West to the aid of the hereditary skill and aptitude of the East; but I am particularly pleased to hear that he looks for ultimate success, as we members of the Conference did, to the inculcation of the true principles of art, and especially of Oriental art, rather than to teaching a slavish imitation of the past and adherence to its traditions. In the Secretary of State's despatch to which I have referred, it was observed that "great and ever-increasing difficulty is found in securing the services of European teachers fit to be entrusted with the direction of such schools (of art) in India." So far we have evidence to-day that such men can still be found, but if they are to be trained in institutions arranged on the basis of materials, as is now threatened, it will be doubtful if they will be

forthcoming in the future. I regret that Mr. Burns finds that there is still such a strong tendency to use European decoration in Indian buildings. There seems to me to be no general need for this, although we must not be altogether out of sympathy with the inclination of many wealthy Indians to prefer Western designs and fashions, especially when they happen to be more suitable as they think or more comfortable and convenient than their own. A word may be said even for the objectionable corrugated iron. The late Maharaja of Jeypore, when someone remonstrated with him for allowing verandahs of this unsightly material to be attached to the walls of his marble palaces, said that, at least, they were more useful and economical than the striped curtains which they replaced, which indeed only looked well when they were new. Moreover, the Bengali, who roofs his shops and huts in his villages with such iron, has some right on his side when he urges that it is less liable to burn than the picturesque thatch which it replaces. Such are some of the difficulties with which the schools have to contend, but difficulties can be overcome. Thus I might airly notice how the Indian craftsman can still hold his own and be employed with success. I think, I am right in stating that his services have been used almost without exception in decorating the numerous buildings which have been designed by Sir S. Jacob, and I believe by other architects, in Rajputana. In the Jeypore Museum, for example, the beautiful carved work in marble is all purely Indian. Much of it was no doubt reproduced from old Indian designs, but a good deal is new, though it was designed in the spirit of the past. I am reminded particularly of how each individual craftsman was allowed to model in clay a capital and a base of a column for one of the arcades of the museum, which, if approved, he was permitted to execute in stone and to carve his name upon his work. This was not slavish imitation but real living and progressive art, and I firmly believe that if encouraged there will be found in most parts of India craftsmen who are capable of doing similar work; but it is mainly to the Schools of Art with such superintendents as Mr. Burns, and to such sympathetic architects as Sir S. Jacob, that we must look for the wise guidance and assistance to which I refer.

THE LORD CHIEF JUSTICE ON THE PATENTS ACT.

The Lord Chief Justice, in opening the proceedings of the "Law, Political Economy, and Legislation Affecting Chemical Industry" Section of the International Congress of Applied Chemistry, at South Kensington, said that in choosing his remarks he naturally gravitated towards the subject of which he had most experience—the right method of legislating upon and dealing with scientific knowledge. He wished to approach the subject from the broadest possible standpoint, and to consider the principl upon which legislation should proceed, not in thi country alone, but in all civilised countries. He di not believe there ought to be different rules i different countries, but as far as possible they ougl to see whether in the British Empire, France, Ger many, the United States, and other great countrie they could not approximate to an international cod in connection with the proper protection of inven tions. It was from that point of view he wished t consider a step which had recently been taken i Great Britain, a step which, to a certain exten followed the example of some other nations wit regard to the making it a condition that a pate should be worked in the country in which it had bee taken out. In his opinion that was a step in th wrong direction which would discourage inventor and which would make people revert to secr processes, one of the worst forms by whic inventions could be developed. Further, it w hard upon the genuine inventor, who was oft a very bad man of business indeed. He h always maintained that view. He would take kindred illustration—the enactment adopted in En land, against his express wish, destroying provision specifications. Let them protect the investor much as they liked, but let them not do anything destroy public knowledge. Take the case of t scientific men, many of whom had the power of inve tion and were always thinking of something ne but who often were wholly unfitted to work out t inventions themselves. The real advantage to t public in those circumstances lay in other peop taking up the invention and working it. At prese the working of a patent was compulsory, and application might be made to revoke the patent ev in the country in which the patentee resided, a that appeared to be driving an idea to an exce He knew there was a strong impression—he was n the least in favour of it from the Protectionist poi of view—that by this means they would then devel the industry of the particular country. It seemed him that if they were to lay down this test abo working they would meet with many difficulties, f the conditions were different in dealing with chemic products and with general manufactures, and wi subordinate parts in an old machine and an entire new machine. They were approaching the subject fr the wrong standpoint. He wanted in the first pla to protect the inventor so that the product of h invention would be used with advantage to hims and with the largest advantage to the public. they desired to interfere with the monopoly rights a patentee, the proper view to take was that the should be freedom of working on a fair licence, if t patentee did not sufficiently work the patent himsel Under those conditions the difficulties about injun tions would to a large extent disappear. If a patente were a dog-in-the-manger, and would not allow patent to be worked except on prohibitive terms, l all means have an independent tribunal which shoul

ay on what conditions and on what terms the patent ought to be worked. But if they allowed people who really wished to work that patent to do so on fair terms under licence, they need not put on the patentee the burden of working it when he did not wish to do so. There were numbers of illustrations which showed that compulsory working would not be a real remedy for the evil, and would at the same time impose upon many patentees a very great burden. The inventor should be given a fair and not an excessive reward for his invention, and should be freed from those commercial difficulties which had embarassed so many men. If there were a capitalist, a merchant, or a manufacturer who felt he could make good public use of a patent, let him work it on terms fair to the patentee, but do not let them say that a patent was to be revoked because the patentee was not able to work it. He hoped it was not too late to suggest from an international point of view that patents should be worked by those desirous of working them on fair royalties, paid to the patentee. There ought to be international recognition of invention and discovery. There was no class of invention to which the observations he had made applied more strongly than that of chemical industry. It seemed to him that knowledge was the birthright of no particular nation, but ought to be shared by the whole human race. There ought to be no temptation to bottle up or keep secret the discoveries of scientific men or the results of their labours. The perfect system would be to give every inventor a fair and full—might he say a generous ?—reward for his invention, and relieve him in many cases of the anxiety of developing it, so that he might be free to pursue his studies for the benefit of mankind, and to investigate the inexhaustible fields of knowledge yet unexplored.

COMMERCIAL DEVELOPMENTS AT NAPLES.

The recent visit of the King and Queen to Naples lends interest to the last commercial report emanating from the British Consul-General at that port, which has just been issued from the Foreign Office. Unfortunately, 1908 was a gloomy twelvemonth, owing to a drought such as had not been known in South Italy within the memory of man, while the terrible disaster of the Messina earthquake occurred just three days before the close of the year. The crops which failed largely were the corn crop, including maize, the green crops, including hemp, flax, lucerne, and beans, and the oil crop. The only abundant yield was that of the vine, and this followed on the productive season of 1907, so that it is hardly surprising, in the congested state of the market, to hear that people have been talking about replacing the cultivation of the vine by cotton or tobacco. It is satisfactory to find the United Kingdom at the head of the list of the chief importing countries, though, in respect of exports from Italy to foreign countries, we actually stand at the bottom of the list. England's chief import is coal, most of which goes to Genoa. In order to encourage trade generally between Italy and the United Kingdom, an agreement has been arrived at to admit free from every duty patterns and models with which it may be intended to procure orders, and which are *bonâ fide* not for sale. British commercial travellers in Italy and Italian commercial travellers in the United Kingdom may accordingly enjoy this privilege, subject only to certain easy formalities, intended to guarantee the re-exportation of the articles when done with, or their introduction into bond. From a British-Indian point of view, it is interesting to see that during the year a company has commenced the manufacture of jute textiles, the raw material being imported from Calcutta. The accommodation at the port of Naples, for landing both passengers and goods, is lamentably deficient, the state of things as regards the latter being a grievance specially affecting British trade, owing to the quantity of grain carried in British bottoms. Another matter touching our shipping interests, is that the Italian lines of steamship companies are taking away, year by year, more of the emigration traffic from the foreign lines. They have already more than half of the whole traffic, while there is a Bill before the Italian Parliament which, if passed, will make it still more difficult for foreign lines to continue carrying emigrants.

Probably, however, the most interesting matter mentioned in the report relates to a pending undertaking in the neighbourhood of Baia and Pozzuoli, two localities recently visited by King Edward and Queen Alexandra. Here, we are informed, it is proposed to revive a project partially carried out by King Bomba some sixty years ago. The new work is to consist of a navigable canal about three-quarters of a mile in length, to be dug from the excellent anchorage of the Gulf of Baia to the lake of Avernus, the well-known classical basin, which occupies the site of an ancient crater and was popularly supposed by the Romans to be the entrance to the infernal regions. It is very deep and the proposal is to construct there docks and shipbuilding yards. A quay was actually built round the lake by the King of Naples some sixty years ago, and a small canal was also excavated as far as the sea, but the cost of completing the undertaking proved to be too great, and further operations were abandoned. For the present project capital has, it is said, been supplied from Belgium. But the most notable circumstance, not mentioned in the Consular report, is that the whole scheme would appear to be a restoration of an important work which was planned and carried out by Agrippa, Octavianus' great scientific general, in the century just before the Christian era. Even in those days the depth and proximity to the sea of Lake Avernus* seems to have attracted the

* The depth and steep sides of the former craters are mentioned by Vergil in the well known lines:—

Facilis descensus Averno,
Sed revocare gradum, superasque evadere ad auras,
Hoc opus, hic labor est!

notice of engineers, and when the coasts of Italy were being ravaged by the fleets of the younger Pompey, Agrippa, a born engineer and geographer, conceived the plan of organising a navy capable of coping with that of his foe. He united the Lucrine lake with the sea, and joined the former with Avernus. In this sheltered port named Portus Julius, the fleet was built and equipped, and 20,000 manumitted slaves were trained in rowing and naval manœuvres till able to cope with the seamen of Pompeius, who were defeated successively at Mylæ and Naulochus. The subsequent great victory of Agrippa over the fleets of Antony and Cleopatra at Actium, an event which made Augustus emperor of the world, may be said to be a further fruit of his naval policy, as evolved by this remarkable work. How the harbour fell into disuse is not precisely known, but there may have been even in classical times a gradual upheaval of the Lucrine Lake, which made access from the sea an impossibility. In 1631 there was a great eruption of Vesuvius, which had been quiescent for 492 years, and a hill, several hundred feet in height and about three miles in circumference, suddenly arose in a single night from the bottom of the Lucrine Lake. It was appropriately called Monte Nuovo, which name it still bears. The circumstances are picturesquely narrated by Sir William Hamilton, the well-known British ambassador at Naples in 1776, and friend of Nelson, who devoted several years to the most careful investigation of volcanic phenomena.

THE PRODUCTION OF BRIQUETTES.

Only fifty years ago the dust of coal was considered to be entirely useless, but since then a great change has taken place, and at present in Rhenish Westphalia the Ruhr coal district alone produces 3,000,000 tons of briquettes each year, according to the United States Consul at Barmen, who in a recent report has furnished some interesting details regarding the advantages of the use of sulphite pitch, with a preliminary statement concerning the making of coal briquettes with tar pitch in general. Up to the present time coal tar pitch has been used for making coal briquettes, and its production in the past ten years has increased about 100 per cent. Most of the coal tar pitch is produced in England and Germany, the latter country only being able to produce for its own consumption, while England supplies the remaining customers, *i.e.*, America, Russia, and Belgium. The coal tar pitch is an excellent binding agent for baking and coking coal, especially bituminous. It burns easily, and gives the briquettes hardness for long distance transport, but various qualities of good material cannot be turned into briquettes with it, thus making its common availability impossible. Its numerous disadvantages are as follows :—It produces very much smoke, and has a very disagreeable odour ; it cannot stand a high temperature, and becomes soft and difficult to use in hot weather : the dust and fumes of coal tar being corrosive, are very injurious to the skin, eyes, and lungs of the workmen employed, causing diseases of those organs. The low temperature at which it ignites, although an advantage when used with soft bituminous coal, becomes a great disadvantage when the attempt is made to use materials that burn less easily. The coal tar becomes soft and burns much more rapidly than the coal flowing out of the briquette, leaving the coal to fall to pieces in dust and remaining unconsumed. For this reason it has been impossible to use in the making of briquettes, anthracite, semi-anthracite, or coke gravel with coal tar pitch, it being unable to resist the heat and pressure of the blast furnace; therefore a binding agent which overcomes all of the difficulties mentioned, and is capable of making use of these materials in the production of briquettes, which up to the present time have been lost, ought to have good results for the future. This long-sought-for binding agent is said to have been found in the "sulphite pitch." The material is obtained in the process of manufacturing sulphite cellulose. The wood is put through a washing process in lye, by which the fibre is cleared of all resinous ingredients, it being pressed out from the wood pulp. Thus far, according to the American Consul, the material has been entirely useless, but, through a cooking process, it is reduced to a highly glutinous substance called "sulphite pitch." The sulphite pitch possesses many qualities which show its excellent advantages as a binding agent. It is intensely glutinous and possesses a high binding power. In the ordinary briquettes of bituminous coal, from 7 to 10 per cent. of coal tar is used, to give it the proper hardness, and with the use of sulphite pitch the same results can be obtained by the use of 5 per cent. There are qualities of coal and ore that can easily be used in making briquettes with from 2 to 3 per cent. of the sulphite pitch. Sulphite pitch burns without smoke or smell, and is said to be an ideal fuel for the household as well as for industrial purposes. In cities where the smoke nuisance has hitherto prevailed, the use of briquette pitch may form a solution of the smoke question. Trials have already been made with coke briquettes made with this new process, in blast furnaces, and on torpedo boats. The former tests, according to the Consul, not only showed a saving of 30 per cent. coal, but the iron was almost entirely free from sulphur. In its trial on the torpedo boat it not only proved a perfect fuel, but the entire absence of smoke proved its advantage over other fuels in time of war.' Sulphite pitch does not soften under heat, and burns at a high temperature. It can be ground to any consistency, ... produced directly in any form of powder ; ... can be obtained in any country where there are cellulose mills, and it is very cheap, unlike the coal tar pitch, which is not so cheap. In general sulphite pitch consists of the following substances: Coke, 25 to 35 per cent. ; volatile matter, 50 to

per cent.; ashes, 8 to 12 per cent.; and water, 10 to 15 per cent. The latest chemical tests have proved that the percentage of ashes can be materially reduced. Through the origin of sulphite pitch, its ashes contain sulphur up to 20 per cent., or 2·5 per cent. of the sulphite pitch. One of the latest uses to which the sulphite briquette has been put, and in which it has proved successful, is as a dust layer for roads. Sulphite pitch was dissolved with water to a certain consistency and sprayed over the roads, and such a dressing was sufficient to prevent dust arising for at least six weeks. The production of sulphite pitch, as well as its use in the process of briquette making, call for special processes and machinery, which have taken years of costly experiment to develop successfully, and both the material and its use for briquette making are patented in all the principal countries. It is not supposed that sulphite pitch will in any way interfere with the coal tar pitch, in its use for the making of briquettes of soft bituminous coals, but the superiority of sulphite as a binding agent, rendering possible briquette making with the harder coals and cokes, and also with iron dust and other ores, opens up a new and very important industry. Already a large coke briquette factory has been built in Germany, at Luttringhaus, near Barmen, Elberfeld, and the entire output of the factory was sold out at once. Another large factory is in course of construction at Aix-la-Chapelle.

HOME INDUSTRIES.

Cotton Spinning Industry Accidents.—The annual report for 1908 of the Chief Inspector of Factories and Workshops refers to the frequent accidents from carding engines. Many are due to the hinged cover of the carding cylinder being left open for the process of "stripping" the cotton waste from the cards. In a short time further "strips" accumulate in front of the revolving cylinder and conceal it, and an operator who attempts to remove them under the impression that the cylinder has ceased to revolve, may have his hand crushed between it and the cover. Nor is the danger ended even when the belt is disconnected from the driving pulley, since the cylinder will often continue to revolve for a minute or two. The inspectors have accordingly pressed for the adoption of some locking device which will prevent the cover from being opened until the cylinder has come to rest, and will render it impossible to re-start the card until the cover has been closed. Another source of accident in the cotton spinning industry has been the practice of transferring the belt from the fast to the loose pulley (and *vice versâ*) by hand, and the inspectors have advised the provision and use of strap forks for the purpose. But this suggestion is opposed by operatives as well as employers; and, in order to expedite the general adoption of the necessary safeguards for carding cylinders, it was agreed, after prolonged negotiations with the Federation of Master Cotton Spinners' Associations, to allow the question of strap forks to remain open for the present, on condition that locking arrangements for the cards, conforming to the conditions mentioned above, are provided without delay.

Insurable Interest.—An important section of the Insurance Companies Bill now before Parliament relates to insurable interest, a question that has caused disquiet of late. The Bill lays it down that persons may have an insurable interest in the lives of their parents up to a reasonable amount, on account of funeral expenses, and the Bill is retrospective in so far that it provides that no policy already taken out shall be deemed void by reason only of the fact that the person effecting the policy had not at the time an insurable interest in the life of the person insured. It is very desirable that there should be legal sanction on what has been done for long as an economic necessity by a large portion of the community. If the Bill becomes law without substantial alteration, as it probably will, its effect is likely to be to strengthen the position of every sound society, and to discourage the formation of undesirable concerns. One of the most important provisions is that relating to deposits required by the Government. Not only are all companies transacting life assurance business to deposit £20,000, in respect of fire and accident insurance, and bond investment business, but companies beginning to transact any of these after the passing of the Act are required to deposit a similar amount, and the deposit is also required from all companies which have started employers' liability business since August 28th, 1907. It is to be regretted that the Government do not, apparently, see their way to make the clause retrospective in respect of all companies. At least they might be put on the footing of employers' liability companies, and be made retrospective as from August, 1907.

The Scottish Mineral Oil Companies.—Last year there was a fall in the prices of nearly all the products of the Scottish mineral oil companies, but notwithstanding, they were able to earn profits amounting in the aggregate to £380,200, as compared with £372,340 in 1907-8. All the companies have maintained the distribution on their ordinary shares, the Pumpherston Company paying 50 per cent., the Broxburn 17½ per cent., the Oakbank and Tarbrax 15 per cent. each, and Young's 7 per cent. This has been made possible by the fall in wages, and the cost of coal and the other commodities which the companies use in their process of manufacture. The shale miner's wages rise and fall with wages in the coal trade, so that a reduction in the price of fuel coincides with a fall in wages. The outlook for the current financial year is not quite so favourable, the companies having now to face keener competition in various directions. The Standard Oil Company has recently reduced the price of paraffin wax by ½d. per lb., and the Scottish producers have had to reduce

the prices of both wax and candles to a corresponding extent. Lubricating oils and naphtha are also likely to bring somewhat lower prices, owing to decreased demand, and keener competition has to be reckoned with in burning oil which, however, provides now only from 10 to 15 per cent. of the income of the companies. The price of sulphate of ammonia, now one of the most important products of the companies, is likely to be maintained owing to the increasing Continental demand for it as a fertiliser.

The Milk Bill and Dairy Farmers.—It is not surprising that at the annual conference of the British Dairy Farmers' Association held last week strong objection was taken to some of the provisions of the Milk and Dairies' Bill now before Parliament. Everyone must sympathise with the main object of the Bill which is to insure that the public get pure milk, but exception is taken to the power given to a medical officer of health to stop the whole of the milk of a farm if a sample of that milk contain a single microbe of the bacillus tuberculosis. Microbes are particularly difficult to identify in milk as a matter of ordinary microscopical examination. Yet on this slender evidence a dairy farmer might be caused great loss by the stoppage of the whole milk of his farm. It is not every medical officer who is capable of properly inspecting a herd, a truth apparently recognised by the framers of the Bill, which provides that when he inspects he must have a veterinary surgeon with him. The better way would seem to be to select a properly qualified veterinary inspector. It may be assumed that the clause relating to inspection to which such strong exception is taken by the dairy farmers will be amended.

Wheat Supplies.—There is little likelihood of wheat values falling away appreciably in the immediate future. The signs rather point to advance. The Continental demand is growing, and German requirements more especially are likely to be considerable. The German normal requirements of wheat are now about 27,000,000 quarters per annum, and the last crop was officially estimated at 17,270,000 quarters. The requirements from abroad would accordingly be nearly 10,000,000 quarters; but, assuming that the high price of wheat will check consumption, it is most probable that Germany will require 8,000,000 quarters of wheat from abroad. English requirements from abroad are also very considerable. On the other hand, the world's visible supply is unusually small. The American-Canadian is the smallest on record at this date. In the last two months the exports of wheat from America have been very trifling. Nor is it likely that the "invisible" supply is large, for if there was any considerable quantity of wheat in the United States available for export the present high prices would bring it forward. India is to some extent coming to the rescue by shipping wheat to Europe at the rate of about 200,000 quarters per week, and will probably continue to do so for some months to come, otherwise the price of wheat would be a good deal higher than it is.

Railways and Traders.—In the course of his remarks to a deputation of traders who waited upon him in December, 1906, Mr. Lloyd George, then President of the Board of Trade, stated that in Germany there was "no such thing as railway risk," and he went on to say that "German traders are very satisfied with the railway system, and consider that the railway system in that country is doing its very best to assist and to promote industries, and even to develop the weak industries." An appendix to the report of the Board of Trade Railway Conference, entitled "Report on Railways in Germany," does not support Mr. Lloyd George's opinion—at least, his opinion when President of the Board of Trade—that German railway conditions are much more favourable to the trader than British. Take, for example, the alleged absence of owners' risk. The report referred to above—prepared by Mr. Nicholas C. Reyntiens, barrister-at-law, and Mr. C. H. Pearson, of the Great Central Railway Company — shows that the practice of the German railways is to insist on such regulations in regard to packing as will "serve a most useful purpose in furtherance of the elimination of possible claims," while if the railway administration are not satisfied that the packing is sufficient to relieve them of any actual risk they refuse to convey the goods unless the consigner signs a paper expressly declaring that the goods are "unpacked," or "insufficiently packed," thus taking the risk on himself. Nor does the Report confirm the German statements made to Mr. Lloyd George as to German traders being "very satisfied" with railway management. The inadequate supply of wagons, especially at the season of the year when water transport fails, is the cause of constant complaint directed by the public against the railway administration. The Report also contains much information as to general railway conditions in Germany, from which it would seem that the administrative control is a much more complicated business than servants of State railways here are inclined to assume. The alleged simplicity of the system of railway rates in Germany is not made out, since "the catalogue of rate-books in existence shows that there are approximating to 1,000 different published books of rates." Railway rates in Germany are purely station to station rates, to which must be added the cartage charges of the "spediteurs," who also play an important *rôle* as forwarding agents. "The many complications of the tariffs," says the report, "require expert knowledge, which can only be obtained by constant practice." As to competition, from a public point of view, in so far as it may be said to be a benefit to trade, it is practically non-existent in Germany. As between the State and private lines, competition is "effectually stifled by the various methods of control."

QUESTIONS AND ANSWERS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

STAINED GLASS WINDOWS.—I am obliged to N. H. for his reply to my question. But the point that puzzles me is, why for centuries we get only a brownish purple in stained glass, such as manganese (naturally containing more or less iron) would give, and then suddenly a rich violet purple. Is it implied that the substitution of soda for potash as a basic material would account for the colour? If, as N. H. says, "the peculiar properties of the cobalt ores of Saxony were only recognised about the end of the fifteenth century"—the mixture of cobalt with manganese would explain it all. But one had always taken it for granted that the sapphire blue of early glass was due to cobalt. If it was not cobalt, what was it, or what could it have been?—L. F. D.

ANSWERS.

EMBANKMENTS OF THE RIVER THAMES (see p. 343).—The question asked by "Londiniensis" is not easy to answer on account of the difference of opinion expressed by writers on the subject. As East London could not well have come into existence without these embankments, the general opinion is that they were formed either before the Roman occupation or immediately after that event. There are, however, others who do not date them before the Middle Ages. Probably the walls were formed at the earlier date, but were rebuilt at different times. The earliest recorded breach in the Essex wall took place in 1376, when great damage was done. The lands belonging to the Abbey of Barking were inundated and the resources of the Abbey were greatly crippled for many years by reason of the necessary outlay for the repair of the breach. There is now an inlet of the Thames above 1½ miles in length, with an area of nearly 60 acres, originally known as Dagenham Breach, and now as Dagenham Lake. This came into existence owing to a storm on December 17th, 1707, when a breach was made 400 feet long, and above 1,000 acres of land were inundated. Captain Perry succeeded in restoring the embankment, and drained the land, except the portion known as Dagenham Lake. This water is full of fish, and has the distinction of being the place where the old Ministerial fish dinners were instituted. There was a breach in the Kent wall in 1527 at Abbey Wood, and we hear again of "drowned lands" in 1563.

The late Sir George Airy, Astronomer-Royal, in a valuable article in the *Athenæum* (Jan. 28, 1870) on the Claudian Invasion of Britain, says that the walls were not constructed at that period. There are several references to the wall in early volumes of the Transactions of the Institution of Civil Engineers, but writers on London have been very neglectful in omitting all mention of these important works. The late Sir Walter Besant, however, is an exception, and in his work on *East London* (1901) he has an interesting chapter on "The Wall." He does not give so much information as might be wished, but he describes clearly what he observed in a walk on the wall from Barking, which he says is "the most curious walk that one may find within the four seas that encompass our island." "The wall," he adds, "is about fifteen feet high; at the base it is perhaps thirty feet wide; the sides slope towards the path at the top, which is about seven feet across; the outside is faced with stone, the inside turfed. . . . . On the land side lie the fields which have been rescued from this tidal flow; they are obviously below the level of the river; one understands, looking across them, how the river ran of old over these flats, making vast lagoons at high tide. It is useful to see the fact recorded in a book or on a map; but here one sees that it really must have been so." A full account of all that is known of these embankments would be of great value and abiding interest, but I do not know of the existence of any book devoted specially to this subject.—H. B. WHEATLEY.

FIRE WALKING (see p. 466).—Referring to "Maori's" question, in the *Journal* of April 23rd, I have with my own eyes seen a whole family walking on red hot ashes (coals) without any injury in the least being sustained. The family consists of men, women, and children, who walk once in every year, before a big audience, on fire. The ceremony takes place in about the month of January. Besides this, a month ago, a Mohammedan sayad had walked on fire, before a very big audience of gentlemen and leading citizens, and also in the presence of H.H. the Maharaja Saheb Gaekwar of Baroda. If "Maori" desires to see this personally, he may come over here when the time arrives, so that he will be able to see the scene with his own eyes. I may mention that the said sayad is not of this city but is a tourist.—RANEHHODDAL VORA, Baroda, India.

CATTLE FOOD FROM WOOD CELLULOSE (see p. 624).—A company was recently formed to work a foreign patent for extracting alcohol from sawdust. After the sawdust has been treated for this purpose it is mixed with molasses, and sold for cattle food.—W.

GENERAL NOTES.

FERRO-CONCRETE BRIDGE IN BURMA.—In a paper read recently before the Society of Engineers, Mr. W. E. Haldwell described the methods adopted in constructing a reinforced concrete arch bridge over a bridle road in a mountainous tract of country in Upper Burma. This, the Sinlumkaba Mill Bridge, is the first reinforced concrete bridge to be erected in that country. The bridge was constructed by the Burma Public Works Department, and is in one span of 40 ft., with a rise of 12 ft. in the arch, the entire width of the bridge being 9 ft., and the width of roadway inside parapets 6 ft. The level of the crown of the arch is 8 ft. above the highest known flood level. The entire arching was made of cement concrete, with two layers of reinforcing bars, the bottom layer being placed 1½ in. above the intrados, and the top layer 1½ in. below the extrados of the arch. The longitudinal reinforcing bars were placed 9 in. apart, with cross bars at right angles to them, at intervals of 2 ft., both longitudinal and cross bars (which were all ½ in. thick), being wired together at their intersections with $\frac{1}{16}$ in. wire. The thickness of the arch at the crown was 10 in., and at the haunches 3 ft. 9 in. Thus the distance between the two layers of reinforcement was 7 in. at the crown and 3 ft. 6 in. at the haunches. The backing of the bridge was formed by parallel spandrel walls, made of coursed rubble masonry in lime mortar, 4 ft. wide at the bottom and 2 ft. in width at the crown level of the arch. At this level a masonry wall 1 ft. 6 in. in thickness was built along either side of the arch for a height of 1 ft., thus acting as a retaining wall for the filling in over the crown, and on this wall the masonry parapet pillars of the bridge were built and connected by ⅞ in. square iron bars, which formed the railing.

OLD-AGE PENSIONS IN NEW ZEALAND.—Mr. Pember Reeves, late Agent-General for New Zealand, has given some interesting facts in relation to the working of the Old-Age Pensions Law in New Zealand. That law has now been in operation for a little more than a decade. Based more or less upon the Danish law, it has itself served as a model for the pension laws of the Australian Commonwealth, and to a large extent for the British Act of last year. It exacts no contributions, but grants free pensions to such of the aged poor of New Zealand as are not flagrantly undeserving. The maximum pension granted is ten shillings a week, and the age limit 65. To attain the pension the applicant has to comply with a number of stipulations, chiefly relating to nationality, good character, income, and property. As compared with the English law, that of New Zealand appears almost lavish in its offers. Instead of a maximum pension of 5s. after the age of 70, it holds out a possible pension of 10s. weekly after the age of 65. The Maori is eligible but not the Asiatic. Women are eligible whether married or single. Comparative poverty and a measure of respectability are the main qualifications. The average private income of the pensioners outside of their pensions is £8, and numbering 13,000 they possess between them private property amounting to something like half a million sterling. A pensioner may earn or receive as much as £34 yearly without being disqualified for a full pension. As the full pension is £26 a year this means that the State is ready to make a man's income up to £60. Above that deductions begin. A man with a private income of £59 a year is entitled to £1 pension only. A married couple when both are entitled to the full pension may therefore draw £1 a week between them. Five years' imprisonment for any disgraceful offence disqualifies the convict for twenty-five years, four convictions for minor but discreditable offences also disqualify though for a shorter term. Wife desertion and habitual drunkenness disqualify, but positive proof of an industrious life is not required. On the other hand, an applicant, if he would succeed, must be supported by the testimony of some person of good standing who has known him for a long time, and the authorities must be satisfied that for at least five years before making his claim he has led a sober and respectable life. The number of pensioners in New Zealand at 65 years of age, and qualified for pension, is about 40,000, the number of actual pensions about 13,000. The effect of the tests as to income, property, and character is thus apparent, the number of pensioners being but 32 per cent. of the whole of the aged class. Mr. Reeves estimates that the cost of the Act this year will probably reach £350,000, a considerable sum for so small a population, but scarcely a voice is raised against it. The expenses of administration amount to no more than 1·69 per cent. of the total cost since inception, and are entirely the affair of the Central Government.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 21...Victoria Institute (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi W.C.), 4 p.m. Presidential Address by the Earl of Halsbury.

FRIDAY, JUNE 25...Physical, Imperial College of Science South Kensington, S.W., 5 p.m. 1. Professor Carhart, "A Transition Point in Zinc Amalgam." 2. Dr. T. M. Lowry, "A Method of Producing an Intense Cadmium Spectrum, with a proposal for the use of Mercury and Cadmium as Standards in Refractometry." 3. Mr. A. Campbell, "The Measurement of Wave-length for high frequenc[illegible] Electrical Oscillations." 4. Dr. A. Russell and Mr. J. N. Alty, "An Electro-magnetic method of Studying the Theory of and Solving Algebraica[illegible] Equations of any Degree." 5. Mr. S. D. Chalmers "The Sine Condition in relation to the Coma of Optical Systems." 6. Dr. C. V. Drysdale, "Exhibition of a new Fery Thermo-electric Calori[illegible]meter." 7. Mr. F. W. Jordan, "An Instrument for Measuring the Strength of an Intense Horizontal Magnetic Field." 8. Professor Poynting and Mr. G. W. Todd, "A Method of Determining the Sensibility of a Balance." 9. Mr. G. W. Todd "The Balance as a Sensitive Barometer."

Journal of the Royal Society of Arts.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-fifth Annual General Meeting for the purpose of receiving the Council's Report and Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held in accordance with the By-laws on Wednesday, 30th June, at 4 p.m.

(By Order of the Council),

Henry Trueman Wood,
Secretary.

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the galleries of the Natural History Museum, South Kensington, on Tuesday evening, June 29th, from 9 p.m. to 12.

The Reception, by Sir William H. White, K.C B., F.R.S., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Engineers, in the Central Hall, commencing at 9 o'clock.

An Instrumental Concert by the "Red Band," under the direction of Mr. Thomas Batty, will be given in the Fish Gallery from 9.15 till 10.15 p.m., and from 10.30 till 11.30 p.m.

A Gramophone and Auxetophone Concert, under the direction of the Gramophone Company, will be given in the Shell Gallery at intervals from 9.15 p.m.

The following portions of the Museum will be open :—

The Central Hall, containing cases of specimens illustrating Mimicry; adaptation of colour to surrounding conditions; protective resemblance, &c.; also specimens illustrating the food of Fishes, and the life-history of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of

British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque deep-sea fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), the Lemon-sole (case 30), &c.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors n the First Floor of the Museum.

Visitors travelling by District Railway (or other underground railways in connection therewith) will be allowed free use of the Company's Subway, which leads from the South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These tickets have now been issued. Any member who has not received his tickets is requested to communicate with the Secretary. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by members, at the price of 5s. each, if purchased before the day of the Conversazione. On that date the price will be 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the Musical and other arrangements will be given in the Programmes which will be distributed on the evening of the Conversazione.

LAC.*

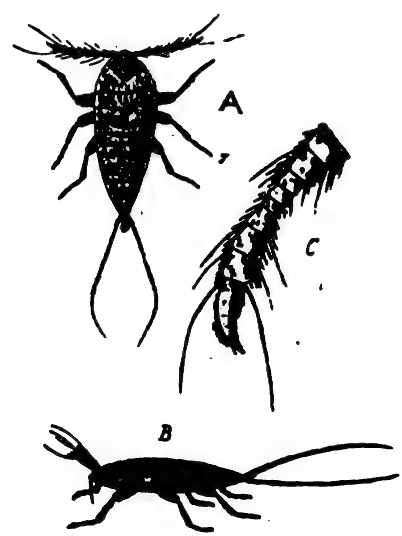
Origin of Lac.

Lac is a resinous excretion produced by a small insect. This insect, *Tachardia lacca*, belongs to the great order of insects known as the *Hemiptera*, or bugs, plant lice or scale insects. The most important characteristic of the members of this order is that they are furnished with powerful mouth parts, in the form of a piercing and sucking beak or proboscis. The family of the *Tachardia lacca* are the *Cocidea*. The majority of the members of this family are dangerous pests to crops and trees of many kinds, existing on the vegetable sap which they suck up through their probosces, which are inserted into the succulent tissues of the host. Coffee, tea, and other plantations alike suffer greatly at times from the ravages of these insects.

It is a curious fact that the lac insect should first be introduced to us as an enemy to cultivation, whereas, through the product of its depredations, it eventually obtains a high economic value. Nor does the lac stand alone as a useful member of the *Cocidea*, since another well-known scale insect, *Coccus cacti*, produces the red colouring matter known as cochineal; and *Ericerus pela*, a Chinese scale insect, secretes copiously a waxy matter that is used in the manufacture of candles in that country.

* * * * *

Fig. 1.



[illegible]

Let us suppose we have a tree infected with the lac insect somewhere in a grove by the side of an uninfected tree. About the first week in July the

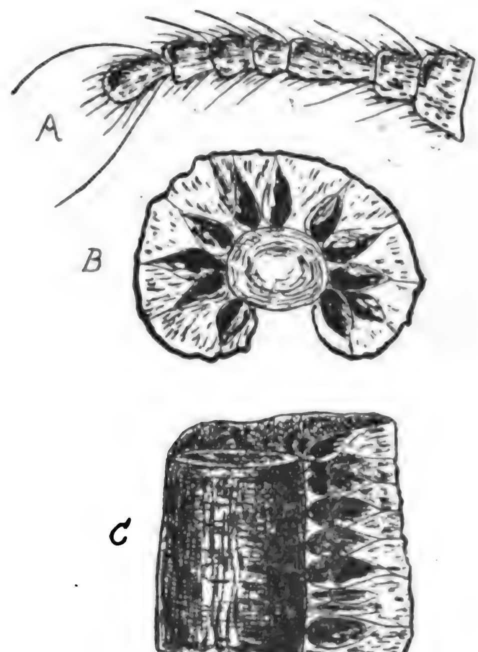
* Extracts from a paper read by Mr. A. F. Suter before the Paint and Varnish Society on March 11th, 1909.

larvæ begin to emerge from the incrustations on the twigs of the infected tree, and crawl away in quest of fresh feeding ground. They are then minute creatures of an orange red colour of elliptical shape, and measure about 1-40th of an inch. They resemble in appearance an ordinary bug, have no recognisable separation of body into head, thorax and abdomen, and are devoid of wings. They possess, however, six powerful legs, one pair of articulated antennæ, and a pair of small marginal eyes. Lastly, they have two very long white hairs that stand up at the anal extremity on the penultimate segment of the body. At this stage it is impossible to differentiate between the two sexes by the naked eye; in fact, the only distinction seems to be a difference in the articulation of the antennæ. For some 15 to 20 days the swarming continues, until the twigs assume quite a reddish colour and are literally alive with larvæ. The absence of wings prevents them from leaving the mother tree, so that the majority of them perish, being unable to proceed far enough by their own efforts to obtain new feeding ground, or else being incapable of piercing the bark of the twigs with the proboscis. The more fortunate ones are carried away to the other tree by the wind, birds, bees, and small animals such as squirrels and monkeys. Now the reason for the prolongation of the swarming period is apparent. Had it been completed in one day, climatic influences, such as heavy rain or total absence of wind, might have destroyed the whole brood.

As it is, let us assume that only a few larvæ have found their way to the neighbouring tree already mentioned, and there, on a soft sappy twig, fixed themselves on to the bark in a compact little colony. This little colony will now exclusively absorb our attention. The bark is punctured and the process of sap assimilation begins at once. In course of time we observe a light yellow, resinous incrustation forming round their bodies very gradually, which is due to the transformation of the plant sap—in the process of digestion—to a resinous excretion. While the insects are building their own prison, so to speak, they are undergoing structural changes all the while, the larvæ being gradually matured into the perfect male and female insects.

At a period of from 30 to 60 days after the swarming—that would be, say, from August 1st to September 1st — the incrustations are complete. The insects have totally disappeared from view, being now fully encased in the resin, and all that is apparent are innumerable tiny tufts of white hair or cotton filaments, covering the incrustations like a mould. What these filaments actually are we shall see later. If at this stage we break a portion of the incrusted mass open, we find it to be of a cellular structure, and that there are two kinds of cells, namely, a large circular cell, and, secondly, a smaller ovoid cell. The former are much more numerous than the latter, and contain the female insects. These cells are externally indicated by the white tufts above mentioned, while the smaller cells, containing the young males, are apparently without any opening. A closer inspection of these filaments, covered with white powder, will reveal that there are always three individual bunches close together, immediately above three tiny apertures in the incrustation. These three orifices are situated triangularly with respect to each other, two being closer to each other than the third, which is the largest and represents the anal aperture of the female insect, while the former two bunches of filaments are the attenuated extremities of the tracheæ (organs of respiration).

FIG. 2.



A Antenna of young female Larva
B·C Sections of a piece of Sticklack
showing rough arrangement of cells

Between the middle and the end of September the metamorphosis of the male insects is complete, and they begin to emerge from their cells. This they do by breaking the end of the cells open and crawling out backwards. They are then a little larger in size than the young larvæ at their exit from the parent insects, and are, by the naked eye, not easily distinguishable from them. Their structure, however, is different. They possess larger antennæ, which consist of nine or ten distinct articulations; four eyes, two lateral and two underneath the head; two long, hair-like appendages, covered with white powder, proceeding from the penultimate segment above, and a beaklike horny extension from the last segment, curved a little downwards and composed of two members, an upper and lower one, both grooved and

forming together a cylindrical channel, through which the semen is conveyed into the female.

The males, immediately after exit, exhibit an extraordinary energy and mobility, and can be seen busily engaged in crawling all over the incrustations, visiting the females. For some days the swarming of the males, as we may call it, continues. Each individual immediately proceeds to visit as many females as possible, after which function the male dies. Impregnation, therefore, seems to be the sole object of the fully developed male. The relative number of males to females has been calculated to be as low as 1 to 5,000, but, from the accounts of different observers, this proportion varies largely.

The encased female now undergoes a remarkable process of retrogression. The legs, antennæ, and the whole of the chitinous part of the body become almost indistinguishably incorporated with the surrounding resinous incrustation, so that on removal of the secretion, the insect appears again in almost a larval state. The abdomen of the female increases correspondingly, and becomes filled with an intensely red fluid, surrounding the ovary. This red fluid is the colouring matter, known as lac dye. The only other fully developed organ (besides the ovary) in the female body is the proboscis, which still goes on extracting the juice from the plant for the purpose of nourishment. I may state here that the exudation of the digested plant sap appears to be a viscid secretion from the anus of the insect. After impregnation the female insect goes on increasing for another three to three and a half months, when the new brood appears. The last month is evidently a period of rest, and during this time from all appearances, the insect lies dormant and abstains from food. The next stage, that is the issue of the new brood of larvæ during December, closes this interesting life cycle, which completes itself in a period of from four to six months. This explains the fact that certain parts of India, notably Mysore and Burma, yield not only two, but occasionally three crops per year, which is no doubt chiefly dependent upon the climatic and topographical conditions.

* * * * *

Manufacture and Commercial Aspects of Lac.

Cultivation.—As we have seen above, there are two yearly crops of lac in most parts of India, and, although the time of collection varies in the different provinces, the first crop generally falls between March and May, and the winter crop between October and February.

The lac is collected by natives exclusively, chiefly by forest villagers, who perform this operation in the most perfunctory way, taking little care for future crops, but often denuding the trees completely for the purpose of immediate gain. It is only in a few provinces where the collection of lac has attained considerable dimensions, that actual cultivation on scientific principles has been attempted, and as often or more by private enterprise than under the supervision of the Indian Forest Department. Here the trees are leased to the villagers, who engage themselves by contract not to remove more than 60 to 75 per cent. of each tree's crop, leaving the remainder for the purpose of seed; they are also bound to infect a certain number of fresh trees every year. This they do by lopping off, a few days before the swarming, some twigs covered with the healthiest incrustations, lightly wrapping them in a bundle of long grass, and tying them on to some sappy branches right up in the crown of some other tree. The grass is provided to assist the swarming larvæ to reach the new branches, and the seed twigs are placed so high that the insects which fall off on swarming may fasten themselves to the lower branches.

During the last twenty years many and extensive experiments have been made under the supervision of the Forest Department in various districts, but most of them have ended in utter failure. No doubt this is partly due to ignorance of the life cycle and other peculiarities of the insect on the part of the workers, but it must not be lost sight of that the insect itself has many more or less predacious enemies. Both birds and monkeys prey upon the insects, feeding either upon the new sweet lac or on the insect itself. Then there are ants of various species, swarming on the incrustations to lick up the sweet excrement exuded by the insects, which often destroy the whole brood affected. Furthermore, there are caterpillars belonging to the species of *Galleria* and *Emblemma*, which are known to hatch their larvæ in the new incrustations. Parasitic fungi may also grow on the lac, and by covering portions of the sticklac, kill off the animals situated underneath. Forest fires often destroy the crop of an entire district, and unseasonable heavy rain at the time of swarming of the young larvæ often does very great damage. Frost and hail are also extremely harmful.

As a general rule, the winter crop is almost always of more value to the grower, and it often happens that through adverse influences, as mentioned above, the summer crop produces no return whatever, but is barely sufficient for the propagation of the insect.

Collection and Manufacture.—The method of collecting the lac usually consists of breaking off the branches covered with incrustations, before the young larvæ have swarmed. This, of course, results in obtaining the lac cells, still containing the red colouring matter, which we know to be the lac dye, now no longer used. It has long been a moot point, whether this is the proper period of collection, since the lac dye has to be removed as thoroughly as possible before manufacture—in fact, to a certain extent, the value of the finished product is inversely proportional to the quantity of lac dye present; and it has naturally been suggested that the lac would probably be of superior quality if collected after the swarming of the new brood. Such a lac is actually in existence, known in India as "phunki" sticklac, but Dr.

Hooper, a Government official of Calcutta, has conclusively proved that this lac still contains a fair amount of this powerful colouring matter. In some localities, the incrustations are broken off from the twigs, which latter are left intact on the trees; or else the branches may be broken off, and then the resin detached by hammering with a wooden mallet before sale. In any case, the lac is then sold by the native collectors to the European or native middleman, who takes the article to the nearest factory.

Nearly the whole of the manufactured lacs of commerce may be said to be manufactured principally by hand in the neighbourhood of Mirzapore and Calcutta. In the factory, the lac-bearing twigs are broken into short lengths, technically called sticklac, either by hand or machinery. This sticklac is crushed by ordinary grain mills or by steam-driven roller mills. The resulting substance is then separated into three different masses, and graded as follows:—(1) Fragments of branches and twigs, used as fuel; (2) fine dust, consisting of minute fragments of lac and dirt, which is used for local consumption; and (3) granular lac, known in the trade as seedlac. This seedlac is then washed in tubs with a continuous supply of fresh water, at the same time being reduced to finer particles by treading or pounding. The wash-water becomes claret-coloured by the removal of the larger proportion of the lac dye, especially when the lac is being treated with a weak solution of sodium or potassium carbonate (in the form of crude plant-ashes). This washing extends over twenty-four hours. In the process of reducing the lac to a finer grain, a further quantity of a fine resinous powder is obtained, and this is also collected and sold for local consumption. After being washed, the seedlac is exposed on drying floors to the atmosphere and light, by which it is thoroughly dried. and, to some extent, bleached.

At this stage of the process the materials for adulteration are introduced, viz., yellow arsenic, commonly called orpiment, rosin, or both. The orpiment, which serves merely a mechanical purpose. makes the lac opaque, and imparts a rich, pale straw colour. It is introduced only into the manufacture of the finest grades of shellac. The admixture of rosin serves to lower the melting point of the seedlac. In order to obtain a satisfactory product, the lowering of the melting point is a desirable factor, and the use of a certain amount of rosin has, therefore, hitherto been deemed necessary by the manufacturers, 1 to 3 per cent. being the normal amount permissible.

The orpiment is ground to a fine yellow powder, then mixed with the seedlac, and the quantity of rosin and the whole mixture is then placed in very long, narrow cloth bags, 10 to 12 feet in length and 2 to 3 inches in diameter. These bags, when charged, are held by two persons above and between two rows of open coke or charcoal fires. The operators slowly twist the two ends in the opposite direction. The heat melts the lac, and the steady squeezing of the bag causes a continuous oozing from the portions exposed to the fires. In this manner the whole of the contents of the bag are eventually emptied, dripping from the bag on the floor between the fires, either into troughs containing warm water, or else on heated stone flags. Portions not equally or sufficiently melted are scraped up and returned into the next bag. The melted lac is taken up from the troughs or stones while still plastic by a third person and stretched into a thin sheet, from which all impurities, like fragments of wood or charcoal or ashes, are picked out. On cooling, this sheet is broken up, and constitutes the class of lac which we know as shellac. All dark-coloured and dirty portions are picked out, and the rest of the broken sheets graded according to purity and colour.

No portion of the lac is regarded as useless. The parings and fragments of every stage of the manufacture are thrown back for re-melting and made into fresh sheets. More highly coloured lacs are treated in the same manner, but pulled into thicker sheets, and then broken up. This is the garnet lac, while button lac, instead of being drawn into sheets, is allowed to drop from the bag on a smooth surface, where it cools and hardens in the shape of circular buttons, about ¼-inch thick, and of varying diameter. After the melting has been completed, the bags are boiled for the purposes of gaining the residuary matter, known in India as kiri-lac; from this two further inferior qualities of button or plate lac are made, chiefly for local consumption.

The above description applies to the hand-made native lacs. In modern factories, supervised by Europeans, where steam power is employed, the principles of manufacture remain substantially the same as those practiced by the natives, the difference being actually only an increase in rapidity and magnitude of production. Orpiment is not introduced into any machine-made shellacs.

The lac is now packed into wooden cases, which are covered with gunny, iron-hooped and marked. Cases of orange and garnet lac usually contain an average of two bazaar maunds (a bazaar maund equals 2 qrs. 26⅛ lbs.) net, while button lac is packed in cases of 3 maunds net. The manufacturer may be either under contract to supply the whole of the crop's output to one shipping agent in Calcutta, or else his stock may be bought up by several agents, who have the goods sent down by rail to the port for shipment.

Industrial use of Lac.—In India, lac enters largely into the agricultural, commercial, artistic, manufacturing and economic operations of the people. Large numbers of natives find employment in the work connected with the propagation, cultivation, collection and manufacture of the various grades of commerce. In the Indian villages it is used as a varnish or a colour medium by the wood-turner in the production of furniture, toys, boxes, platters, &c. The metal-worker employs coloured lacs for the ornamentation of metal work. The silver and gold-smiths use it to load hollow silver and gold wares, such as rings, dagger, and sword handles, &c., while more humble

personal ornaments, like bangles and anklets, are entirely made from it. Indeed, it is highly probable that one of the very earliest utilisations of lac was this very preparation of peasant jewellery. In the Punjab and other provinces, it is largely employed in the manufacture of painted pottery.

In Europe the industrial uses of this valuable product are not less varied, but, of course, these are well known, and I need hardly go further into the matter, beyond enumerating the different industries. Probably first and foremost in the consumption of the article stands the spirit varnish manufacturer; next comes the hat industry, where large quantities of lac are used for stiffening the felt, both in alcoholic and alkaline solutions. The maker of sealing-wax consumes a fair share of lac, while the article is also employed in the manufacture of insulating material for electrical appliances. The extensive application of lac in the comparatively young manufacture of gramophone records is said to be the reason of America's enormously increased consumption of late years, while in pyrotechnics lac is used in powder form, owing to the fine yellow flame it produces on ignition.

TURKISH LICORICE.

The licorice plant has been cultivated, according to precedence of date, in Spain, Italy, Greece, the Ottoman Empire, Russia, China, Turkestan and Persia. The yearly production of dry licorice is as follows:—Spain, 1,120 tons; Italy, 4,480; Greece, 2,240; Turkey, 33,600; Russia, 22,400; China about 600 tons; and Persia and Turkestan, 300 tons. In Asiatic Turkey, licorice root is found in sandy and damp places, more especially on lands near rivers. It is dug by peasants from depths of from 10 to 20 inches, and sold on the spot at prices varying between one farthing to a half-penny a pound. The licorice produced in the province of Aidin is said by the American Consul-General at Constantinople to be the best in the world. It was first discovered in 1848, by an Italian, who, in company with an Englishman, began the business of collecting and exporting it to the United States. There remains to-day only one of the factories for the making of licorice paste, that at Senke, which produces annually 4,500 cases of paste, each of 220 pounds. Within eleven years Smyrna, which is the seaport of the province of Aidin, has exported 288 million pounds of dried licorice and 18 million pounds of licorice paste. The product in the district of Aidin is increasing. During the three years, 1904, 1905, and 1906, the province produced an annual average of 25,395 tons of undried licorice root. Drying the root reduces its weight to 15,360 tons, of which 10,240 tons were exported to the United States, and 1,536 tons to France, Italy, &c., while the balance was transformed into paste in the country itself. The ground where the plant is grown is rented each year by the merchants who deal in this article. Upon payment of the rent, the tenants have the right to dig, and export the root during the interval between September and May. The digging and transport of the root is given by contract to the peasants, or the latter work by the day for the tenant. According to the temperature and the season, a labourer can dig from 80 to 150 pounds a day. The annual rent of the ground varies from one shilling and fivepence to three shillings and sixpence an acre. In the following provinces of Asiatic Turkey the plant is cultivated to a considerable extent. Aidin—in the valleys of the Meandere, and the Giediz, especially the cazas of Menimen, Magnesia, Akhissar, Kassaba, Salihlar, Alachehir, Senke, Aidin, Nazeli, Tchine, Karadja, Sou, Bosdoughan, Seraikieni, Denizli, Boldan, Bayindir, Tyre, Endemish, Milas, Makri; Syria and Aleppo—in the valleys of the Nehr Az, Aksu and the Euphrates; Beirut, Bagdad, Mamouret-ul Aziz (Harput), Bassorah and Jerusalem.

A NEW WAX PLANT.

It has been recently discovered that the candelilla plant contains wax of an excellent quality, and in sufficient amount to make it extremely valuable. The plant is found growing in the following States of Mexico: Tamaulipas, Coahuila, Nuevo Leon, Chihuahua, Durango, Zacatecas, Sonora, Sinaloa, Baja California, Jalisco, Puebla, and San Luis Potosi. The plant is described as growing to a height of from three to five feet, in the shape of stalks without leaves or thorns, as many as a hundred stalks springing from the same root. The stalks are about a quarter of an inch to half an inch in diameter. The American Consul at Tampico says that the plant also contains rubber, but not sufficient to make its extraction profitable. Of wax, however, it contains a high percentage, averaging from three and a-half to five per cent. The wax is of a light colour, very hard and has a high melting point, which places it in the front rank of all vegetable wax. Purified it will make, it is said, the best quality of candles, lasting, and giving a brilliant light. Dissolved in turpentine, it makes an excellent varnish, and it is also used for the manufacture of shoe polish. It it said to give more lustre than the high-priced Carnanba wax from Brazil, which is at present exclusively used for the latter purpose. Purified and moulded into phonograph records, the candelilla wax will register the sounds perfectly. Successful tests have also been made with reference to its adaptability for the insulation of electric wires. Another use for this wax would be its substitution for beeswax in pharmaceutical laboratories, where its hardness and higher melting quality in the manufacture of plasters and ointments, in which beeswax is now the principal ingredient, would, it is said, make it especially serviceable. This wax can be bleached perfectly white and burning it gives off an agreeable odour.

HOME INDUSTRIES.

The Cotton Outlook.—If the estimate of Messrs. Niell Brothers is near the mark, 13,000,000 bales of cotton represent the probable total of the season's takings by spinners, and 12,850,000 the actual consumption. Putting the crop at 13,550,000 bales, there will be a substantial addition to the world's stores. Discussing the prospects for next season, Mr. J. W. Soady thinks that, except in Texas, there will be some reduction of the acreage under cotton. In his opinion, the natural increase in the opening up of new land for cultivation year by year has been more than offset this year by the relatively large increase in food crops, and generally he believes that the South is being educated to the necessity of a diversification of crops. Meantime, the Master Spinners' Association have unanimously resolved to take a ballot of those spinning American cotton on the subject of short time. The proposal is to stop the mills each Saturday and Monday between July 10 and September 27. In this way it is hoped that flagging trade will receive some stimulus, it being admitted that the over-production of yarn is one cause of the unsatisfactory state of the market. It remains to be seen whether more than 20 per cent. of those with whom the decision rests are against the proposal, which cannot be carried unless 80 per cent. of the voting is in favour of it. Three months ago the trade was not willing to accept this measure of compulsory short time, but the continuance of unfavourable conditions may have changed opinion. If the spinners of American cotton determine on short time, it may be expected than an attempt will be made to get the spinners of Egyptian cotton into line, but at present they are divided as to lessening the output in a general movement. Manufacturers of piece goods are also not able to run short time as a body owing to want of organisation. There can be no question that the spinning trade is not paying at present, and extra stoppages at most of these mills, amounting to 186 hours during the next three months, is an obvious way of improving the margin. Assuming that these stoppages are brought about, as is most probable, there will still be a considerable minority outside the Federation working full time.

British Capital Abroad.—When recently the Prime Minister stated his belief that it was to the advantage of home industries that British capital should be invested in other lands sharp exception was taken to it, but in his paper read before the Royal Statistical Society, Mr. George Paish strongly supports the Premier's view. Mr. Paish says that the investment in the last sixty years of about £2,500,000,000 of British capital abroad has been one of the main causes of the vast growth of British trade and prosperity in the same period. By building railways for the world, and especially for the young countries, Great Britain has enabled the world to increase its production of wealth at a rate never previously witnessed, and to produce those things which this country is especially desirous of purchasing, namely, foodstuffs and raw materials. By assisting other countries to increase their output of the commodities they are specially fitted to produce, British industries have helped those countries to secure the means of purchasing the goods that Great Britain manufactures. Mr. Paish estimates that in the twelve months ended June, 1908, the new capital subscribed in this country for India, the Colonies, and foreign countries amounted to £110,000,000, and the amount for the year ended June, 1909, is estimated at £175,000,000, making a total of no less than £285,000,000 subscribed in the last two years.

Coal and Taxation.—Coal owners have much occasion for anxiety just now. The Coal Mining (Eight Hours) Act comes into force on July 1; as was shown in these Notes last week, it is already causing serious friction between masters and men, and it has yet to be shown that it will not add appreciably to working expenses, and so assist foreign competition, already very formidable. And now there is the Chancellor of the Exchequer's proposal to tax ungotten minerals. During the recent debates upon the Budget in the House of Commons the Chancellor observed that "there is no uncertainty at all as to what is meant by minerals." Few lawyers would assent to that proposition, but there can be no doubt whatever that ungotten minerals include the unworked coal deposits of the country. The Budget proposal is to impose a duty on the capital value of all undeveloped minerals at the rate of a halfpenny for every 20s. of capital value. Should the proposal become law every person who owns land under which minerals exist will be required to pay upon the assessed value of such minerals although he derives no income or return from them whatever. In the case of coal the question arises as to what depth it is really economical to work coal measures, and, therefore, to what depth beneath the surface should the claim for taxes extend. It is doubtful whether coal can be profitably worked much below 4,000 feet, but however that may be, the acceptance by Parliament of the Chancellor's proposal to tax ungotten minerals could hardly fail to react seriously upon the present cost of output. It is estimated the halfpenny tax would amount to over £5,000,000 per annum, and this would in fact be a duty on the coal which is actually worked.

Coal Exports.—It is a remarkable fact that notwithstanding the large quantity of shipping unemployed, and the shrinkage in consumption for industrial purposes abroad, the exports of coal from the United Kingdom for the five months ended May last exceeded by some 4,000 tons the exports for the corresponding period of 1908. In steam coals there was an increase of 190,000 tons on 17,900,000 tons. Yet most countries show decreased imports. The principal increases were to Italy from 3,455,000 tons to 3,820,000 tons; to the Straits Settlements from 98,532 to 200,295 tons, and to Chili from 236,000

to 331,852 tons. Probably the explanation is to be found in the uneasiness of consumers as to the course of events in Wales and Scotland which has led them to assure themselves of as much of the coal due to them under contract as they were able to store, and in the fact that this has been going on for some time, culminating in the present glut of tonnage in the Welsh ports, and the large exports from Scotland. Stocks are so large that if a strike should take place it would be a considerable time before much pressure for coal would be felt.

Miners and the Double Shift — At their meeting on Friday last the Miners' Federation passed a resolution against any reduction of wages in consequence of the Eight Hours' Act. A national conference is to be summoned in order to arrange common defensive action. It is not the men on piece rates who object to the Act. The hewers, who are paid by their output, expect to recoup themselves by increased activity during the shorter working day. The difficulty is with the men on day wages. It is believed that so far as South Wales is concerned the difficulty might be got over if they would consent to the double shift, but for reasons that are not very convincing they have hitherto refused to agree to it, though in many other districts it is already in operation. It will be impossible for South Wales to compete on equal terms with other districts where the expenses of working are lower unless the double shift is conceded. In many of the Welsh mines the men have so far to travel underground before they reach the face that not more than six hours per day of effective industry can be counted on. It is difficult to believe that the Welsh miners will persist in their opposition to the double shift if the masters are ready to meet them half way, as they are said to be, in regard to other matters in dispute.

Trackless Trolley Cars.—The Sub-Committee of the Leeds Corporation which recently visited the Continent to study the question of railless electric trolley cars has issued its Report, which speaks favourably of the system, and recommends its installation between Leeds and Farnley. The Report gives particulars of the working expenses of some of the Continental installations. With the Mercedes-Stoll system the overhead construction cost £1,690 per mile, the chassis (without bodies) for the cars £550 each, and the working expenses, including such items as taxes and repairs, amounted to only 4·52 pence per mile. At Milan, on the Filovia system, the cost of operation was 5·65 pence per mile. It may be gathered that the Continental services are somewhat below the standard expected in the neighbourhood of large English towns, where these costs would most likely be exceeded. The omnibuses employed on the Continent are mostly single deckers, with comparatively small seating capacity.

Australian Combed Wool. — Australia annually produces wool to the value of about £24,000,000, the bulk of which finds its way to the United Kingdom and the Continent. Most of it is in the greasy condition in which it left the sheep's back, the work of scouring and combing being performed in the countries to which it is sent. These two processes reduce the weight and bulk of the wool about two-thirds, but increase its value by at least 25 per cent., say £6,000,000, making the total value of the wool, if thus treated, about £30,000,000. Last month the first shipment of Australian combed wool ever exported left Sydney for Japan. Local manufacturers have for years made their own tops, but the possibility of an export trade was never considered. The shipment referred to above consisted of 200 bales, and a similar quantity will be despatched by every Japanese steamer leaving Sydney during the next few months. The Japanese purchasers of Australian wool have, hitherto, done their own scouring and combing, but they anticipate that the Australian export of tops to Japan will enable them to extend their markets in the East.

Fire Insurance with Profits.—Attention has recently been given in these Notes to insurance developments of one kind and another, and a correspondent now directs notice to what seems to him to be the anomaly that whilst the with-profit policy has been forced more and more upon life insurance companies by the demands of public opinion, fire insurance offices as a body have steadily withdrawn from this kind of business. At one time there were several companies in London which gave to their policy-holders some return on their policies should they make no claim against the company, but within the last few years these have been absorbed by other institutions, and taking fire insurance business as a whole the public have come to consider that after having paid the rates securing them against loss from fire they have obtained all the benefits from the operation that can be expected. There is now only one old insurance company doing a general fire insurance business on profit-sharing principles. This company—the Essex and Suffolk Equitable Insurance Society—has a record which may be called unique. Established as far back as 1802, it was formed on the mutual principle, but was not allowed to conduct business in the London area, or in Scotland and Ireland. It was a company with the county of Essex foremost in its title, yet owing to its constitution four-fifths of the inhabitants in that county were unable to insure with it! It was not until 1906 that an Act was passed through Parliament revising the constitution of the society, enlarging its capital, and removing all restrictions as to the area in which its business may be conducted. The principle on which the company has worked is to charge ordinary rates in most cases, and to repay to the policy-holders, in cash, at the end of every five years (subject to certain conditions as

claims for compensation) as large a proportion as can be afforded of the premiums paid. This bonus, for over 100 years, has ranged from 25 per cent. to 50 per cent., and for the past twenty-seven years the latter figures have been paid without a break. The result is, that every five years an assurant who has to pay £10 per annum to the society, has received in actual cash £25 as bonus. One cannot quite see why other fire insurance companies do not do something of the kind, even though in lesser degree.

CORRESPONDENCE.

PROPOSED CONFERENCE ON INDIAN ART.

Mr. Cecil Burns's paper on "The Functions of the Schools of Art in India" read before the Royal Society of Arts, Indian Section, on the 27th of last month, under the chairmanship of Sir Hubert Von Herkomer, discussed some important problems connected with the subject of Indian art—a subject which I venture to think has perhaps been too little attended to by our Society.

The reason of the scant attention which it has received is, no doubt, mainly this—that Indian art is a subject which can only be rightly dealt with by experts, who are few in number. The interest in Indian art manufactures and Indian industries is already great and growing; Indian art, pure and simple, which should be the basis of all, is studied and cultivated by a very few. It is well that the Government has recognised the importance of the matter by founding art schools in some of the important centres of the Indian continent, by attending to archæological remains, and, to a certain extent, to other artistic relics of the past; but the field is vast.

Among the cultured Europeans in India, while many have inclination, few have time to devote to the real study of this subject. In London, perhaps, where retired Anglo-Indians of leisure are to be found, where such societies as ours exist, and where presentments of Indian art (as well as that of other countries) are exhibited in these great national institutions—the British Museum, the South Kensington Museum, the Victoria and Albert Museum, the Imperial Institute, and the Indian Institute at Oxford—there are fields of study and opportunities for it, as good as are to be found in any centre in India.

Mr. Cecil Burns's paper was full and interesting on its particular branch of the subject, but those interested must have felt how wide the field was, and how much thought and fruitful discussion might most naturally grow out of topics touched on by the lecturer, and the suggestions made. While speakers who joined in the discussion afterwards were worthily selected to lead it, there were many present who could have made valuable contributions to it and whose experience eminently fitted them to inform and suggest.

I was led before leaving the hall to make a proposal which I am not without hope may bear fruit; and perhaps you will allow the preliminaries to be discussed in your columns. It is that there should be assembled in London a conference of Indian art. There is so much of interest, so many fields of inquiry, so much room for suggestions, that a short meeting would be of little use; two days, or perhaps three, each day with a session of 2½ or 3 hours, would be necessary to make a conference really useful. As above said, there are many in London interested in the subject, and some experts. A committee might be formed to select the readers of papers and leaders of the discussions, and also to prepare a small and very carefully selected collection of exhibits to illustrate papers and stimulate inquiries.

The philosophy of Indian art and its religious basis has recently found a most eloquent and enthusiastic exponent in Mr. E. B. Havell, formerly Principal of the School of Arts, Calcutta. Mr. Havell's theories and conclusions, based upon much research and set forth with dignity and grace of diction corresponding to his belief in his cause, form an important contribution to the study of Indian art, if only because he speaks from intimate knowledge, considerable research, and strong conviction of the soundness of the views which he sets forth. There are many, perhaps, to whom these views will not commend themselves, but all lovers of the subject must be well pleased that there has arisen one who can plead eloquently, and set forth in due array, as it were, in the court of artistic opinion, views which, perhaps, few expected to hear propounded in the defence of what is very generally regarded as grotesque and extravagant.

Besides Mr. Havell's sumptuous volume, which is eminently fitted to stimulate thought on the abstruser aspect of Indian art, public attention has been strongly drawn to the subject by the recent correspondence in *The Times*, and the deputation to Mr. Runciman, President of the Board of Education, about the Indian Collection at South Kensington.

There may, therefore, be said to have arisen at the present time a special interest in the subject which should make the occasion favourable for a conference on Indian art, which I venture to advocate.

W. COLDSTREAM.

69, West Cromwell Road, S.W.

OBITUARY.

GEORGE FREDERICK DEACON, LL.D., M.Inst. C.E.—Mr. George Frederick Deacon, of Coombe Wood, Addington, died suddenly at his office in Great George-street, Westminster, on the 17th inst. Born at Bridgwater in 1843, Mr. Deacon was educated at Heversham and Glasgow University. In

1865 he accompanied the Atlantic Telegraph Expedition on board the *Great Eastern* as assistant to Lord Kelvin, who was then acting as scientific adviser. At this time he had started practice as an engineer in Liverpool, and six years later he was elected borough and water engineer of that city. While holding this position he invented the differentiating waste-water meter. He resigned the position of borough engineer in 1879, and, devoting his attention to the water supply of Liverpool, in conjunction with the late Mr. Thomas Hawkesley, he completed, as engineer-in-chief, the first instalment of the scheme, which cost £2,500,000, in 1892. He started practice in Westminster in 1890, and became president of the engineering section of the Sanitary Institute in 1894. Three years afterwards he was chosen president of the mechanical science section of the British Association, which was then meeting at Toronto. He received the Telford, the Watt, and the George Stephenson medals of the Institution of Civil Engineers, and was the author of many addresses and writings on scientific subjects. The honorary degree of LL.D. was conferred upon him by his *Alma Mater*, and he served on the Council of the Institution of Civil Engineers. He joined the Society of Arts in 1874; he read a paper on "Constant Supply and Waste of Water," in 1882, and he took part in discussions on several occasions.

QUESTIONS AND ANSWERS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTION.

MATERIAL FOR DIE-SINKING.—I have been informed that there is a substance, derived from the metal, tantalum, which is exceedingly hard and tough, and would therefore prove very valuable for die-sinking and engraving, and I should be glad to know more about it, and to hear whether it is possible to obtain it. The metal itself, as far as I understand, is exceedingly soft and ductile, so the derivative must be some compound. Practical gem engravers are very much in need of a material with the hardness of a diamond, but without its serious defect of brittleness.—DIE-SINKER.

ANSWERS.

EMBANKMENTS OF THE RIVER THAMES (see pp. 343 and 655).—Referring to the communication of Mr. H. B. Wheatley on the above matter in the *Journal* of the 18th inst., it may perhaps interest "Londiniensis" to know that Captain Perry published, in 1721, "An Account of the Stopping of Daggenham Breach, with the Accidents that have Attended the same from the First Undertaking." This is a most quaint and original book, and is descriptive of the various difficulties he had to encounter with the river authorities of the day, which were almost as trying as the physical difficulties of stopping the breach. In the absence of definite records it is impossible to determine by whom the original embanking of the River Thames was carried out. It must not be forgotten that, by reason of the deepening and canalisation of the river, which has been going on for centuries, its character has doubtless completely changed since Roman times, when it was probably a sluggish stream meandering through a chain of swampy lagoons, and reclamation was consequently a less formidable undertaking. I have charge of about 15 miles of the Essex sea walls in the estuary of the Thames, and the material of which these walls is composed, and the method of their construction, indicate that the original embankers of the River Thames were thoroughly skilled in this difficult work. The character of other walls under my charge on the Essex coast reveals the same condition of things. It is difficult to find on the marshes now, clay of the character used in their construction, and the "wallers" have curious theories to account for this state of affairs. Stuart Moore's "History of the Foreshore and Law Relating thereto," and Hall's "Essay on the Rights of the Crown in the Sea Shore," contain much matter of historical and antiquarian interest as to the embanking of the River Thames.—A. E. CAREY, M.Inst.C.E.

WHITE LEAD AND WHITE LEAD PAINT (see p. 624).—The merits and demerits of white lead have been, at all times, a fruitful source of controversy. Whilst hundreds of processes for improving it have been devised in recent years, they have, for the most part, failed to justify their introduction commercially, and have only proved of service in providing padding for books, and for increasing the revenues of the Patent-office, and what is known as the "old Dutch process," which has come down to us, with but slight modifications, from the time of the Romans, still holds its own in a large measure. The opacity of white lead is one of its most important properties, and it is here that the old process excels, and most modern inventions fail. The objections to the old process, on the other hand, are the difficulty of control, the length of time required, and the great risk of lead poisoning to those engaged in its operation; it is the latter disadvantage which, under the stringent regulations of modern days, has stimulated efforts to devise an alternative

method. Although, as already mentioned, the majority of such methods have had but a short career, there are now in this country at least two which seem to be making headway against the dead-wall of prejudice in favour of the old method, which is characteristic of the users of this material, and which has certainly been justified by past history. The process devised by the late Professor Bischof, some twelve years ago, and now in operation on a large scale at Brimsdown, is exceedingly ingenious. In this process, the lead is oxidised to litharge, which is then reduced to sub-oxide, and converted into hydrate, from which the white lead is produced by partial conversion into carbonate by exposure to carbon dioxide. The advantages offered by this process may be summarised thus:—(1) The proportion between the hydrate and carbonate—on which the opacity of the pigment to a large extent depends—is subject to accurate control. (2) No free lead can be present in the product, or objectionable compounds such as basic acetate, and it is of uniform fineness and free from grit. (3) The operation being entirely automatic, and after the formation of the litharge carried on entirely in the wet state, it is very advantageous from the hygienic point of view. Unfortunately white lead made by this process, whilst excellent as a pigment, suffered from some defects as regards qualities which did not commend it to the practical painter. It is only fair to say, however, that patient research has to a large extent overcome these difficulties, and that the process seems to be becoming firmly established.

There is another process which is of more recent origin, and, in fact, is still to a large extent in what may be called the "industrial experiment" stage, from which, however, it is rapidly emerging. Apart from the difficulties attendant upon specific processes of preparing the particular compound known as white lead, it has inherent defects which no process can obviate, such as its highly poisonous nature, and its liability to be blackened by sulphur. Many attempts have therefore been made to replace it by another compound altogether, and Hannay's process is of this order. The principle of this process is the production of lead sulphate direct from the lead ore (Galena), the galena being sublimed in a furnace and oxidised whilst in the gaseous state, with the resultant formation of basic sulphate of lead in an extremely fine state of division, which has an opacity, the absence of which in earlier methods proved a fatal stumbling block to the substitution of this compound. My only objection to this process is that the product should be called white lead, seeing that it is an essentially different material from that connected by the use of centuries with this name. That, however, "is another story."

As regards books, despite the importance of this substance, there is no standard work entirely devoted to it. Most of the text-books on pigments, however, devote a considerable space to the discussion of white lead: Zerr and Rubencamp, for instance, in their "Handbuch der Farben Fabrication" (of which an English translation by Mayer has been recently published) give a very comprehensive account, although recent English and American processes are barely referred to. Petit ["Manufacture and Comparative Merits of White Lead and Zinc White Paints." English edition published by Scott, Greenwood and Son] enters fully into the question of white lead paint, although mostly from the controversial standpoint, and Maximilian Toch ["Chemistry and Technology of Mixed Paints"] discusses the technology of white lead in an able and up-to-date manner. The following may be interesting from an historical point of view:—Pulsifer, "Notes for a History of White Lead and Lead Oxides" [1888]; Faure, "Histoire de la Céruse" [1899].—N. H.

STAINED GLASS WINDOWS (see pp. 597, 625, and 655).—Referring to the further query on this subject by "L. F. D.," I certainly think it is far more likely that the introduction of the tint referred to was due to the use of cobalt than to a change in the fundamental composition in the glass. I scarcely think that this latter would account for such a striking difference, although the composition of the early mediæval glass was of such an exceptional composition that one hesitates to say exactly what may have been possible in the way of colouring it. Of course, if one postulates that the change *was* due to the introduction of cobalt, one is faced with the pertinent query made by "L. F. D." as to how the sapphire blue of the early glass was produced, and everyone takes it for granted, as "L. F. D" says, that this glass was covered by cobalt, but what I want to know is, on what is this assumption based? Appert ("Notes sur les Verres des Vitraux Anciens"*) speaks of this sapphire, as though he was quite sure it was coloured by cobalt, but unfortunately gives no indication as to how he arrives at this conclusion. I consider that it is quite conceivable that copper may have been the chromogen in this case, for the following reasons:—

(1) Compared with a normal cobalt blue, this blue is much further towards the red end of the spectrum; moreover, it is very much less intense—this can be very well seen in one of the medallions from St. Chapelle, in the Victoria and Albert Museum, where a piece of cobalt blue has been inserted in the seventeenth century. If, further, one considers that the early glass was something over twice as thick as the later, and was coloured throughout its thickness, it is evident that its colour was really very feeble.

(2) One can produce a pale blue of this type from copper in modern potash glasses.

(3) There was a fine blue pigment used in ancient times, and extensively in fresco painting. Davy, early in the last century, proved this to be a highly annealing glass like smalt, only coloured by copper

* The only book I know of which enters into the technology of mediæval glass.

instead of cobalt. It is evident, therefore, that under favourable conditions, we can produce strong blues with copper.

(4) The composition of early glass is, as I have said, exceptional: it differs from later glasses, not only in containing a very large proportion of potash, but also in having an extraordinarily high content of lime and alumina, the latter, according to Albert, reaching 8 per cent. (I am bound to confess, however, that I am somewhat sceptical as to his results). Now the colouration of alumina is a different matter from that of silicates. The colour of the ruby, for instance, is due to chromium, not copper or gold as one would expect from analogy with glass; and Verneuil, who has successfully reproduced rubies, has signally failed in his attempts to produce artificial sapphires by means of cobalt. It is possible, therefore, that this peculiar composition may have resulted in the production of colours in ancient glass which have no parallel in modern glasses. As I think one cannot be too careful in distinguishing between results based on theory and those derived from practical experiment, I conclude by once more emphasising the fact that all this is merely conjecture, and that nothing short of actual analysis would justify one in giving a definite answer to this interesting query.—N. H.

NOTES ON BOOKS.

The Arts Connected with Building. Edited by T. Raffles Davison. London: B. T. Batsford. 5s. net.

This volume consists of the lectures on craftsmanship and design which were recently delivered, under the auspices of the Worshipful Company of Carpenters, by Messrs. K. W. Schultz, C. F. A. Voysey, E. Guy Dawber, F. W. Troup, A. Romney Green, M. H. Baillie Scott, C. Spooner, Laurence A. Turner, and J. Starkie Gardner. The aim of the Carpenters' Company in instituting and publishing these lectures was neither antiquarian nor academic, but, in the words of the editor, "to stimulate the ambition of craftsmen towards a high ideal of attainment." The lecturers are all persons well-known for their study of practical craftsmanship, they are all eager to see a revival of the best traditions of the past, and they are all one in their desire that each craft—brick-work, plaster-work, wood-work, metal-work—should be raised to its highest level and co-operate harmoniously with its sister crafts for the attainment of that most desirable end, the house beautiful. The book is enriched with 98 illustrations—admirably reproduced—of old and modern work, and it is comforting to note that, although we cannot now-a-days rival the wonderful wood panelling of Magdalen College, Oxford (which forms the frontispiece), the wooden roof of Westminster Hall, or of the Great Hall, Hampton-court, there are signs that the arts and crafts movement has done "something definite to stir in people a belief in the value of beautiful craftsmanship." It is of vital importance that such a belief should be fostered, especially among the craftsmen themselves, and nothing could be better calculated to this end than the careful study of this volume.

Proceedings of the First International Refrigerating Congress. Paris: Secrétariat Général de l'Association Internationale du Froid. 3 vols. 25s. net.

The first International Refrigerating Congress was held at Paris from October 5th-12th, 1908, and the full report of the proceedings, which has just been issued, fills three thick volumes. The congress was divided into six sections, and the numerous papers and discussions now printed in English, French, German, and Italian, deal with refrigeration in all its aspects. The rapidity with which the trade in frozen food has grown is amazing. Whereas in 1880 the number of carcases imported was only 400, in 1902 the total from Australasia and the River Plate had risen to seven and a-quarter millions. Development on a corresponding scale has taken place in connection with the butter, cheese and egg trades, and much attention is now being directed to the problem of the cold storage of fruit. Possibly one of the most interesting of the papers is that by Mr. F. W. J. Moore, of Tasmania, upon this question. Tasmania, the Garden State of Australia, is a paradise of fruit, but the voyage is so long and the changes of temperature so great that the difficulties of landing such perishable cargo in this country in sound condition are enormous. In the case of apples, however—in spite of many failures at first—success has now been achieved, and Mr. Moore is not without hope that it will soon be possible to bring to our tables such delicate fruits as grapes, peaches and pineapples, "with all their pristine bloom and flavour."

MEETINGS FOR THE ENSUING WEEK

Tuesday, June 29...Faraday Society, Institution of Electrical Engineers, 92, Victoria-street, S.W. Annual General Meeting, 7½ p.m. Ordinary Meeting, 8½ p.m. 1. Dr. R. Beckett Denison, "Researches on the Relative Rates of Migration of Ions in Aqueous Solution." 2. Dr. Henry J. S. Sand, "Apparatus for the Rapid Electroanalytical Separation of Metals." 3. Mr. Samuel F[illegible], "The Conditions which Determine the Composition of Electro-deposited Alloys."

Wednesday, June 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.

Junior Institution of Engineers (at Fishmongers' hall, near London-bridge), 8 p.m. Lieut. A. Trevor Dawson, R.N., "The Engineering of Ordnance." (Gustave Canet lecture.)

Journal of the Royal Society of Arts.

No. 2,954. VOL. LVII.

FRIDAY, JULY 2, 1909.

All communications for the Society should be addressed to the Secretary, John street, Adelphi, W.C.

NOTICES.

CONVERSAZIONE.

The Society's annual conversazione took place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday evening, June 29th. The reception was held in the Central Hall of the Museum by Sir William H. White, K.C.B., F.R.S., Chairman, and the following members of the late and present Councils:—Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., The Lord Chief Justice, G.C.M.G., Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Sir William Bousfield, M.A., LL.D., Mr. Robert Kaye Gray, Col. Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., The Hon. R. C. Parsons, M.A., Sir Boverton Redwood, D.Sc., F.R.S.E., and Mr. Carmichael Thomas.

The following portions of the Museum were open:—The Central Hall, containing cases of specimens illustrating Mimicry; adaptation of colour to surrounding conditions; protective resemblance, &c.; the North Hall, containing the collection of Domesticated Animals; the Bird Gallery, containing groups of British birds and nests, &c.; the Fish Gallery, the Shell Gallery, and the East and West Corridors on the first floor.

Concerts were given by the String Band of H.M. Royal Engineers (conductor, Mr. Neville Flux, A.R.A.M.) in the Central Hall, and the Red Band, under the direction of Mr. Thomas Batty, in the Fish Gallery. A selection of songs, instrumental music, &c., was performed on the Auxeto-Gramophone under the direction of the Gramophone Company, in the Shell Gallery.

The number of visitors attending the Conversazione was 1,458.

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts, and Payments, during the past year, and also for the Election of Officers and New Members, was held in accordance with the By-laws on Wednesday last, 30th June, at 4 p.m., SIR WILLIAM H. WHITE, K.C.B., F.R.S., Chairman of the Council, in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the last annual meeting.

The following candidates were proposed, balloted for, and duly elected members of the Society:—

Adams, Arthur, 17, Blenheim-road, Bedford-park, W.
Ashcroft, Edgar Arthur, Assoc.M.Inst.C.E., Sande Gaard, Balestrand Sogn, Norway.
Bader, Frederick Robert, Assoc.M.Inst.C.E., 57, Chancery-lane, W.C.
Ballantine, W. J. H., Deputy-Magistrate, District Dinajpur, Eastern Bengal and Assam, India.
Black, David, 128, Upton-lane, Forest-gate, E.
Blundell, Thomas George, 30, Ferncroft-avenue, Heath Drive, Hampstead, N.W.
Cheney, Miss Elizabeth, The Needles, Peterborough, New Hampshire, U.S.A.
Clogstoun, Cuthbert George Wilder, Deputy-Inspector-General of Criminal Investigation and Railway Police, Madras, India.
Dickson, Archibald Allan Clifford, A.I.M.M., F.G.S., M.A.I.M.E., Rejoulie P.O., *via* Nawadah, E.I.Rly., Gaya District, India.
Dunscomb, Samuel Whitney, Junr., A.M., Ph.D., LL.B., 34, Pine-street, New York City, U.S.A.
Gourlay, William Robert, I.C.S., 8, Elysium-row, Calcutta, India.
Guggenheim, William, 500 Fifth Avenue, York City, U.S.A.

Hay, Alexander Mackenzie, "The Statist," 51, Cannon-street, E.C., and "Marston," Warlingham, Surrey.

Hoe, Robert, Junr., 113 East 55th-street, New York City, U.S.A.

Holmwood, Hon. Mr. Justice Herbert, Queen Anne's-mansions, S.W., and the High Court of Judicature, Calcutta, India.

Hulett, Hon. Sir J. Liege, M.L.A., J.P., Prince of Wales Hotel, De Vere-gardens, Kensington, W., and Pietermaritzburg, Natal, South Africa.

Huntington, Archer Milton, Audubon-park, West 156th-street, New York City, U.S.A.

Jeme Tien Yow, Taotai, Ph.B. (Yale, U.S.A.), Assoc.M.Inst.C.E., Imperial Peking-Kalgan Railway, Peking, China.

Law, Maharaj-Kumar Reshee Case, 8, New China Bazar-street, Calcutta, India.

Mitchell, Francis Henry O'Connor, B.A., Government School of Engineering, Insein, near Rangoon, Burma.

Nevill, James Forder, Bulmer, Burnt Ash Hill, Lee, Kent.

Nevin, Miss Blanche, Churchtown, Lancaster County, Pennsylvania, U.S.A.

Pike, Warburton, Union Club, Victoria, British Columbia, Canada.

Pollard, Herbert Edward, Public Works Department, Shanghai Municipal Council, Kiangse-road, Shanghai, China.

Preston, Arthur, 103, Clive-street, Calcutta, India.

Roberts, Charles T., M.I.Mech.E., Champion Reef, State of Mysore, India.

Ruthven, Dr. Jane Buchanan Henderson, M.D. (Brux), L.R.C.P. and S. (Edin.), Eagle's Nest, Johannesburg, Transvaal, South Africa.

Smith, Richard B., 407 West 57th-street, New York City, U.S.A.

Stuart-William, Albert L., Resident Engineer-in-Charge, D. H. Railway, Didwana, Jodhpore State, India.

Syfret, Stephen, M.D., Mowbray, near Cape Town, Cape Colony, South Africa.

van Deventer, Dr. C. Th., 20, Suriname-straat, The Hague, Holland.

Win, Maung San, Peterhouse, Cambridge.

Young, Colonel Sir John Smith, C.V.O., 13, Gloucester-street, S.W.

The CHAIRMAN nominated Mr. Noel Heaton, B.Sc., F.C.S., and Lieut.-Col. G. W. Macauley scrutineers, and declared the ballot open.

The SECRETARY then read the following

REPORT OF COUNCIL.

I.—ORDINARY MEETINGS.

The Session opened as usual with an Address from the Chairman of the Council. Sir William White commenced by referring to the assistance which was given by the Society to other kindred Associations, and especially to the Institution of Naval Architects, which for fifty years had held its annual meetings in the Society's hall, and in connection with which institution Sir William had first known the Society of Arts. From this indirect connection of the Society with the professional education of naval architects, the Chairman passed to a general consideration of the steps which had been taken in this country for the promotion of the technical training of those connected with naval matters, as shipbuilders, engineers, and naval officers. The record which he gave will serve as a valuable summarised history of the subject for future reference.

At the second meeting of the Session Sir Martin Conway gave an extremely interesting description of a part of South America which is perhaps less familiarly known to English people than almost any other district of that Continent—Bolivia and the part of Peru lying to the East of the Cordilleras, and the gold-fields of that country. In 1900 Sir Martin Conway read before the Society a paper on Bolivia, and on the present occasion he brought the information on the subject down to date, and showed how far the country, perhaps as rich as any part of the world in mineral wealth has been developed.

The next meeting was devoted to a paper by Mr. Eric Stuart Bruce, who was for some years secretary of the Aeronautical Society and who has given constant attention to the subject for a long time, on "Mechanical Flight." The paper dealt with the history of the subject, the early suggestions in 18[illegible] of Mr. Wenham, the experiments of Lilienthal (interrupted in 1896 by his death), and Sir Hiram Maxim's paper in 1894, down to the recent marvellous developments of the aeroplane by the Brothers Wright.

Next came a paper by Mr. G. Albert Smith on "Kinematography in Natural Colours." Since the cinematograph was first brought to perfection, it has been the aim of all those who were interested in it to apply to moving pictures some one or other of the various methods by which colour has been more or less satisfactorily added to photograph

pictures. When the three-colour principle was perfected and successfully employed, many inventors endeavoured to apply it to the cinematograph. In theory the task was not very difficult; but in practice it has always been found quite impracticable to give a sufficiently accurate register to three cinematograph pictures projected simultaneously upon a screen. Mr. Smith succeeded in solving the problem by using a single film on which alternate exposures were made through two filters, one of which allowed the orange and red rays to pass, and the other, the rays from green to violet, while both transmitted the yellow, and a certain proportion of white light. In practice, this system proved to be workable, and the result was shown in a number of cinematographic pictures, reproducing quite satisfactorily, and with very fair accuracy, the colours of nature. Since the reading of the paper, similar pictures have been exhibited in public, and there is no doubt that a very valuable addition has been made to the powers of the cinematograph.

The last paper, before the Christmas recess, was by Mr. Primrose McConnell, on Milk Supply. Mr. McConnell was able to speak with authority on the subject of pure milk supply, and he took up the cudgels on behalf of the purveyors of milk against some of the recent conclusions of the Royal Commission on Tuberculosis. It is probable that a good many medical authorities will not agree in theory with his views. On the other hand, there is not much doubt that the practical suggestions he made are well worthy of consideration, and it is to be hoped that they will be considered when the Bill on Milk Supply lately introduced into Parliament comes to be discussed.

The first paper after Christmas dealt with an artistic subject, "Gothic Art in Spain," and was read by Mr. Henry Brewer. Mr. Brewer gave an extremely interesting description of many of the principal Spanish cathedrals, and traced the development of Christian architecture in Spain as it grew out of the art established in that country by its Moorish conquerors.

In his paper on "The Part played by Vermin in the Spread of Disease," Dr. James Cantlie discussed the subject from the theoretical point of view, and showed how large a proportion of human disease is due to parasites, who pass a portion of their life history in the bodies of creatures other than man, some of them in insects and some in mammals. From this was drawn the obvious conclusion that human safety required the destruction of the original hosts of these disease-generating organisms.

The paper on "The Problem of Unemployment" by Mr. Bolton Smart, gave some account of the work which has been carried on at the Hollesley Bay Labour Colony under the Central (Unemployed) Body for London. Mr. Smart has been superintendent of the colony since its foundation, and he was consequently able to give a very full and accurate account of the results which had been attained, though his view was naturally biassed in favour of the work. The paper was very fully discussed, and the general opinion was that on the whole much valuable work had been done in training the unemployed of London for agricultural and garden work, although some of the speakers criticised those results and animadverted upon the cost at which they had been attained.

Mr. Archibald Colquhoun's paper on "Bosnia and Herzegovina" also gave rise to a rather animated discussion, in which very various views were expressed by speakers, representing some of the nationalities concerned. All, however, who took part in that discussion, realised the value of the information supplied by Mr. Colquhoun about a country, which, though now a centre of very great interest, is not familiarly known to many English travellers.

During the last few years, the Society has been singularly fortunate in securing the assistance of eminent Frenchmen in contributing to its Proceedings. In the Session of 1906-7, Monsieur Bunau-Varilla gave a most valuable paper on the Panama Canal, advocating the view, which, though it has not commended itself to the United States Government, has yet many who approve of it, that it would be better to cut a canal across the Isthmus at sea level, rather than to carry out the work in the form of the original scheme of a canal with locks. Last session, Monsieur Lucien Hubert gave the Society an account of the French system of colonisation, which, though it is entirely different from the English idea, yet offers many suggestions of importance. During the session which has just concluded, Monsieur Yves Guyot, the distinguished French economist, read an important paper on "The Commercial Relations of France and Great Britain." The principal point with which Monsieur Guyot dealt, was the probable effect upon international commerce of the

recently proposed modifications in the French Tariff. The chairman, Sir Robert Giffen, was hardly prepared to agree fully with the disastrous anticipations of Monsieur Guyot, but other speakers, especially Mr. Harold Cox, supported him, and thought that all possible pressure should be brought upon the French Government to prevent the carrying into effect on the lines proposed of the new tariff.

At the next meeting Mr. Clayton Beadle and Mr. Henry P. Stevens gave an account, mainly historical, of the manufacture of Hand-made Papers in different periods. Following this, at the first meeting in March, Mr. George Hubbard, in a paper on Dew-ponds, urged the importance of the utilisation of the application of what might be called the dew-pond system to the obtainment of water in arid countries. The paper gave rise to a great amount of discussion, both in the *Journal* and elsewhere, discussion which seems hardly yet to be concluded. The precise means by which a pond on the top of a high down, into which no surface drainage can flow, is kept full cannot yet be said to be absolutely settled, though it is difficult to imagine any other source than condensation of atmospheric moisture, whether in the form of what is known as dew, or from mist or fog. At all events there can be no doubt that the suggestions made by Mr. Hubbard as to the carrying out of experiments in rainless districts are well worthy of consideration, and that if even a moderate supply of water can be obtained by such means, the result will be of very great value indeed.

In the year 1897, in his course of Cantor Lectures on "Alloys," the late Sir William Roberts-Austen first brought under the notice of the Society the then novel method of investigating the structure of metals and alloys by a microscopic examination of their etched surfaces. Mr. Walter Rosenhain, to whose labours at the National Physical Laboratory much of the advance during recent years in this subject is due, told the Society in his paper on "The Application of the Microscope to the Study of Metals" how great those advances had been, and showed how important the power of examining the structure of such materials as commercial steel had proved, enabling as it did metallurgists to detect, and consequently eliminate, impurities in such articles as girders, crank-shafts, boiler tubes and rails, impurities which might eventually prove to be the cause of fracture.

By most people, even qualified musicians, the drum has always been looked upon rather as an instrument for marking and emphasising time rather than for the production of melody. The object of Mr. Gabriel Cleather's paper on "The Musical Aspect of Drums" was to controvert this view, and to prove, as he certainly did by his paper and by the illustrations with which he supplemented it, to those attending the meeting that the drum was in every sense a musical instrument, whose value for orchestral effects was far greater than was generally admitted.

For some years past a great deal of attention has been directed at the Society's meetings to the question of Timber Supply, and in the papers read in recent sessions by Sir Wilhelm Schlich, Sir Herbert Maxwell, General Michael, and Mr. Hutchings, the question has been very fully treated from different points of view. Dr. Nisbet's paper on "Afforestation and Timber Planting in Great Britain and Ireland" was, in the main, a criticism on the proposals for timber planting on a large scale included by the Royal Commission on Coast Erosion in their Report. At the same time, Dr. Nisbet was strongly in favour of a reasonable scheme of afforestation, provided sufficient attention was given to the conditions and requirements of the different parts of the country. In the discussion which followed, Dr. Nisbet's remarks on the Report were to a great extent endorsed, although there was, as might naturally be expected, some divergence of opinion as to the steps which should be taken for increasing the timber supply of this country.

Special attention has lately been directed to the island of St. Helena in consequence of the removal of the garrison from the island, and the disastrous effect which that removal is having upon its prosperity. Mr. J. C. Melliss, who is well known as having devoted a great deal of attention to the history and conditions of the island, gave the Society a very interesting account of it in the paper which he read here and urged the necessity of some steps being taken to revive its decaying fortunes, and to remedy the effects caused by the removal of the garrison.

In his paper on "The Resources of the Peruvian Andes and the Amazon," Mr. C. Reginald Enock may be said to have continued the subject which had been started at the beginning of the Session by Sir Martin Conway, the mineral and industrial resources of Western South America. Mr. Enock, who has already made a name for himself by th

valuable works which he has written on Peru, gave a very full account of the mineral and other resources which are now being worked in the district under consideration, and still await further development.

Mr. Percy Wells discussed in his paper on English Furniture the condition and prospects of the present manufacture of furniture in this country. He maintained that our designers and craftsmen were as capable now as in any previous era, but pointed out that the trade had to adapt itself to the changed conditions of modern production, in which of necessity machinery played a large part. Illustrating his remarks by a large collection of photographs of modern furniture, shown upon the screen, he demonstrated the excellence of the work which was now being produced by a number of manufacturers, both in the highest and most costly style of furniture, and in cheaper and simpler, but still excellent, cabinet-work.

The next meeting was devoted to the second Aldred Lecture. The conditions under which these lectures are given are stated in another paragraph of the Report. It is to be remembered that under the conditions of the Trust the subjects of the lectures are to be either scientific or literary. In the Aldred Lecture delivered last May Dr. Arthur Dendy, Professor of Zoology in King's College, London, gave a brilliant exposition of the Mendelian theory, and of the principles of heredity in their practical application to the production of new forms of plants and animals. The subject is by no means an easy one to make clear to a popular audience, but, difficult as it was, Professor Dendy certainly succeeded in his attempt within the space of an hour's lecture, to explain a scientific problem of very great interest and very great practical importance.

Considerable attention has lately been directed to the question of Railway Development in China, and Mr. Arthur Barry in his paper on that subject rendered a public service by the very full account he gave of the history and present condition of railways in that country. That railways will eventually be both constructed and worked by Chinese engineers and officials appears to be certain, but Mr. Barry's experience led him to believe that the time for this had not yet arrived, and that China must for some time to come be content to employ foreigners, both for the construction and the management of her railways.

The last paper of the Session dealt with a subject of very great economic importance and scientific interest. When Sir William Crookes, at the meeting of the British Association in 1898, suggested that before very long we should have to rely upon atmospheric nitrogen to supply the nitrates required for agricultural purposes, even his great reputation hardly prevented the suggestion from being treated as visionary. But there seems now very little doubt that Sir William Crookes' ideas are actually being realised at the present time. Herr Sam Eyde, who read to a large and interested audience on the 26th of May a paper on "The Manufacture of Nitrates from the Atmosphere," described the process which he and his partner, Professor Birkeland, have devised for obtaining nitric acid from atmospheric nitrogen by means of an enormous electric arc, and utilising that nitric acid for the manufacture of nitrates available as fertilizers. There seems no reason to doubt that the nitrate of lime produced by this method can compete both in manurial value, and in price, with the natural nitrate of soda, or the artificial sulphate of ammonia, which are now the fertilizing agents from which is supplied the nitrogen required by growing crops. The importance of the discovery it is difficult to overestimate, provided of course that further experiments on a commercial scale confirm the anticipations now held forth by the inventors.

II.—Indian Section.

The programme consisted of six papers, viz., "The Function of Schools of Art in India," by Mr. Cecil L. Burns; "The Birds of India," by Mr. Douglas Dewar, I.C.S.; "The Problem of Indian Labour Supply," by Mr. Selwyn Howe Fremantle, I.C.S.; "Some Phases of Hinduism," by Mr. Krishna Govinda Gupta; "The Buddhist and Hindu Architecture of India," by Professor Arthur Anthony Macdonell, Ph.D., and "Native Man in Southern India," by Mr. Edgar Thurston. With a single exception, all the above-mentioned contributors are actual members of the public service, and of these three are at home on furlough. Another has come to England on special duty, and the fifth is one of the two distinguished Indian gentlemen recently added to the Secretary of State's Council.

Mr. Dewar dealt in the first place with the general characteristics of the rich and interesting avifauna of the peninsula. He then devoted some time to various special features of Indian ornithology and to the consideration of certain phenomena which he maintains prove that "Wallaceism"

or the neo-Darwinian position is untenable. Finally, he referred to the depredations of the plume-hunter. During the Viceroyalty of Lord Curzon, an Act was passed prohibiting the export of plumage other than ostrich feathers, except as natural history specimens for museums. It is said, however, that the law is systematically evaded, and that the following Indian birds have recently been on sale in the London market:—Egrets (the "ospreys" of the feather trade), Impeyan or monal pheasants, paroquets, kingfishers, trogons, orioles, rollers, pittas, owls, jungle and peafowl, all (excluding the paroquets) "good friends of the Indian ryot." There is now before Parliament a Bill to prevent the importation of plumage into the United Kingdom, and if this measure is passed the Indian Act will probably be rendered more effective.

Professor Macdonell lately made a lengthened and important tour in India for the purpose of exploring the archæological remains of that country. His valuable paper embodied the main results of his examination of all the more distinctive of these ancient monuments, some of which are distant from the beaten tracks, and seldom visited by European savants. Professor Macdonell had many opportunities of seeing the beneficial effects of the much-needed Ancient Monuments Preservation Act, which India owes to Lord Curzon. One of the buildings which that Act is intended to conserve has a corridor in extent second only to that in the Vatican and 700 feet long. On a single band of the frieze of another structure visited by Professor Macdonell is a procession of 2,000 elephants, no two of which exactly resemble each other. Professor Macdonell claims to have demonstrated in his paper that while the Hindu temple of Southern India has been evolved from the *viharas* (monasteries) of the Buddhists, the Hindu temple of Northern India, as well as Buddhist temple architecture outside India, is a development of the *stupa* (relic mound).

Mr. Gupta began his singularly interesting paper by quoting some figures which, as he remarked, bring into prominent relief the important position occupied by the Hindus among the peoples of India, "an importance which is based not merely on their numerical superiority, but also on their material and intellectual progress." The population of the Indian continent is 294,000,000, and by religions it includes over 207,000,000 Hindus, 70 per cent. of the total. But Hinduism does not keep pace with its powerful rival, Islam, and would show an absolute decline in numbers but for large accessions of Animists. *Inter alia*, Mr. Gupta touched upon the social condition of the women of India, regarding whom, he says, there exists a great deal of misconception. It is asserted that they are immured within the walls of the zenana, where they spend their time in idleness and inanity. No picture could, he declared, be further from the truth. As regards the masses, constituting the bulk of the Hindu community, the women in most parts of India are as free as their sisters in Europe. Even among the better classes the zenana system is lax with the Hindus in Madras and Bombay; but whether the movements of Hindu ladies are restricted or not, they exercise an influence in family affairs which is far greater than is known here. With regard to the two great communities that seek to restore Hinduism to its original purity,—the *Brahma Samaj* and the *Arya Samaj*—flourishing branches of the former are now to be found in all parts of the country, and its adherents include some of India's most cultured and influential men. The *Arya Samaj*, though it has taken deep root in the Punjab is, however, still practically unknown in Bengal, Madras, and Bombay. "People in this country," Mr. Gupta says, "hear only of political unrest and of its various manifestations. They take little heed of the great religious upheaval that has overtaken the Hindu world, and of the various agencies that are at work for bringing about spiritual reform. From the earliest times the Hindu mind has been specially prone to religious impulses, and a Hindu above all is spiritual. His everyday life is mixed up with religion, and his care is more for the next world than for this. Hinduism is passing through a crisis which may well be described as severe, and it remains to be seen how far its powers of adaptation and assimilation, which have stood it in such good stead in the past, will come again to its help, and in what form it will ultimately emerge." Whatever happens, he holds that the descendants of so spiritual a race cannot drift into scepticism or irreligion. He hopes that the unsettling of beliefs caused by contact with the West will only be temporary, and that in future the religion of the Hindus will be "purged of all superstitious excrescences, and contain not only what is best in their own ancient faith, but also such precious gifts as the other noble

creeds have to offer, and that exclusiveness will give place to a wider sympathy and a truer recognition of the brotherhood of man."

Mr. Thurston's vivid account of the ethnographic investigations he has so successfully pursued in Southern India during the past eight years contained many new and interesting facts, especially with reference to the more backward tribes to be found in the Madras Presidency and neighbouring States. One of these tribes, the Pulayans, are, he says, the "most unpromising specimens of dejected humanity" whom he has come across, but civilisation "is fast bringing about changes in manners and customs which are sad from the ethnographist's point of view." Mr. Thurston expresses entire sympathy with the demand that selected candidates for the Indian Service should be required to take a course of study in the ethnology, sociology, and religion of the races among whom their life-work will lie.

In India, notwithstanding the density of the population—167 to the square mile—and the comparatively small number of large industries, the supply of efficient labour is not always equal to the demand. Not very long ago the attention of Government was urgently called to the matter by a Conference of Chambers of Commerce. In consequence of these and similar representations, Mr. Fremantle and another official were commissioned to visit the industrial and commercial centres of Bengal and Upper India to inquire into the causes of the scarcity complained of. It is chiefly from the experience gained in that inquiry, and from the discussions in which it resulted that the conclusions set forth in Mr. Fremantle's paper were formed. The normal growth of the population should be, in Mr. Fremantle's opinion, sufficient to provide all the labour required in the future, and recent improvements in communication have facilitated migration from the congested districts to the great industrial centres. Temporary difficulties may arise, but the Indian worker is tractable, teachable, and adaptable, and no fear need be felt that, "given fair conditions of labour and sympathetic treatment," there will ever be a serious shortage of labour in any field of industry. Coolie emigration, Mr. Fremantle showed to be, as far as the labour problem is concerned, a negligible quantity. British colonies, including Ceylon, contain nearly two million inhabitants of Indian nationality. But the average number of emigrants is now only 16,000 per annum, while about 9,000 return to India each year.

The experience of Mr. Cecil Burns, as Principal of the Bombay School of Art, has led him "slowly and unwillingly to the conclusion that although the artistic capacity of the people of India is present, the ancient craftwork of India is as dead as the art of the Greeks, or as that of the Renaissance in Europe." In his opinion, India must do for her artistic industries what Europe did long ago for hers and what Japan has recently done—transform them from an aggregation of isolated craftsmen to organised and skilfully directed combinations of workmen. With this end in view he urges the establishment by Government of a properly equipped central institution in which decorative work for public buildings can be designed and made. By this means the link which is missing in the educational chain that should join the Art School to practical craftwork would be supplied, a better standard of decorative work ensured, and a stimulus given to private enterprise in a field hitherto neglected by capitalists.

III.—Colonial Section.

"The Production of Wheat in the British Empire" was the subject of an important paper read by Mr. Albert E. Humphries, at the opening meeting of the Section, the President of the Board of Agriculture, Lord Carrington, occupying the chair. Mr. Humphries dealt exhaustively with the position and prospects of wheat cultivation in the United Kingdom, Australasia, Canada, India, and British Africa; discussed the "Rust Problem" in the light of his experiences as Chairman of the Home Grown Wheat Committee, and of the remarkable discoveries that Prof. Biffen has made at Cambridge by applying Mendelian principles to the greatest of the cereals, and concluded with some suggestive remarks on the effect of price on production.

Mr. J. Obed Smith in his comprehensive paper on "Canada as a Field for British Investment and Settlement" submitted that capital already invested in our North American possessions is safe and profitable; that the Dominion will continue to open up opportunies of securing investment for more capital; that the immigration of large numbers of new settlers, with small or large capital, is changing the economic conditions of the country, making investments more necessary, and, therefore, more secure; that American capital — and on this he laid stress—is seeking to control Canadian

industries; that there is more than a possibility of shipping Canadian grain, with profit, *viâ* Pacific ports to Great Britain; and that the probability of augmented commerce on the Pacific Ocean will attract capital, and warrant serious consideration. Mr. Smith expressed surprise that British capitalists should continue to be so largely interested in American railways and similar ventures when, owing to the limitations of the wheat-growing area in the United States, railway enterprise must to some extent be checked in the near future; while, on the other hand, railway construction in Canada "is not yet one-fifth of what will be required to develop Canada's resources to an extent equal to those in the States." In this connection he also mentioned that during the year 1908 the American Republic lost more people by emigration than it received by immigration. The chairman of the meeting, Lord Hindlip, observed that if any one believes that Canada is borrowing too fast or asking for more money than she can put up collateral security for, he had better go and see for himself. Those who have not been in Canada recently can, he added, form no conception of the progress that is being made every year and indeed every month. One of several Canadian visitors, who contributed to a useful discussion, warmly acknowledged the debt of gratitude which he said is owing to the Society for the opportunities it affords to people at home to realise the resources of the Empire.

In his valuable paper on "The Road to South African Union," the Hon. Charles Gideon Murray, of the Colonial Service, reviewed the various steps that have culminated in the present movement for unification, and showed how physical conditions have, despite all the influences tending to produce unrest and disunion, gradually compelled the people of South Africa to combine for their common benefit. With regard to the racial question between Boer and Briton, Mr. Murray thinks that it will be solved both by fusion of the two races and by an influx of immigrants of various nationalities. Interesting comments on the paper were made by Sir Godfrey Lagden, who presided, the Hon. Sir Lewis Michell, one of the members of the recent Conference which drew up the draft Act of Union, the Hon. Sir J. Liege Hulett of Natal, and others.

Nobody who heard or has read Mr. John Ferguson's admirable account of the splendid material and moral progress of Ceylon will be at all disposed to question the claim of the people of that fertile, beautiful, and enterprising island to be regarded as the leading Crown colony. It has now a population of 4,000,000; when it became a British possession there were less than a million inhabitants. At that time there were no roads worthy of the name; at present there are 3,000 miles of metalled, and 1,000 of gravelled roads, as good as are to be found in any part of the world. The record is, perhaps, less satisfactory with respect to railways, but that is owing apparently to what is considered by the planting community as the excessive caution of the authorities. The Colonial Office is now being pressed to sanction further lines, and Mr. Ferguson, as well as Sir West Ridgeway, who presided, strongly urged that the existing surplus of two million rupees should be used for this purpose rather than invested, as the Secretary of State has proposed, to form a reserve in case of some future and, as it is contended, extremely unlikely catastrophe, such as the ruin of the coffee industry by leaf disease a generation ago. The anticipated enormous increase, at a comparatively early date, in the value of Ceylon's rubber output, was advanced by Mr. Ferguson as one of the reasons why "Downing-street" should not delay any pressing schemes of railway and road extension.

IV.—Applied Art Section.

After very careful consideration, the Council determined in November last that the interests of the Society would in no way suffer if the Applied Art Section as a separate division of the Society was abolished, and its work merged in the general work of the Society.

The Section of Applied Art was established in 1887, and every Session since that date from four to six papers have been read dealing with subjects coming more or less within the scope of the application of Art to Industry. The definition has always been construed rather liberally, and the Section has been made to include papers dealing with artistic matters generally, as well as with Industrial Art. On the whole there can be no doubt that the contributions which the Society has received in this Section have included many most valuable and useful papers, and it is hoped that equally valuable papers will be read in future at the Ordinary Meetings of the Society, as indeed they were before the establishment of the Section. Since its establishment the Section has benefited by the

services of Mr. Wheatley as its Secretary, and his leaving the service of the Society offered a convenient occasion for the alteration.

V.—Cantor Lectures.

The Society has been fortunate in having a more than usually brilliant series of Cantor Lectures this year. The first course was on Explosives, by Mr. Oscar Guttmann, who is recognised as one of the highest authorities, at all events in this country, on the subject. Mr. Guttmann dealt with the progress which has been made in the manufacture during the past twenty years, and treated as fully as was possible in the course of four lectures the methods of manufacture of the various classes of explosives, and their several applications. Not the least interesting of the lectures was the one in which the use of explosives in mines was treated.

In the first course after Christmas, Mr. G. L. Addenbrooke dealt with the general question of Electric Power Supply, its cost, methods, and legal position. These lectures attracted a great deal of attention at the time of their delivery, and the suggestions made by Mr. Addenbrooke will certainly have to be considered in any future legislation on the subject.

In the third course, Mr. Leon Gaster dwelt with the whole question of Artificial Illumination, whether by electricity, gas, oil, or other illuminants. Perhaps no course ever given before the Society was so fully and elaborately illustrated. Mr. Gaster was able to secure typical examples of all the various methods of lighting which he described, and in fact each lecture was a concentrated exhibition of the best and most recent apparatus used for lighting by electricity, gas, and petroleum.

In the fourth course Mr. Gerald Stoney, who has been intimately associated with the firm of Messrs. Parsons in the construction and introduction of steam turbines, gave a most interesting account of the history of the Turbine from its origin down to its latest developments.

The fifth, and last, course was by Mr. F. W. Lanchester on Aerial Flight. There is perhaps no one who has made a more elaborate and careful study of the theory of the question than Mr. Lanchester, while his experience as an engineer and constructor of motors enabled him to deal fully with the practical side of the subject as well as the theoretical.

VI.—Juvenile Lectures.

In the long list of subjects which have been dealt with in the Juvenile Lectures since the first course was delivered here in 1874 by the late Frank Buckland, many topics have been brought before the Society, but nearly all dealt with some branch of science, or its practical application. This year the Council broke new ground by inviting Professor Waldstein to lecture on an archæological subject, and his two lectures on "Digging for Ancient Art Treasures," fully justified the experiment. Professor Waldstein gave a clear and graphic account of the methods which were pursued in investigating historic and prehistoric sites, and indicated briefly how great had been the effect on our knowledge of early history, which had been brought about by the investigations of himself and his colleagues.

VII.—Aldred Lecture.

The establishment of a series of lectures bearing this title was the outcome of a bequest by Dr. George William Aldred, a member of the Society, who died in 1868. He served with Her Majesty's army in India, graduated as M.D. of Paris in 1841, became a member of the Royal College of Surgeons in 1843, and was made a Fellow in 1859. At the time of his death he was resident in London. He bequeathed nearly all his property to public charities, mostly medical. Among his bequests he left a sum of £100 to the Society of Arts, in order that the interest might provide annually a £5 prize for an essay on some scientific or literary subject. The actual amount of the bequest (£90) was invested in Reduced Three per Cents—£97 16s. 6d. The interest on this was obviously insufficient to provide an annual prize of £5, and the Council consequently determined, in 1883, to allow the money to accumulate until there was sufficient to provide an annual sum of £5.

The total amount invested is now £220, which gives an annual income of over £6. Last year the Council determined that it could be more usefully employed in offering a fee for a lecture than a prize for an essay, while at the same time the presumed wishes of the testator would be carried into effect. They accordingly invited Sir William Ramsay to give the Society some information on his recent researches on radio-activity, and the brilliant lecture on "A Radio-Active Gas" delivered in December, 1908, was the result.

Wishing to vary the subject as much as

possible, they thought that this year they would endeavour to provide a discourse of a biological nature, and they were fortunate in securing the help of Professor Dendy, who in April lectured to the Society on "The Principles of Heredity as Applied to the Artificial Production of new forms of Plants and Animals." A reference to the contents of the lecture will be found in the portion of this report dealing with the Ordinary Wednesday evening meetings, at one of which it was delivered.

The Council hope that they may be able to continue the series of Aldred lectures either annually or biennially, as the funds may permit.

VIII.—Albert Medal.

The Council of the Society, with the approval of His Royal Highness the President, have awarded the Albert Medal of the Society for the current year to Sir Andrew Noble, Bart., K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

As far back as 1858 Sir Andrew Noble, then a Captain in the Royal Artillery, served as Secretary of the Committee on Rifled Cannon, and in the following year as Secretary of the Committee on Armour Plate and Guns. He had also become a War Office Inspector of Artillery when, in 1860, he joined Sir William Armstrong in the great Elswick firm, his connection with which has continued up to the present time. He has therefore very nearly completed half a century's work in association with the firm, and all that long time has been devoted to the investigation and improvement of the science of artillery. A great deal of this work was undertaken in collaboration with the late Sir Frederick Abel, but a great deal more of it was personal and original. The experiments which Sir Andrew Noble has carried out have ranged over every phase of the application of the science of artillery, practical, mathematical, chemical, physical, and historical. In his own words,* he has been associated "with all the great changes which have taken place, both as regards the guns, their mountings, equipments, and propellants, from the introduction of rifled artillery." His experiments include the firing of many thousands of rounds of artillery, and thousands of rounds in closed explosion vessels. They have dealt with the subject of pressures, velocities, and times, in the bores of guns and in closed vessels, also with the temperatures, composition, and decomposition of the gases, erosions, and detonations, as well as the chemical and practical examination of propellants and explosives of many kinds, and used by various nations.

To him is due the construction and use of the Chronoscope, the observations from which follow the motion of the projectile from the commencement of its motion to its leaving the bore of the gun. To his investigations are also due the arrangement and use of the Crusher gauge for recording the gaseous pressures during the passage of the projectile along the bore of the gun.

As a result of his experiments, makers of ordnance now possess chemical analyses and graphic illustrations, which provide a complete theory of ballistics, and indicate the chemical and dynamic action of the explosive during the period of its combustion. The whole theory of slow burning powder, by the action of which the pressure of the explosive is gradually increased, is due to the long series of experiments, the nature of which has been briefly summarised.

As long ago as 1877 the experiments of Sir Andrew Noble and Sir Frederick Abel caused an immediate reconstruction of guns and their mountings, and a return to breech-loading for British guns from the retrograde change to muzzle-loading which had some years before been adopted. From that date to the present time, all the many and great improvements which have been made in ordnance in this and in other countries, are to a very large extent due to the long series of experimental researches, carried out with persevering energy and unfailing ability by Sir Andrew Noble.

IX.—Medals.

The Council have awarded the Society's Silver Medal to the following readers of Papers during the Session 1908-9:—

At the Ordinary Meetings:—

To Mr. G. Albert Smith, for his paper on "Kinematography in Natural Colours."

To Mr. Henry C. Brewer, for his paper on "Gothic Art in Spain."

To Monsieur Yves Guyot, for his paper on "The Commercial Relations of France and Great Britain."

To Mr. George Hubbard, for his paper on "Dew-ponds."

* Preface to "Artillery and Explosives."

To Mr. WALTER ROSENHAIN, for his paper on "The Application of the Microscope to the Study of Metals."

To Mr. GABRIEL GORDON CLEATHER, for his paper on "The Musical Aspect of Drums."

To Mr. C. REGINALD ENOCK, for his paper on "The Resources of the Peruvian Andes and the Amazon."

To Mr. PERCY A. WELLS, for his paper on "English Furniture Design and Construction."

To Mr. ARTHUR JOHN BARRY, for his paper on "Railway Development in China."

To Herr SAM EYDE, for his paper on "The Manufacture of Nitrates from the Atmosphere by the Electric Arc."

In the Indian Section :—

To Mr. DOUGLAS DEWAR, for his paper on "The Birds of India."

To Mr. ARTHUR ANTHONY MACDONELL (Boden Professor of Sanskrit, Oxford), for his paper on "The Buddhist and Hindu Architecture of India.'

To Mr. SELWYN HOWE FREMANTLE, for his paper on "The Problem of Indian Labour Supply."

To Mr. KRISHNA GOVINDA GUPTA (Member of the Council of India), for his paper on "Some Phases of Hinduism."

To Mr. CECIL L. BURNS (Principal, Bombay School of Art), for his paper on "The Functions of Schools of Art in India."

In the Colonial Section .—

To the HON. CHARLES GIDEON MURRAY, for his paper on "The Road to South African Union."

Of recent years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers :—In the Ordinary Meetings the papers by Sir W. Martin Conway, on "The Goldfields of Eastern Peru and Bolivia," and by Mr. Archibald R. Colquhoun, on "Bosnia and Herzegovina;" in the Colonial Section, the papers by Mr. Albert E. Humphries, on "The Production of Wheat in the British Empire," and by Mr. John Ferguson, C.M.G., on "Ceylon: its Industries and Material Progress."

The Council, however, desire to express their high appreciation of these papers by thanking their authors for them.

The brilliant lecture delivered, under the Aldred Trust, by Professor Dendy, was not considered to be eligible for a Medal, though it occupied one of the Ordinary Meetings.

X.—SWINEY PRIZE.

In accordance with the provisions of the will of Dr. George Swiney, the prize bearing his name was duly awarded in January last, on the sixty-fifth anniversary of the testator's death. Dr. Swiney died on the 20th January, 1844, and in his will he left the sum of £5,000 Consols to the Society of Arts, for the purpose of presenting a prize, on every fifth anniversary of his death, to the author of the best published work on Jurisprudence. The prize was to be a cup of the value of £100, and money to the same amount; the award to be made jointly by the Royal Society of Arts and the Royal College of Physicians.

A meeting of the adjudicators of the prize was held on Wednesday, January 20, 1909, under the presidency of Sir William White, K.C.B., F.R.S., Chairman of the Council.

The adjudicators received a report from the joint Committee of the Society of Arts and the College of Physicians, recommending that the prize should be awarded to Dr. Charles Mercier, for his book, "Criminal Responsibility," and they adjudged the prize in accordance with the recommendation.

Under the existing understanding between the College and the Society, the Prize is given alternately to a work on General Jurisprudence, and to one on Medical Jurisprudence.*

XI.—OWEN JONES PRIZES.

After the death, in 1874, of Owen Jones, a committee was formed to collect subscriptions for the purpose of founding a memorial, and the balance (a sum of £400) was presented to the Council of the Society of Arts upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in actual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes have now been awarded annually since the year 1878 on the results of the annual competition of the Science and Art Department, and its successor, the Board of Education.

Six prizes were awarded last session (1907-8), each prize consisting, in accordance with the regulations prescribed for the administration of

* A list of previous recipients was given in the *Journal* of November 27th, 1908. Such information as is available about Dr. Swiney and his life will be found in two articles in the *Journal* of June 23rd, 1899, and April 16th, 1909. An account of the cup was published in the *Journal* on the last-named date, and an illustration appeared in the issue of June 24th, 1904.

the Trust, of a bound copy of Owen Jones's "Principles of Design," and a Bronze Medal.

The list of the successful candidates has already appeared in the *Journal*.*

XII.—Mulready Prize.

After the death of Mulready, in 1863, a fund was formed to establish a memorial to him. Sir Henry Cole was treasurer of this fund. The greater part of it was expended in erecting a monument over Mulready's grave in Kensal-green Cemetery. This monument is in the charge of the Society, and from time to time small sums have been expended on its cleaning and restoration. The balance, £109, was presented to the Society of Arts with the view of a Mulready Medal being presented occasionally to the student who should exhibit the best drawing from the nude at the annual examinations of the Science and Art Department, now the Board of Education.

The Medal has been awarded on several occasions, the last being in 1903. In April, 1907, it was announced in the *Journal* that a gold medal, or a prize of £20, would be offered for competition among students of Schools of Art in the United Kingdom, at the annual competition of last year.

The award was duly made on the recommendation of the Examiners of the Board, and was announced in the *Journal* last October.†

XIII.—Stock Prize.

In 1871 John Stock left £100 Consols to the Society, with the condition that the interest should be applied for the promotion of drawing, sculpture, and architecture. From time to time, as the accumulated funds permitted, prizes have been awarded under the Trust. In 1893, and again in 1897 prizes were offered to students in Schools of Art for architectural designs. A Gold Medal, or a prize of £20, was again offered for competition among the students of the Schools of Art at the annual competition of 1908 for "the best original designs for an architectural decoration, to be carried out in painting, stucco, carving, mosaic, or any other process suitable for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or part of the interior of a building."

The award, which was made on the recommendation of the examiners of the Board of Education, was announced in the *Journal* in September last.*

XIV.—Fothergill Prize.

In the year 1907, the Council decided to offer under the Fothergill Trust, a Gold Medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious, the object being to encourage the production of a rescue apparatus which would enable a succouring party to reach men cut off—in case of mining accidents—by irrespirable gases, or suffocated by them. It was known that many such appliances existed, but it appeared uncertain which of them were the best, or even which were of practical use.

In response to the offer a number of appliances were submitted by the specified date (March, 1908), and the Council appointed a Committee to deal with them. It was intended that all the apparatus sent in should be submitted to practical trials, but it was hoped that this might be done and the award made without any very great delay. It turned out, however, that a large experimental gallery, with the use of which the Council had hoped to be favoured, was not ready and indeed is not yet available, and the Council have, therefore, reluctantly been compelled to postpone the contemplated trials. The delay is, however, less to be regretted, because on the one hand there have been recent rapid improvements in details of the various apparatus which it is very desirable, if possible, to take into account, and on the other there has been a considerable increase of knowledge as regards the points of greatest importance in the apparatus.

XV.—North London Exhibition Trust.

In 1865 the Committee of the North London Working Classes and Industrial Exhibition (1864) presented to the Society a sum of £157, the balance of the surplus from that Exhibition, with a view to the annual award of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society. These competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. In 1903 it was found that the funds had accumulated, and accordingly it was determined to make a special offer of prizes of the value of Fourteen

* See *Journal*, vol. lvi., p. 915, 9 Sept., 1908.

† See *Journal*, vol. lvi., p. 1013, 23 October, 1908.

* See *Journal*, vol. lvi., p. 929, 11 September, 1908.

Guineas to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell. These prizes were continued annually to 1908. As by that time the accumulation was nearly exhausted, the Governing Body of the Institute were offered the choice between annual prizes of smaller value, and occasional prizes of the amount above mentioned. They selected the former, and therefore a sum of £5 will be annually devoted to the purpose until further notice. Prizes of that value were accordingly offered and awarded for the current year.

The results of the award were published in the *Journal* last April.*

XVI.—Prizes for Drawing.

Since 1889, the Council have annually placed at the disposal of the Royal Drawing Society, for competition among the candidates at its annual examination, 12 Bronze Medals, and these medals were awarded for drawings sent in by students to the exhibition held by the Drawing Society in April last.

Though these medals have been provided now for a period of twenty-one years, it must not be understood that the offer is certain to be continued. The question has been under the consideration of the Council, and notice has been given to the Royal Drawing Society that the award of medals may be discontinued at any time, the offer being only an annual one.

XVII.—Examinations.

As in recent years, it is proposed to postpone any detailed report on the year's examinations, until the results have all been issued. The Results of Stage III., Advanced, were published on June 17th. It is hoped to publish the results of Stage II., Intermediate, during July; and of Stage I., Elementary, early in August.

The total number of papers worked was 29,020, the number last year being 25,805, an increase of 3,215. These were divided among the various Stages as follows:—Stage I., 11,074; Stage II., 12,513; Stage III., 5,433. The corresponding figures for 1908 were—Stage I., 9,811; Stage II., 11,199; Stage III., 4,795. The increase is spread over all the Stages.

XVIII.—Viva Voce Examinations in Modern Languages.

Up to the present date 17 examinations have been held this year in London, Guernsey, Hitchin, and Manchester. Arrangements have also been made for holding examinations at several other centres.

At these examinations 366 candidates presented themselves, of whom 285 passed (96 with distinction) and 81 failed. The languages taken up were French, German, Italian, and Spanish.

The results of previous years are as follows:—

Year.	Number Examined.	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175
1907	629	476	153
1908	615	467	148

These examinations are held at any of the Society's centres where the necessary arrangements can be made, at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and the examination is so arranged as to test efficiency in a colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners, receive a certificate of having passed with distinction.

The examiners are Mr. S. Barlet for French, Professor H. G. Atkins for German, Professor R. Ramirez for Spanish, and Mr. Luigi Ricci for Italian.

The numbers this year, when all the examinations are finished, are not likely to show any considerable difference from those of 1908.

XIX.—Practical Examinations in Music, 1908.

The practical examinations in Music were not concluded last year until the 4th July, too late for the results to be included in the Report of the Council. They lasted for 10 days.

The examination was conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this

* See *Journal*, vol. lvii., p. 510, 24 April, 1909.

list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 440 candidates entered, and of these 432 were examined, a decrease of 25 as compared with the previous year. There were 333 passes and 99 failures.

The following were the subjects taken up:—Piano, singing, violin, violoncello, and viola. 330 entered for the piano, 243 of whom passed; 86 entered for the violin, of whom 76 passed; 2 entered and passed for the violoncello; 12 entered for singing, of whom 10 passed; and 2 entered and passed for the viola. Two medals were awarded.

XX.—Practical Examinations in Music, 1909.

The Practical Examinations for the present year have not yet been concluded. They commenced on the 22nd June, 1909. They will be finished on July 3rd, after which a summary of the results will be given in the *Journal*. The work of the examination is being carried out by the same examiners as in the last eight years. 400 candidates have entered for the present examinations, a decrease on last year of 40.

XXI.—Cobb Memorial Fund.

In the year 1901, after the death of Mr. B. Francis Cobb, who had served on the Council in various capacities since the year 1875, a fund was subscribed for the benefit of his widow, who was left in rather poor circumstances. It was arranged that at the death of Mrs. Cobb the portion of this fund which had been given by Members of the Society, or collected by its Secretary, should be returned to the Society of Arts to be dealt with as the Council might decide. The amounts contributed by Members of Lloyd's were in like manner to be passed on to Lloyd's Benevolent Fund. Mrs. Cobb died in March of the present year, and the Trustees of the Fund handed to the Society's Treasurers the amount of £248 17s. 4d., the proportion realised from the sale of the securities in which the money had been invested.

The Council, after careful consideration, decided that the money should be employed to establish a permanent memorial to Mr. Cobb, and that for the present it should be devoted to the establishment of an occasional lecture, or course of lectures—the disposition to be varied from time to time, as the Council might determine.

XXII.—Chadwick Trust.

Under the provisions of the will of Sir Edwin Chadwick, who died in 1890, the Royal Society of Arts nominates a member of the Trust established by Sir Edwin for certain purposes connected with sanitary education and the advancement of sanitary science. The Trust was formed in 1896, and Sir Douglas Galton was appointed to represent the Society of Arts. After the death of Sir Douglas Galton in 1899, Mr. Brudenell Carter acted as the Society's representative, and he was succeeded in 1904 by Sir William Abney, who was then Chairman of the Council. Sir William Abney's term of office having expired this year, the Council decided to appoint the Society's Secretary to act as its representative.

XXIII.—London Institution.

It will be remembered that in 1904 a proposition was made by the Board of Managers of the London Institution to the Council of the Society of Arts that a scheme for the amalgamation of the two bodies should be considered. A Joint Committee was appointed and a draft scheme proposed. This scheme was submitted to a meeting of the Proprietors of the Institution in the spring of 1905, but no vote was taken upon it, and no definite action followed. The Council of the Society therefore determined to abandon the idea so far as they were concerned, and discharged the Committee which they had appointed for its consideration.* In the latter part of last year the Board of Managers of the London Institution again took the question up, and decided to bring it for a second time before the Proprietors. No official communication on the subject was made by the Institution to the Society; but the Council of the Royal Society of Arts naturally regarded with benevolent interest the renewal of a suggestion which they always thought would be to the advantage of the individual members of the two bodies, and also to the public.

The first step taken by the Board of Managers was to recommend to the proprietors the scheme for amalgamation, and to ask their opinions by post-card. As the result of this enquiry, proprietors representing 526 shares expressed themselves in favour of the amal-

* See Reports of the Council, 1904-5 and 1905-6: *Journal*, 30th June, 1905, vol. liii., p. 847, and 29th June, 1906, vol. liv., p. 824.

gamation, and 84 were opposed. In February a special meeting of the proprietors was held, followed by a ballot. The result of the ballot showed 322 votes in favour, and 218 against. At the annual meeting of the Institution held in April, it was announced that the Royal Commission on University Education in London had intimated that they regarded the Institution as coming within the scope of their enquiries, and that, in the opinion of the legal adviser to the Institution, Parliament would not pass any Bill dealing with an Institution which was under the consideration of a Royal Commission. In these circumstances, no further action was taken, and the proposal was shelved for the second time.

At the Annual Meeting, as well as at the special meeting, a good deal of opposition was manifested on the ground that the amalgamation scheme would involve the removal of the Institution from within the City boundaries, and as the opposition seemed to show greater energy than the advocates of the change, it appears unlikely that, whatever the Commission may report, any proposal for amalgamation between the two Institutions will now be carried into effect. The Council cannot but regard with regret this abandonment of a scheme which promised to endow London with a powerful and well-to-do Institution by which the work, hitherto carried on by the two bodies for a century and a-half and a century respectively, might have been continued to their own greater advantage and with extended benefits to the country.

XXIV.—Honorary Royal Members.

In November last His Royal Highness the President of the Society, at the request of the Council, invited His Majesty the King of Sweden to become an Honorary Royal Member, a request to which His Majesty was pleased to accede. His Majesty's father—King Oscar of Sweden and Norway—was one of the first two Honorary Royal Members of the Society elected in 1876, His Majesty the King of the Belgians being the other.

XXV.—List of Members.

The number of life and subscribing members on the Society's books is 3,490, this includes a few Institutions in Union who subscribe from their own funds. The number of new members elected during the year was 280; the losses by death and resignation amounted to 355.

During the last forty years the number of the Society's members has not varied within very wide limits. In 1870 there were a little over 3,200; this rose in 1875 to 3,800. The numbers fell to 3,300 in 1881, and rose again to 3,656 in 1885. By 1899 the numbers had fallen to 3,078, rising again in 1900 to 3,123. After that there was a continuous increase up to 3,722 in 1906. Since that date the numbers have fallen away, and now, as above stated, the total is 3,490.

In 1850 the numbers were a little under 2,000. The increase in the twenty years succeeding 1850 was doubtless due principally to the great exhibitions of 1851 and 1862.

The number of Institutions in Union was much larger before the Examinations were thrown open. There are now in all only 18 Institutions in Union with the Society. Forty years ago there were about 150.

One feature in the present list is the large proportion of members residing in the colonies and in foreign countries. There are now few parts of the world in which the Society is not represented, while the number of Indian and Colonial members is very considerable.

XXVI.—New Council

The four Vice-Presidents who retire on account of seniority are Sir William Crooks, Mr. Robert Kaye Gray, Sir Philip Magnus, and Mr. Alexander Siemens. In their place the Council propose for election Sir Henry Hardinge Cunynghame, who, as an Ordinary Member of Council, has rendered the Society very active service, Lord Curzon, the Earl of Rosebery, and Lord Blyth, all of whom have served previously as Vice-Presidents.

The four Members of the Council retiring either from seniority or least attendances are Mr. Michael Carteighe, Sir Henry Cunynghame, Sir George Gibb, and Mr. H. Graham Harris. To fill the vacancies caused by these retirements, the Council suggest Dr. Henry Bovey, who, after many years service as a Professor and as Dean of the Faculty of Engineering at the McGill University, Montreal, has lately been appointed Rector of the Imperial College of Science and Technology; Mr. W. H. Davison, a Member of the London County Council Education Committee; Sir Robert Hadfield, a Past-President of the Iron and Steel Institute, and head of the well-known Sheffield firm to whom are due many of the recent improvements in steel manufacture; and Sir Richard Temple, who has contributed valuable papers on two occasions to the Society. None of these four gentlemen has ever served on the Council before.

XXVII.—CONVERSAZIONE.

The Conversazione for the present year was held on Tuesday last, the 29th inst., at the Natural History Museum, South Kensington, the Trustees of the British Museum having kindly granted this privilege to the Society. The last occasion, previous to 1908, on which the Conversazione was held at the Natural History Museum was in 1900, the Conversazioni from 1901 to 1907 having been held in the Gardens of the Royal Botanic Society. An account of the Conversazione for this year will be found in the present number of the *Journal*.*

XXVIII.—CHANGES IN THE STAFF.

Shortly after the close of the last Session Mr. H. B. Wheatley, who has been Assistant-Secretary of the Society since March, 1879, intimated to the Council his wish to retire, and in view of the length of his service and his time of life, the Council felt bound to accept his resignation, though they did so with very much regret. The Council were glad to secure the services of a capable successor to Mr. Wheatley in the person of Mr. G. K. Menzies, who has had considerable experience in the Central Office of the University of London.

Some of the present and past members of the Council of the Society subscribed for a testimonial to Mr. Wheatley, which took the shape of a piece of plate and a cheque, and was presented to him at the Council meeting on the 15th of March last by the Chairman of the Council, Sir William White, on behalf of the subscribers. Mr. Wheatley was also elected a life member of the Society under By-law 61, which empowers the Council to elect annually a certain number of life members free of all dues.

The finances of the Society, unfortunately, do not permit the Council to recognise the services of old and valued officials in their retirement; but, in the case of Mr. Wheatley, it was felt that a moderate pension should be voted to him.

XXIX.—OBITUARY.

It must be very many years since the Society has had to deplore the loss in a single year of so many of its members who were actively employed in carrying on its work. Since the last annual meeting the Council has lost no less than three of its most active members. Sir Charles Kennedy died in October, having been re-elected on the Council, after many years' previous service, at the last election. He was for ten years chairman of the Colonial Section, twice read papers before the Society, and was a regular attendant at the Society's various meetings. His great experience of commercial matters made him a very valuable member when the Council acted as the Royal Commission for the Chicago Exhibition in 1893. Dr. Francis Elgar had been a member of the Council from 1891, with an interval of two years, to 1909. Though his chief interests were concerned with the Institution of Naval Architects, t which he devoted much of his time and t which he bequeathed a large portion of hi money, he was an active and very valuabl member of the Society's Council. Sir Owe Tudor Burne had acted on the Council i every possible capacity, as an ordinar member, vice-president, treasurer and chair man, from 1887, with only the necessar intermissions, to the date of his death i February last. Though it was in the work c the Indian Section that he took the greates interest, he yet devoted himself zealously an with hearty goodwill at all times to any othe department of the Society's labours in whic he could be of service.

Besides those who actually died while o the Council, there are several other decease members who had at one time or other serve upon it. These are Sir Edward Birkbec Sir George Livesey, and the Hon. Dudle Fortescue, though it is many years since th last-named served on the Council, as he di at the great age of 89.

Sir Thomas Wardle read several valuab papers on silk manufacture. Mr. Bennett Brough gave the Society three courses Cantor lectures, and one course of Juveni lectures, all on subjects connected with minin He also read several valuable papers on mini subjects, for one of which he received t Society's silver medal. Mr. G. F. Deac long eminent as an authority on question water-supply, received a medal in 1882 for h paper on water waste and constant supply; also took an active part on various occasio in the Society's discussions. Sir Donald Cu was awarded the Fothergill gold medal of t Society in 1880 for improvements in passeng steamers, having for their object the preve tion of loss of life at sea. General Rund read two papers at the Society's ordin meetings, and one at the Canal Confer held in 1888. Sir George Barclay Bruce, t eminent engineer, took the chair at one of t meetings of the Indian Section in 1889.

* See p. 671.

Lord Blythswood, the Earl of Rosse, Lord Amherst of Hackney, and Earl Egerton were all members of the Society of long standing. Amongst other members of the Society who died during the past year should be mentioned Sir Thomas Brooke, Sir Edward Law, Mr. Henry Chapman, a well-known engineer, Mr. Andrew Pears, the head of the well-known firm of soap manufacturers, and Mr. Caesar Czarnikow. Notices of these, and of other members whom the Society has lost during the past year, will be found in the columns of the *Journal*.

XXX.—Finance.

The annual statement of receipts and expenditure was published—in accordance with the usual practice—in the *Journal* last week. It shows the revenue and expenditure for the financial year ending May 31st last, the Assets and Liabilities of the Society, its Investments and the Trusts standing in its name.

During the year the Council received an intimation from the executors of the late Mr. Robert Hannah, who was a member of the Society from 1864 to 1906, and died on April 5th, 1909, that he had bequeathed to the Society a sum of £100.

The Chairman (Sir William H. White), in moving the adoption of the Report, said that there was one point in it which struck him whilst it was being read. It was the practical constancy of the number of members during the past forty years, which seemed to him most remarkable. During that period there had been an enormous increase of population in the regions covered by the Society's operations, and while it was quite true that a large number of other societies, developed on parallel lines, had come into existence, he thought the Society ought to claim a much larger membership than it at present possessed, and that a larger revenue was necessary, if the Society was to do all the work it might do. He hoped the members would use every endeavour to attain this end. A promising opening for enlarged usefulness by amalgamation with the London Institution could not for the moment be taken advantage of, and whether such a union would take place in the future, it was impossible to say, but he felt sure that an increased membership, and an extension of the revenues of the Society, would be followed by very considerable results.

Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., seconded the adoption of the Report. He also wished to endorse the advice that Sir William White had given with regard to their membership. The regular expenses of the Society were becoming more and more every year, and he thought they should use every endeavour to make the Society better known. He was confident that members got their money's worth, and a good deal more, for there was an immense amount of information and literature to be found in the columns of the *Journal*, so that it was well worth subscribing for it alone, even if one was unable to be present at the meetings of the Society. He considered the papers and lectures delivered during the past session had been most admirable; they were full of information and instruction. He hoped the members would put their shoulders to the wheel, and do their best to increase the membership of the Society.

The adoption of the Report was then agreed to.

The Chairman moved a cordial vote of thanks to the Secretary and the other officers of the Society. Mr. Wheatley's retirement had been mentioned: he was sure all those who had the pleasure of knowing Mr. Wheatley, and his literary work, would realise the loss his retirement meant to the Society. They could, however, look back with every satisfaction at the manner in which his retirement had been dealt with, and he felt sure he was expressing the feeling of the members in conveying to Mr. Wheatley their very great regard for him and desire for his future happiness. He thought that in Mr. Menzies they had a successor to whom they could look for great help in the future. He had not come to them unproved for he had done exceedingly good work in connection with the University of London, and also as a literary man, and he hoped Mr. Menzies would be with them for many years to come.

Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., in seconding the resolution, referred to the membership of the Society. He said it was to be remembered that the membership of the Society was not recruited, like many of the professional societies, from comparatively young men. Those who joined the Society were principally of middle-age, whilst a number joined after retirement from lengthened service in India and the Colonies, and consequently the mortality of the Society was much greater than in other cases. The Society, in his opinion, was one of the most living societies in the history of London, and it was not possible for the work to be carried on with greater industry and ability. At the same time, it view of the urgent necessity for providing additional accommodation for the Society, it was most desirable that there should be a steady increase in the number of members. As a former Chairman of the Indian Section, he would also like to mention the deep sense of obligation which he, as well as his predecessors and successors in that office, have always felt to Mr. Digby for the great earnestness he has shown in his work as Secretary of the Indian Section.

The SECRETARY, in returning thanks for this expression of confidence in himself and in the other officers of the Society, referred to the personal loss he had suffered from the retirement of Mr. Wheatley, who had worked under and with him in loyalty and friendship for over thirty years. He felt sure the members would be glad to know that Mr. Wheatley was quite happy in his retirement, as he was able to devote more of his time to his literary pursuits. They had found an admirable successor in Mr. Menzies, who was thoroughly capable of doing all the work which was likely to be put into his hands.

The ballot having remained open for one hour, and the Scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.

PRESIDENT.

H.R.H. The Prince of Wales, K.G.

VICE-PRESIDENTS.

H.R.H. The Duke of Connaught and Strathearn, K.G.
The Duke of Abercorn, K.G., C.B.
Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S.
The Lord Chief Justice, G.C.M.G., F.R.S.
Sir Steuart Colvin Bayley, K.C.S.I., C.I.E.
Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Lord Blyth.
Sir William Bousfield, M.A., LL.D.
The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.
Sir Henry Hardinge Cunynghame, K.C.B.
The Hon. Sir Charles W. Fremantle, K.C.B.
Colonel H. C. L. Holden, R.A., F.R.S.
Lord Curzon of Kedleston, G.C.S.I., G.C.I.E.
Sir William Thomas Lewis, Bart.
The Hon. Richard Clere Parsons, M.A.
Sir Westby B. Perceval, K.C.M.G.
Sir William Henry Preece, K.C.B., F.R.S.
Sir Boverton Redwood, D.Sc., F.R.S.E.
The Earl of Rosebery, K.G., K.T.
Carmichael Thomas.
Sir Aston Webb, C.B., R.A.
Sir William White, K.C.B., LL.D., D.Sc., F.R.S.
Sir John Wolfe-Barry, K.C.B., F.R.S.

ORDINARY MEMBERS OF COUNCIL.

Thomas Jewell Bennett, C.I.E.
Henry Taylor Bovey, M.A., LL.D., F.R.S.
William Charles Knight Clowes, M.A.
William Henry Davison, M.A.
Lewis Foreman Day.
Sir Robert Abbott Hadfield.
Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
Sir John Cameron Lamb, C.B., C.M.G.
Sir William Lee-Warner, K.C.S.I.
Colonel Sir Colin Campbell Scott Moncrieff, K.C.S.I., K.C.M.G.
Colonel Sir Richard Carnac Temple, Bt., C.I.E.
Sir William Hood Treacher, K.C.M.G.

TREASURERS.

Sir Owen Roberts, M.A., D.C.L., F.S.A.
Prof. John Millar Thomson, LL.D., F.R.S.

SECRETARY.

Sir Henry Trueman Wood, M.A.

On the motion of the CHAIRMAN, a vote of thanks to the Scrutineers was carried unanimously.

Sir BOVERTON REDWOOD, D.Sc., F.R.S.E., proposed a hearty vote of thanks to Sir William White for the able way in which he had conducted the affairs of the Society, as Chairman of the Council during the past year. So long as the Royal Society of Arts was able to secure for its Chairmen of Council such men as Sir William, the Society would still continue on its prosperous career.

The motion was seconded by Mr. ROBERT KAYE GRAY, who said he was sure he was only expressing the feelings of the other members of the Council in stating that Sir William White had proved an excellent Chairman, and that the meetings of the Council of the Society were a pattern for other societies.

The motion having been carried unanimously,

The CHAIRMAN acknowledged the vote of thanks.

The meeting then adjourned.

TRADE AND TRAFFIC BETWEEN CHINA AND INDIA.

A remarkably interesting account of Western China, more especially in respect of the opportunities it offers for the opening up of communications with Burma and India, is furnished in the recent Consular Report from Teng Yueh (or Momein as it is called by the Shan tribes) for the year 1908. The province of Yunnan, in the extreme south-west of which Teng Yueh is situated, is of vast extent, the northern districts being fed and tapped by the River Yangtze, and the eastern looking to the railway and waterways of the south to keep them in touch with French Indo-China and Canton, while the west is dependent on Burma for both its import and export markets. Although Teng Yueh has been a treaty port since 1902, there is no navigable river within

nine days' journey, and its trade is dependent on four mule roads, all leading up from Burma across difficult and mountainous country. Western Yunnan has been thus driven to become self-supporting to a large extent. Rice and vegetables are produced in abundance, with the result that there is a large and prosperous population with substantial and comfortable homes and lacking little but the cotton required for the blue clothing seen everywhere among Shans as well as Chinese. This for years past has been brought on mule back from Burma, and the construction of a good road has proved that the traffic finds favour with the people.

Among the products of the country are rice and opium, and of the former more is produced than is required for the food of the people; were it not for the prohibition of the export of rice there would be a good export. Similarly, opium was forbidden to cross the frontier into Burma, but there was a steady demand for the product in Chinese markets. From July, 1908, however, there was a rigid prohibition of the cultivation of the poppy, followed by uprooting of the plants in most places. Where crops, yielding from 300 to 400 per cent. profit, were formerly raised, farmers are now anxiously inquiring what substitute can be grown, profitable enough to enable them to buy imports from abroad. On the whole, the natives are a peaceful and well-disposed class and well aware that improved means of transport and the removal of the prohibition against rice export would be probably the best solution of the difficulty. There are also evidences of mineral deposits, and orpiment is exported in considerable quantities; but, owing to the difficulty of transport, the heavier minerals have only been worked in small quantities required for local consumption. Iron cooking pans and agricultural implements find their way to a certain extent from Upper Burma, but the price is too prohibitive for the trade thereon to develop.

As for the trade during the year, the silver return was the best that has been reached, but on a gold basis it became an actual decrease, owing to low exchange, the total being £235,449 as compared with £281,484 in the preceding year.

There is a good sale for such light and strong articles as can stand the overland journey, viz., towels, enamelled ware, cotton, thread, ribbons, umbrellas, metal buckets, tinned milk, cube sugar, carpenter tools, needles, and matches. Quite poor towns in China, if only possessed of good communications, are ready consumers of glass and kerosene oil, but the former is unknown in Teng Yueh.

Among the exports, raw yellow silk, hides, and musk figured prominently, the last item being evidently one of some commercial importance, for a traveller for a French perfumery firm is now engaged on his third musk-collecting expedition. Ponies and cattle of a sturdy breed are raised on these mountain pastures, and these should presumably find a ready market in Burma. Judging from the climatic conditions—which include a rainfall of about 60 inches, most of this falling in nine months of the year, and a long-day winter with warm bright days and a light frost at night, the thermometer ranging from 29° to 89° F.—the writer of the Report under review anticipates that apples, pears, apricots, plums, cherries would flourish, and given better communications, would prove a valuable addition to the exports. It is calculated that of the total trade entering Teng Yueh, about 70 per cent. proceeded inland, three-fourths of this quantity being probably consumed in Tali-fu and Yunnan-fu, one-fifth being transported across the upper Yang-tze and Sz-chuen, and the remainder finding its way into Kwei-chow. The fact of this trade making its way over mountain tracks for journeys of over two months shows that physical obstructions are no real hindrance to goods in popular demand. With the hope of establishing a good market for cigarettes, the British-American Tobacco Company have sent two travellers with gramophones and samples of cigarettes for free distribution among the Chinese, who seem quite willing to become regular customers for the goods, which clearly give satisfaction.

The Tonkin-Yunnan Railway was expected to reach Meng-tse this spring, and will be rapidly pushed forward to Yunnan-fu, the provincial capital, the completion of the line being promised early in 1910. The French rail-head will thus be brought within 220 miles of Tali-fu, the great distributing mart of Western China, while the British rail-head at Bhamo will be 280 miles from the same goal, the 60 miles difference meaning four days' heavy marching for a caravan on the Yunnanese roads. And during the malarial months the Burma route is most prejudicial to the mule drivers, which is a further handicapping of the British route, and shows the urgent need of carrying out the long-desired railway communication between Bhamo and Tali-fu. The same point, it may be remarked, is dwelt on in the Burma Administration Report (which has just reached the India Office), where it is pointed out that an important trade is greatly hampered by the want of easy communication in this direction.

A NEW FIRE EXTINGUISHER.

All who are interested in the question of fire extinction are familiar with the dangers and difficulty inherent to combating conflagrations where petroleum, gasoline, benzine, or other liquids lighter than water, are involved. As is well known, the attempt to extinguish with streams of water in such cases results usually in a spreading of the inflammable liquid, an increase of the area of combustion, and a greater intensity of conflagration. The use of steam or of a current of inert gas is available only for incipient conflagrations in well-closed rooms. It presupposes, also, the permanent location, on the spot, of stationary apparatus for the purpose. Accord-

ing to the American Consul at Chemnitz, a distinct step forward in the means of battling with such conditions has been made in Germany, where the use of a tenacious foam, dissipated with difficulty, has been found of great value in cutting off the supply of air necessary to maintain combustion, and thus extinguishing flame. The method and the requisite apparatus have been perfected at Salzkotten, near Minden, in Prussia, and have been submitted to exhaustive tests by the heads of the fire brigade and others interested in the question of protection against the dangers from combustible liquids. The apparatus employed consists of a simple metal cylinder, provided with a long spout, and divided into two chambers. One chamber is charged with an aqueous solution of potash alum and sodium sulphate, the other with a similar solution of sodium bicarbonate, sodium sulphate, and licorice extract. The cylinder is so arranged that, on being inclined or reversed, the two solutions mingle as they issue from the spout. There is no pressure evolved, and consequently the liquid does not issue with sufficient force to cause a spattering of the burning hydrocarbon upon which it may be poured. The result of the chemical reaction between the alum and the bicarbonate, is a prompt evolution of carbon dioxide which, in contact with the licorice solution, forms na exceedingly stiff and persistent foam. Such a layer of foam, containing an inert gas upon the surface of a burning liquid, cuts off all access of air, and combustion necessarily ceases. The temperature of the liquid may have reached a sufficiently high point, so that through evaporation, bubbles of the vaporised hydrocarbon rise, for a time, through the stratum of foam, and tongues of flame flutter over its surface. These soon cease, for simultaneously with the evolution of the carbon dioxide, there is a loss of latent heat, the temperature of the foam-yielding solution falls, and this, in turn, cools down the combustible liquid. The solution acts thus, in a double manner, as a protective agent. Among the numerous tests to which the apparatus has been submitted by the heads of fire departments in Germany, the following, by the head of the Hanover department, may be mentioned. An iron vessel, five and a-half by two and a-half feet in size, and four inches deep, received a charge of eighteen gallons of benzine. Benzine was likewise poured on the ground where the vessel rested. The liquid in the vessel, and outside the same, was lighted, and allowed to burn for three minutes. The contents of two foam extinguishers were then allowed to flow over the whole. Combustion was promptly arrested. The superincumbent layer of foam was then removed, and the benzine lighted anew. The attempt was now made to extinguish the flames by means of water, first with a simple, portable house extinguisher, and then, with the use of the city water supply, issuing from a two-inch hose. In neither case could the fire be extinguished. On the contrary, the area of combustion was rapidly extended, until it covered over forty square yards. It was then necessary to discontinue the use of the hose, on account of the danger to the buildings surrounding the court in which the experiment was conducted. The success attendant upon this and similar tests has led to the conviction among German authorities on protection against fire, that the foam extinguisher is capable of rendering valuable service in all places where combustible liquids are stored, and especially in automobile garages, and motor yachts. The use of liquid fuel for rapid locomotion by land, water, and air is extending so rapidly, that the new protective, it is said, will meet a distinct need.

FOREIGN SHIPOWNERS AND INSURANCE FUNDS.

It is often urged by British shipowners that they labour under great disadvantages as compared with their foreign competitors in that their obligations to their crews are greater. A return just issued at the instance of Lord Muskerry does not altogether support this contention. Indeed, it shows that in some important respects, and in some countries, more is done for the foreign sailor than hitherto has been done for the British. Take, for example, old-age pensions, and widows' and orphans' pensions. In Austria-Hungary members of the mercantile marine have no legal claim to pension, but there is a charitable fund, under official control, for the relief of old and disabled officers and seamen, and their widows and orphans. In Belgium, owners of merchant vessels are under obligation to pay to the Seamen's Benevolent Fund (Caisse de Secours et de Prévoyance), a sum amounting to 1½ per cent. of the total expended on the wages of all the seamen they employ. All officers, mechanics, sailors, stokers, stewards, cooks, and apprentices sailing under the Belgian flag, and enrolled on the ship's books, with the exception of seamen in Government service, and policemen, have to subscribe to the fund a sum amounting to 3 or 4 per cent. of their wages, according to their rank. Out of this fund pensions amounting to £9 in the case of cabin boys, and running up to £30 in the case of captains, are granted (*a*) in the case of inability to work on acconnt of old age, or on account of an accident met with while in the exercise of their calling; (*b*) in the case of infirmities incurred in the exercise of their calling. Widows of seamen who are members of the benevolent institution receive, under certain specified conditions, a pension varying from £9 to £24, and an addition of £1 16s. 8d. to £3 for every child under 18 years of age. In order that the widow may receive a pension her husband must have contributed to the benevolent fund for 20 years, and have been at sea for 15; their married life must also have lasted for a year. An orphan's pension is the same as that of a widow without children. Should there be more than one orphan in a family a further sum of £1 16s. 8d. to £3 is granted for every additional child.

Danish shipowners have no obligations towards their captains, officers, and crew as regards such pensions, but in France pensions are paid to all seamen on the register who have done 25 years' service in the navy or mercantile marine, and have reached the age of 50, unless previously incapacitated from work by illness. The pension for widows of seamen is fixed at half the maximum pension granted to the husband. After the death of the mother, or if she forfeit in any way the right to the pension, the child or children of the deceased pensioner receive, whatever may be their number, an annual sum equal to the pension that the mother would or might have drawn. The sum of 3 per cent. on the wages of seamen engaged by the month or voyage is paid into the "Caisse des Invalides," and the same percentage is also paid on the wages of seamen employed in the whale and cod fisheries. Owners and managers of all kinds of vessels and trades pay a tax of 3½ per cent. on all wages inserted in the ship's articles. The present subscription from seafaring men, whether on the register or not, engaged in ocean navigation, the international coasting trade, and deep sea fisheries is 1 per cent. on the salaries of officers, and ¾ per cent. on the wages of seamen. And there is a national fund for the benefit of sailors against the risks and accidents incidental to their profession.

In Germany the owner of a merchantman is not, as a rule, personally liable for compensation to seamen in case of accident. This burden is met by compulsory insurance, based on the principle of mutuality. The law as to it rests on three main principles: (1) that all persons employed at sea must be compensated for accidents occurring in the course of their carrying on their work; (2) that the necessary funds for this compensation must be provided by the shipowners alone; and (3) that this compensation must be provided by the shipowners to the extent of their trade. As with accident insurance, so is the provision to be made for old age taken out of the hands of the single employer, for the single case, and is regulated by general public legal rules, and here the liabilities of the shipowner are the same as those of every other employer. The "Invaliden Versicherungsgesetz" of 1899 includes, in the same degree, the ships' crews of all German merchantmen, without distinction as to their size or purpose. It embraces also foreign seamen, though they can, by a decision of the Federal Council, be excluded from the insurance. But in that case the employer is bound to provide the share which would otherwise fall to them. Widows and orphans of seamen enjoy certain advantages from the accident insurance funds, but further than this there does not exist in Germany at the present time any liability on the part of shipowners to provide for the widows and orphans of seamen employed by them. A Bill has, however, been introduced to provide for them, and is likely to become law.

In Italy shipowners are responsible for the deductions from the wages of their crews which are due to the "Fund for the Incapacitated of the Mercantile Marine," whose objects are: (1) to provide pensions and assistance to incapacitated seamen inscribed in the registers of seafaring men who have contributed to the fund; (2) to give assistance to seamen navigating under the national flag who may be destitute, or suffering from serious and unforeseen misfortunes. The contributions from seamen's wages to this fund vary from 4s. per month for a master mariner of a foreign going vessel to 8d. for a cabin boy. Assistance is given to widows without, or according to number of, children by the Fund. In the Netherlands, no provision is made for old-age pensions, or pensions to widows, and the same remark applies to Norway, Russia, Spain, and Japan. In Sweden, the Royal Regulations for Seamen's Homes provide for pensions to be paid by the seamen's homes to sailors either injured or in permanent ill-health, or too old to work, in proportion to their circumstances, and the same Regulations which provided for the husband or father, provide for the support of widows and orphans by the Seamen's Homes. There is also accident compensation.

THE SOCIETY OF ARTS AND AFFORESTATION.

One of the first objects to which the Society of Arts devoted its attention, was the encouragement of tree-planting, and as this fact is constantly referred to in discussions about afforestation, it may be interesting to give a few figures as to what was actually done. In 1758—four years after its establishment—the Society, in view of the fact that "a continual supply of useful timber is absolutely necessary, as well for the ornament and conveniency, as for the security of these kingdoms," offered a number of premiums, generally in the form of gold or silver medals, for the planting of various kinds of trees. These premiums were continued from year to year till 1835, and in this period no fewer than 115 gold and 34 silver medals, in addition to a few pecuniary premiums, amounting to some £200, were awarded. It is impossible to state with exactitude the number of trees planted which these awards represent, for although, in some cases, the particulars are given in the records of the Society with extraordinary precision, in others, such phrases as "extensive plantations" are used; but at the very lowest estimate this number must have considerably exceeded 50 million, of which some 20 million were firs and larches, and some 15 million oaks.

DEW-PONDS.

In Mr. George Hubbard's paper on "Dew-ponds," read before the Society on March 3rd (see *Journal* of March 5th, 1909, p. 335), it is stated "that at Gibraltar a large portion of the rock has been covered with corrugated iron on a wooden backing. On this surface the warm moisture-laden wind becomes chilled,

and the dew is deposited, and if I am rightly informed Gibraltar has now a supply of pure water."

Full details of the water system of Gibraltar may be found in the "Gibraltar Directory," pp. 7 and 8 of the section "Historical Notes," from which it appears that the supply of water for dietetic purposes depends entirely upon the rain-water collected on specially prepared areas, supplemented when necessary by distilled sea-water.

"In the year 1903," says the *Directory*, "an additional area was prepared as a collecting ground for rain-water on the sand slope over Catalan Bay, on the east side of the Rock. Ten acres of the sand were covered by galvanised corrugated iron sheets, with a channel at the bottom, from which a tunnel 700 yards in length was constructed; through the tunnel the water flows by gravitation in four reservoirs."

This work of laying down the "galvanised corrugated iron sheets on creosoted fir framing," was designed and executed by Mr. Wallace Copland, Engineer to the Gibraltar Sanitary Commissioners, and appears to have been carried out not for any purpose in connection with the formation of "dew-ponds," but merely as a means of collecting the rain.

ARTS AND CRAFTS.

New Lustre Pottery.—There have been so many new developments in artistic pottery, both at home and abroad in recent years, and so large a number of these have been connected with chemical experiments in various glazes, that one hardly looked for anything fresh, especially in the direction of flambé and lustre. Ever since the last Paris Exhibition (and for some little time before it) experiments have been made all over Europe in the direction of crystalline glazes, and within comparatively recent years at home we have seen both the wonderful re-discovery, as it might almost be called, of painted lustre first attempted by Mr. de Morgan, and brought to such perfection by Mr. Burton, of the Pilkington Tile and Pottery Company, and also Mr. Bernard Moore's admirable flambé. During the last few weeks, however, Mr. Goddard, of Messrs. Ashworth and Co., has been showing in London some results of his experiments in Staffordshire lustre. Mr. Goddard, so far at any rate, has not attempted anything in the way of painted lustre, but has contented himself with obtaining lustrous effects in his glazes—and many of his results make not only gorgeous lustre but beautiful colour—two things which do not always go together. It is apparently copper lustre with which Mr. Goddard works exclusively; at any rate none of the pots shown suggested at first sight silver lustre. Perhaps one of his most striking productions is the practically black glaze which in the light glitters with all the colours of a very brilliant rainbow. This he has often displayed on eight-sided bowls, where the various angles at which the sections are seen makes them all take different colours. He showed also a number of small vases in rather neutral coloured glazes, very unusual in lustred ware, and some of them were extremely delicate in effect. Amongst the most interesting pieces, however, are those in which the copper oxide has developed, as it were accidentally, into both turquoise blue and a deep ruby red, the contrast subtly harmonised by the sheen of lustre over it all. But, perhaps, the most delicate combination of colours occurred in a vase quite like a peach in effect, a peach which has ripened on one side only. It varies from a deep blush pink on the one hand to a pale greenish yellow on the other. Some of the delicate colourings where pale tints are flecked with little spots of pink are also very successful. The more startling colour schemes, where a vase varies from orange to deep melon green, or to a fine dark blue, have not the sublety of the more delicate effects, and would, perhaps, pall upon one after a time, though they are quite interesting to see.

Mr. Goddard has succeeded not only in producing lustre ware, but in getting a number of new and beautiful combinations of colour. There is, of course always an element of chance in this kind of thing (the fire may treat one piece kindly and practically spoil another) but the pots he exhibited went to show that he had a very adequate control over his material—that he had not only worked with a wide range of colours but knew pretty well how his ware was coming out of the kiln.

Arts and Crafts at Shepherd's Bush.—Huge exhibitions, though they very often contain a good deal of interesting work, are not generally easy places in which to find objects of decorative interest; and this year's show at the White City is no exception to the rule. From the plan, one would suppose that nothing would be easier than to inspect the Palace of Decorative Art and the Palace of Applied Arts and Crafts and to find at once all that was to be seen in the way of art and workmanship; but this is not by any means the case. The Palace of Decorative Arts, apart from a show of statuary, a large and good collection of photographs, and a few pictures, contains, it is true, a quantity of furniture exhibited by firms of repute, but this is almost all of it old, or on old lines—practically a retrospective exhibition rather than a show of the current workmanship of to-day—while the Palace of Applied Arts and Crafts (the stands are not yet all completed, and it is, therefore, perhaps, hardly fair to judge of its contents) seems to be mainly given over to manufactured jewellery. Indeed by far the biggest collection of craft work is to be found in the Women's Palace—though even here one is sometimes puzzled to find the connection between the exhibits and the title of the building in which they are collected. The International portion of the exhibition is, as such things usually are, a sort of mixture of a British bazaar and a street in a continental town; but there is enough in it to throw some side lights on what is being done in a few places abroad. The Dutch metalwor

and pottery—more especially the Arnheim ware—remind us (if we need reminding after the exhibition last year) that in Holland the *Art Nouveau* which we think of here already as ancient history, is by no means dead; whilst the Florentine leatherwork shows how the practice of lacquering leather has regained ground in the last few years—and how much more satisfactory is the colour of the Italian work than that of the corresponding English production.

The most important pieces of decorative work shown in the Palace of Decorative Arts, apart from the sculpture, much of which is, of course, in a sense decorative, are the two enamelled plaques and the large peacock candelabrum carried out in copper and enamel, exhibited by Mr. Alexander Fisher. Of the carpets, the beautiful examples shown by Messrs. Cardinal and Harford are, of course, all Oriental and the finest specimens are old. Messrs. Treloar's exhibit is interesting as including not only a number of Eastern carpets obviously made to European order, but also some very fine Axminsters. It is interesting, too, to see almost side by side, a remarkably satisfactory Axminster rendering of a beautiful sixteenth century Persian carpet from South Kensington and a rug bearing the Royal Arms made in the East. One smallish room is devoted to furnishing silks. They are mostly after old patterns, but those few that are modern are very much up-to-date. Some of the purples and mauves and kindred shades are very fine.

One is rather at a loss to understand why Mr. Howson Taylor's pottery should be shown in the Women's Palace except that it was there last year;—and there it is again—together with a few other exhibits which do not seem to have any special relation to women's work. Amongst the general exhibits most worthy of notice are the bookbindings of Miss Gedye and the jewellery of Miss F. Rimmington. This last, though on lines not altogether different from what other people are doing, is sufficiently unlike other work to be distinctively the artist's own—and is, moreover, good both in design and workmanship. It is only natural, however, that the greater part of the arts and crafts exhibits in the women's section should be connected with needlework, and there is quite a varied show of lace, embroidery, and such like; but it is, for the most part, rather the output of village industries than the production of very technically skilled workwomen.

From Narbett, Pembrokeshire, comes a case of quilted dressing-gowns, dressing-jackets, bedspreads, and other objects which reveal the fact that quilting is after all a British industry, and that those who admire the quilts to be seen in Sicily and elsewhere abroad, could with a little trouble get quilted things in this country quite as interesting in their way. English quilting in the old days was mainly, it is true, white stitched with white, and though the show at Shepherd's Bush is for the most part in colours, the stitching is of the same tint as the ground; but there is no reason why use should not be made of contrast in colour between the ground and the stitched pattern upon it.

There is lace from Ireland and elsewhere, but the most interesting show of this kind is that from Kingston Bagpuize and Longworth (Berkshire), where old Italian and other designs are reproduced by the villagers in gold, silver, or aluminium as the case may be. Some of the patterns are very satisfactory, and care is taken to get and to utilise different shades of gold and silver. Embroidery and drawn thread work are shown from places as distant as Hungary and India as well as from those much nearer home. There is a smallish frame of work from Dunleckney, County Carlow, Ireland, which includes a few pieces which, both in colouring and design, are at first sight, curiously Oriental. On closer inspection they remind one to some extent of a certain kind of work done in Brittany—itself reminiscent of Oriental needlework.

Although there is not as much modern craft work to be seen at the White City as the descriptions of the "Palaces" might lead one to expect, there is nevertheless scattered over the exhibition a sufficient quantity of such work to prove interesting to those who care for such things—only they must not mind the trouble of looking for them amongst a varied collection of other objects.

NOTES ON BOOKS.

PRIVATE HOUSE ELECTRIC LIGHTING. By Frederic H. Taylor. Third Edition. London: Marshall and Co.

This little manual will be found to give just the amount of information required by anybody using the electric light or contemplating its installation. Systems of wiring are described; the ordinary appliances, switches, lamps, fuses, and fittings generally are all figured and described; the cost of an installation and its working is discussed, and there is a fina chapter upon generators.

SPECIAL HOSPITALS. By Richard Kershaw. London: George Pulman and Sons, Ltd.

To those who claim specialism as the monopoly of modern times the historical chapter which opens this little work should prove enlightening. "Specialism in medicine," says Mr. Kershaw, "was nowhere more developed than in the ancient universities of Egypt, of Greece, and of Rome. In Egypt the sacerdotal doctors divided the human body into 36 anatomical parts, each part being dedicated to its own special deity;" and he quotes Herodotus to show that "every corner is full of physicians, some for the eyes, others for the head, many for the teeth, and not a few for the stomach and belly." According to Georg Ebers, "whoever required a physician sent for him, not to his own house, but to a temple.

There a statement was required of the complaint from which the sick person was suffering, and it was left to the principal of the medical staff of the sanctuary to select that master of the healing art whose special knowledge appeared to him to be suited for the treatment of the case." It is possible, of course, that the medical and surgical methods of ancient Egypt might appear somewhat crude to the modern practitioner, but the gold filling which has been found in the teeth of mummies shows that in dentistry, at least, no little progress had been made even in the time of the Pharaohs.

A great many centuries had to pass before this country could vie with the ancient world in the matter of medical specialism. In the sixteenth century so little progress had been made here in medicine that "it was held in both St. Andrews and Glasgow Universities to be a section of the theological faculty, until at the University of Aberdeen the first professor of medicine, and the only teacher of medicine then in Britain, was appointed, and paid at the rate of 'ten merks yearly.'"

The nineteenth century, however, witnessed a sudden and great development of special hospitals in this country. In 1801 the London Fever Hospital was founded, and in 1804 the Royal Ophthalmic Hospital. In the following year the citizens of Glasgow built a Lock Hospital, while in 1806 an Eye Hospital was opened in Exeter. Thenceforward the growth of special hospitals continued in ever-increasing numbers, until at the close of the century the United Kingdom boasted some 170 institutions for all kinds of diseases. The illustrations which Mr. Kershaw has chosen for his book are not without interest. One of the first represents the temple at Epidaurus, where a patient is sacrificing while his injured leg is being licked by the sacred servant. The last is a photograph of the operating theatre of the London Throat and Ear Hospital, fitted with all the appliances of the most modern science.

GENERAL NOTES.

BRUSSELS EXHIBITION.—The Royal Commission for the Brussels Exhibition have issued a memorandum containing information for exhibitors, from which it appears that the space to be occupied by the British Section is a little over 200,000 square feet. There will be a charge for space, varying from 2s. 6d. to 6s. per square foot. The higher charge includes cost of show-cases, the handling of goods in transit from the railway to the exhibition space, storage of empty cases, and re-loading at the close of the exhibition. The installation of machinery is not included. The Commission will pay half the charges for motive power supplied to machinery to illustrate processes of manufacture. A uniform scheme of decoration will be adopted, and various additional facilities will be provided for exhibitors and their agents. The Belgian State Railways charge full rates on the outward journey, but undertake to return exhibits free. The British railway companies make a reduction of 50 per cent. on returned exhibits—presumably the full charges will have to be paid for the outward journey.

TOWN PLANNING AND HOUSING EXHIBITION.—A Town Planning and Housing Exhibition will be held at Hampstead Garden Suburb, from July 14th to August 7th. A number of cottages and houses in the Garden Suburb will be open for inspection, and a large collection of plans, models, &c., will be on view in the Institute During the Exhibition, lectures and conferences will be held. Admission will be free on presentation of visiting card.

BEE DISEASE.—The Board of Agriculture and Fisheries desire to warn all bee-keepers that an outbreak of disease, believed to be identical with the Isle of Wight bee disease, has occurred in several hives in Buckinghamshire. This disease, which has destroyed almost all the bees in the island from which it takes its name, is due to a bacillus closely resembling the bacillus of Plague, and no remedy for it is known. It is of the utmost importance, therefore, that bee-keepers should take every precaution to prevent the disease spreading, and they are strongly advised to keep a careful watch for any signs of its appearance. A full description of the disease was published in the *Journal of the Board of Agriculture* for February, 1909, and bee-keepers who find symptoms of disease corresponding to the description there given should communicate with the Board of Agriculture and Fisheries, 4, Whitehall-place, London, S.W.

EMPLOYMENT OF CHILDREN.—Attached to the annual report of the Chief Inspector of Factories and Workshops is a report by Miss Squire, one of the lady inspectors, on the employment of children and young persons. An enquiry was made by Miss Squire into the main features of the employment of children in carding of hooks, eyes, and buttons in Birmingham. The investigation showed that children of from 7 to 13 years of age are employed to a very considerable extent, often at late hours by artificial and insufficient light, straining to the eyes, in this monotonous and tiring work in their own homes; that the work is largely dependent on child labour, and is miserably paid, being a last resource of poverty where there are children to help. The employment cannot at present be regulated as it is excluded from the scope of the Factory Act by Section 114, and from the Children's Employment Act, the parent being the employer. Sometimes the work was found to be supplementary to Poor-law relief. Further inquiry seems to be needed.

Journal of the Royal Society of Arts.

All communications for the Society should be addressed to the Secretary, John street, Adelphi, W.C.

NOTICES.

THE ALBERT MEDAL OF THE SOCIETY.

The Council of the Royal Society of Arts attended at Marlborough House on Wednesday, the 7th inst., when His Royal Highness the Prince of Wales, President of the Society, presented its Albert Medal to Sir Andrew Noble, Bart., K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

The members of the Council present were:—Sir William H. White, K.C.B., LL.D., D.Sc., F.R.S. (Chairman), Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Thomas Jewell Bennett, C.I.E., Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., Lord Blyth, Sir William Bousfield, M.A., LL.D., Henry Taylor Bovey, M.A., LL.D., F.R.S., William Henry Davison, M.A., The Hon. Sir Charles W. Fremantle, K.C.B., Sir John Cameron Lamb, C.B., C.M.G., Sir William Lee-Warner, K.C.S.I., Sir Westby Perceval, K.C.M.G., Sir William Henry Preece, K.C.B., F.R.S., Carmichael Thomas, Prof. John Millar Thomson, LL.D., F.R.S., Sir William Hood Treacher, K.C.M.G., and Sir John Wolfe-Barry, K.C.B., F.R.S.

PRACTICAL EXAMINATIONS IN MUSIC.

The practical examinations in Music were not concluded this year until the 3rd July, too late for the results to be included in the Report of the Council. They lasted for 10 days.

The examinations were conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 400 candidates entered, and of these 392 were examined, a decrease of 40 as compared with last year. There were 298 passes and 94 failures.

The following were the subjects taken up:—Piano, singing, violin, violoncello, clarinet, and flute. 323 entered for the piano, 247 of whom passed; 51 entered for the violin, of whom 36 passed; 3 entered and passed for the violoncello; 13 entered for singing, of whom 10 passed; 1 entered and passed for the clarinet, and 1 for the flute. One medal was awarded.

The Examiners mention the following points, as some to which candidates and their teachers might, with advantage, pay special attention. The sight-reading, especially of the singers and pianists, was, on the whole, inferior; the tone-quality of the pianists (more especially in the junior grades, but to some extent in all) was often susceptible of decided improvement, and more thought might well be applied to the inculcation of the technical methods necessary to secure tone-quality; among the pianists, pedalling was often a weak feature, and among the violinists the bowing was often stiff. In many cases, candidates entered for a standard for which their attainments were, as yet, hardly sufficient; but, on the other hand, a considerable number gave evidence of talent and good training.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE PUBLIC SUPPLY OF ELECTRIC POWER.*

By G. L. Addenbrooke, M.I.E.E.

PART I.

Connection with Lighting.

When about twelve years ago the question of the distribution of electric power first seriously arose in this country, it was thought that it would be necessary to separate it from the supply of electric light, except where the power users were small, on account of the difference in pressure caused by throwing large motors on and off the supply mains. These differences were important at the time, and in the egislation relating to power supply, supplies for power and lighting were largely differentiated. Since then, however, improvements in prime movers, particularly the adoption of the steam turbine, distribution at higher pressures, and the better design of motors and of appliances for starting them, have brought it about that in properly designed systems of sufficient size the pressure in the mains can be kept within such limits that good lighting is practicable from the same mains which supply power.

An electric power station of modern type is, therefore, capable of supplying electric energy for all purposes, including heating, and to avoid unnecessary capital expenditure and duplication of supplies it is advantageous that the different classes of services should be supplied from the same source.

I mention this at the outset because electric lighting legislation in the United Kingdom has been a barrier to electric supply on a wider basis, and still remains so, and because my subject is already too extensive to permit me to refer to lighting supply at any length.

Preliminary.

I wish also to commence by asking the indulgence of my hearers for the method of treatment which I have adopted on the subject of these lectures.

To be successful the supply of electric power or energy must rest on an economic basis; there are other points which tell considerably in its favour and which are not capable of being expressed in figures, but speaking generally cost is a governing factor.

It is impossible, therefore, to avoid making this a considerable feature in any comprehensive presentation of the subject, and the importance of the technical points which arise is approximately measured by the way they bear on it. Although, therefore, the technical side is to myself and probably to my audience, the more interesting, I have felt compelled to discuss the economic sides of the question at considerable length. The bearing of the technical points will then, I think, be better understood and the possibilities of development be more correctly estimated.

Uses of Electrical Power.

As the adoption of the electric motor for driving machinery is now becoming so universal not only in manufactories, but in the mining and other industries, and electric power supply is making progress for railway working besides in its application to tramways, lighting, and heating, it will be worth spending a little time to commence with, in trying to form some conception of the extent to which power is at present used in this country, and the proportion of it which has already been electrified.

Coal Commission Report.

There are, unfortunately, no direct statistics of this as yet, though I hope such will be obtainable when the report of the industrial census which is now being taken is forthcoming. Some estimates were, however, made at the time when the late Coal Supply Commission were sitting, and these, coupled with experience gained in connection with electric power supply, enable a few figures to be put forward which are at any rate of the right order though they may not be very accurate.

According to the Coal Supply Commission report, there were used in 1903 about

53,000,000	tons	of coal in	factories.
18,000,000	,,	,,	mines.
13,000,000	,,	,,	railways.
5,000,000	,,	,,	brick and chemical works.
28,000,000	,,	,,	iron and steel works.
15,000,000	,,	,,	gas works.
32,000,000	,,	,,	domestic purposes.

And probably these figures are not far from correct now.

* The Course consisted of three lectures, delivered on January 18 and 25, and February 1. In re-arranging the material for publication, the lecturer has preferred to divide it into four parts.

Horse-Power in United Kingdom.

Of course, a great deal of coal is used for heating, but, taking this into consideration, it would appear, from the above and other data, that the total horse-power installed in the United Kingdom in factories and mines is something under 9,000,000 horse-power, including gas-engines, and there is also about 1,300,000 horse-power installed in electric lighting, power, and tramway stations.

To estimate the amount of power used on railways is not easy owing to the difficulty of defining what is the horse-power of a locomotive; but it would appear that if the railways of the United Kingdom were all driven electrically with power supplied from large generating stations, the horse-power required would be well under 2,000,000. As an interesting side issue, it may be worth noting that there must also be much over 500,000 horse-power installed in motor-cars and motor omnibuses in this country at the present time, and that this total is certain to be greatly increased in the near future.

These figures must be taken as very approximate, but in the absence of more definite information they are useful in giving some idea of the magnitude of the problems involved. It is also interesting to have some data showing the amount of power by which the population of this country has supplemented its own efforts to reach our existing state of civilisation. It will be noted that this is in the neighbourhood of ¼ horse-power for each person for all purposes. The writer considers that this is rather an over than an under estimate, as he invariably finds that power users have a tendency to exaggerate the amount of power they use and to under estimate the amount of coal used per horse-power hour.

In the United States it has been usual for some time to take a power census every five years, and the figures of the last, viz., 1905, are quoted in the *Electrical Review* of October 11th, 1907. Without going into detail it may be said that the figures show a total of nearly 15,000,000 horse-power in use, including water-power, the figures for electric supply being for the same date about three times those for this country. The United States population is of course double that of Great Britain, but nevertheless these figures are worthy of the consideration of politicians, as it is evident that no unnecessary obstacles should be placed in the way of power supply, if this country is to maintain the place it now holds. It is also worthy of note that between 1900 and 1905 the horse-power installed in the United States is stated to have increased 40 per cent.

To return, however, to our subject. Out of the 8,000,000 to 9,000,000 horse-power employed in the mines and manufactures of this country, probably 70 per cent. is situated within populous districts, since over 78 per cent. of the population live in such districts, and manufactures, mining and population are always closely associated.

Power Capable of being Supplied from Public Supply.

Of course some of this power is not suitable for conversion to electric driving, and some has already been converted, but we shall probably not be far wrong in saying that there is at this moment in Great Britain over 4,000,000 horse-power of engines situated in towns and urban districts and their neighbourhoods, and within the central portions of the areas of the power supply companies who have been granted acts for this purpose, and which could be economically replaced by power supplied from properly grouped stations, the remainder being in large works and collieries or works situated in the more rural districts which can probably most advantageously produce their own electric supply.

That the possession of cheap power in a form which is easily sub-divided, and utilisable over large areas, would lead to extensions in its use, is also manifest, though it is impossible to define this in figures.

Economies to be Effected in Use of Coal.

To give an idea of the economies to be effected if the best modern practice were generally adopted for generating power, the Coal Commission estimated that if electric driving and the most modern plant were universally substituted in collieries for the plant at present in use, the coal consumption which now is more than 6 per cent. of the total coal raised would be reduced to one-third, and it is safe to say that if electric main winding which is now coming into use, were also adopted, and if the supply were furnished by grouped stations where practicable, even this economy would be exceeded, so that there would be a saving of coal in this

industry alone of some 12,000,000 tons, which at the low value of 5s. per ton, would effect a saving of £3,000,000 per annum.

The saving of coal by adopting electric driving and grouping the power supply as far as possible would not be so great in other industries as in mining, but it is a moderate estimate of what we know the savings to be by grouping or using the most efficient modern isolated plant to say that the coal consumption, taking all other industries, could on an average be reduced to half of what it is now, or by over 20,000,000 tons per annum, of an average value of nearly £10,000,000 if carriage and handling is included. The annual cost of this power at the average figure of £6 per horse-power, including interest and depreciation, is for all industrial purposes in excess of £50,000,000 per annum.

Industrial Districts of United Kingdom.

Most of the power used in the United Kingdom is located in fairly well defined areas, of which Lancashire and Yorkshire are the principal; then follow the North-East Coast, then the Midlands, next the Clyde Valley, and South Wales, and lastly the metropolitan area. There are besides these several other districts of less considerable dimensions.

There being this opening for electrification and for power supply, we have next to consider how the demand is being met. This is now being done in three ways:—

(1) Manufacturers and mine owners are installing their own plant.

(2) Supply is being given from the stations of electric power supply companies, which were established for this purpose.

(3) Supply is being given from the public supply stations established primarily for lighting towns, of which, outside London, the larger proportion is in the hands of the local authorities. There are in all now 451 of these undertakings throughout the country, of which 297 are in the hands of the local authorities and 154 are operated by companies.

As regards heading (1) there will always be a certain number of works and mines situated in isolated positions, which, if they desire electrification, as most of them will sooner or later, must in all probability depend for their supply of energy on generation within their own confines, or they may be able to form a little local group. On the other hand, there are works and mines operated on such a large scale and able to utilise such a large horse-power that they can erect and work their own generating stations to as great an advantage as if they took their supply from an outside source, though it is very remarkable how in a number of instances such works have agreed to take a supply of energy from an outside source where a suitable one has been available. With electric power users in these categories we shall only be incidentally concerned in these lectures, which will be devoted to consideration of the conditions which cover supply from a public source.

I have tried to get some figures which would indicate to what extent electric power has already been privately installed in works in this country, but owing to the multiplicity of manufacturers, and the amount of plant which has been imported from abroad, I have found it impossible to arrive at any data of serious value. Probably 1,000,000 horse-power is an under estimate.

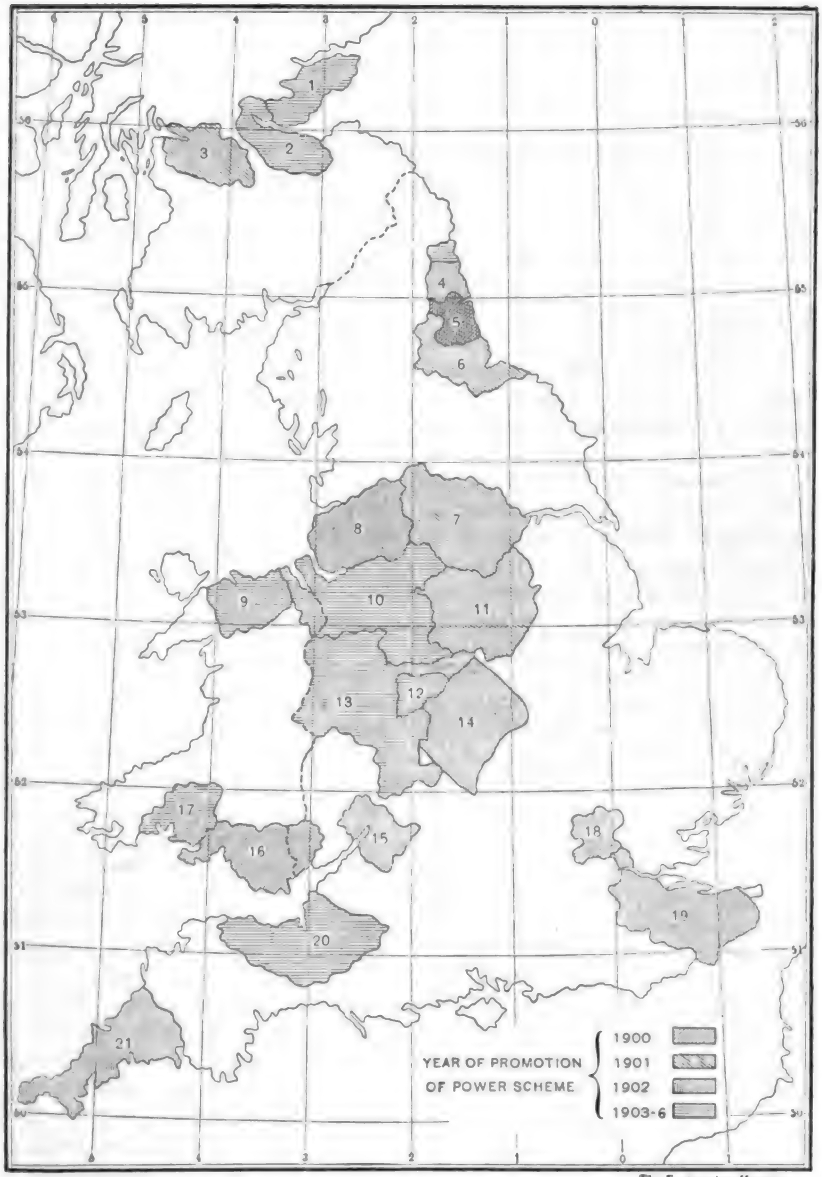
The Electric Power Acts.

It was in 1898, or just over ten years ago, that proposals for supplying power from public centres on a large scale first came to a head in this country. At that time, the question of municipalities supplying power in any way, except to small users who could be served off the lighting mains, had not seriously arisen.

It was thought improbable at the time that the local authorities would care to undertake this work, or that Parliament would sanction their going into a business which needed so much capital, and which was rather concerned with individuals than with the public at large. At the same time, owing to the wording of the Electric Lighting Acts, they had technically the right to do so where supplying lighting, as, when the Electric Lighting Acts was passed, supply for all purposes was included, since it was not then expected that the demand for power could ever be considerable.

Under these circumstances, and on the findings of the Joint Committee of the Two Houses of Parliament, in 1908, which emphasized the importance of making provision for electric power supply on a wider basis, there were passed between 1899 and 1905, about twenty-three Power Supply Acts, which cover all the industrial areas of the United Kingdom of any moment, and *prima facie* provide a solution of the question. The areas of these different companies are shown on the

SKETCH MAP SHOWING THE AREAS IN ENGLAND, SCOTLAND, AND WALES, OVER WHICH PARLIAMENTARY POWERS FOR ELECTRICITY-SUPPLY HAVE BEEN OBTAINED.



The Engineering Magazine

The companies holding the powers designated by corresponding numbers on the map are as follows:—1. Fife; 2, Scottish Central; 3, Clyde Valley; 4, Newcastle Electric Supply–Newcastle and District Lighting; 5, County of Durham; 6, Cleveland and Durham; 7, Yorkshire; 8, Lancashire; 9, North Wales; 10, North Western; 11, Derbyshire and Nottinghamshire; 12, Midland; 13, Shropshire and Worcestershire; 14, Leicestershire and Warwickshire; 15, Gloucester; 16, South Wales; 17, Carmarthenshire; 18, North Metropolitan; 19, Kent; 20, Somerset; 21, Cornw

Powers have also been granted to an Irish company known as the Shannon.

accompanying map. In these Acts, however, nearly all the towns in the respective areas having electric lighting stations, secured the right to exclude the local power company except by agreement, and many districts obtained electric lighting powers purposely to put themselves in a position to bargain with the power company. Thus it came about that although holding powers over important areas, when the districts in which most of the power companies were free to operate were examined after obtaining their acts, and after taking into account the exceptions which were granted at the instance of local authorities, it was found that as a rule the portions of them which the power companies could enter freely and which were of value were considerably restricted, their rights over the remainder being also to a a large extent only permissive and depending on subsequent arrangements being negotiated.

The full seriousness of this was not appreciated immediately as it was thought that by negotiation arrangements could be made within a moderate time with the authorities having these protective clauses to permit power supply in their areas, and that thus a position similar to that originally contemplated might soon be built up. On the north-east coast this has been to a great extent possible owing to the fact that the lighting of Newcastle was in the hands of a company which at an early stage amalgamated with the local power company, and thus a large going undertaking was quickly established and a moral effect created which has had an important influence in enabling agreements to be made with other local authorities.

In no other district in the United Kingdom, however, has there been such a favourable combination of circumstances, although there are other districts where the prospects of power supply apart from this question are as favourable, though perhaps more difficult to develop at the outset.

Attitude of Local Authorities.

Not unnaturally, local authorities are conservative in conceding rights which they think may be of value, and in the case of new developments it must be remembered that the old motto, *omne ignotum pro magnifico*, contains an important truth. Unfortunately, the form of procedure prescribed by Parliament in connection with the Power Acts, which was modelled on railway and tramway legislation, and was formed to deal with definite projects, was in many respects unsuitable for the presentation of the scheme of an undertaking which, starting from a centre, must be built up by degrees. This, in my opinion, led to the Power Acts appearing to be of a more aggressive character than they really were, and gave to outsiders the impression that undertakings of this character could be started and developed more easily and rapidly than I think even their most sanguine promoters imagined. Local authorities were thus led to the view that they would do well to stand off and await developments when it seemed probable that if the companies succeeded better arrangements might be effected than by an early agreement, and thus the development of most areas has been a tedious operation, though progress towards a better understanding is now making more headway. Again, as in the commencement of all important and complicated new movements, many mistakes have been made, and there have been many misconceptions as to what could or could not be done.

For these, then, and other reasons into which I will not enter, progress in developing most of these companies has not altogether followed the lines which were originally proposed and which would have led them first to develop the more urban districts of their areas where the preponderance of the smaller classes of power consumers are situated and the work is also more concentrated, and then to extend to the heavier industries in the more open districts afterwards. The opposition given by many towns to railways in the early days of these enterprises will be familiar to many, an opposition which has not ceased to be a detriment to these towns ever since. As time goes on, I believe that it will be found that history has repeated itself in the case of electric power supply. Debarred in a great measure from developing their business in the natural way, the power companies have been compelled to approach the heavier industries in the more open parts of their areas somewhat prematurely, and at the same time the fact that they were not free to enter some of the best parts of their respective areas reduced their initial commercial outlook, and led to their being started on a smaller scale than had originally been contemplated, a fact which is of much importance in this class of work.

Most of the power companies have, therefore, progressed more slowly than was anticipated, though a great amount of groundwork has been done which will tell later on. They are now getting a hold on the portions of their areas which are open to them, and are increasing their loads to a point which gives them a better command over the business, and should lead to more rapid development in the near future.

It was the attitude of the local authorities towards these undertakings at the commencement of what may be called the power supply movement that led Mr. Dixon Davies to read his paper on the "Cost of Municipal Enterprise" before this Society on the 3rd of February, 1899, and also the further paper which he read before the Society on the 30th of January, 1903.

Power Supply by Local Authorities.

The action of the power companies having brought the subject of power supply prominently forward, municipalities possessing stations, who opposed the entrance of power companies, were forced to move in the matter to some extent themselves, and in most of the large towns considerable efforts have been made, especially within the last two or three years, to meet the demand for power. Unfortunately in the returns that are made to the Board of Trade by electrical undertakings supply for power is not separated from lighting supply, and thus there are no official data as to the extent to which power is at present being supplied by local authorities.

The following are, however, a few figures available. Recent evidence shows that the local authorities in London are supplying over 20,000 horse-power for motors, and it has been stated by the engineer of the Manchester Corporation that the horse-power of motors connected to the mains there is in excess of 25,000, while at Glasgow the total exceeds 23,000. At Birmingham the load is increasing very fast, but owing to later development probably does not exceed half the amounts mentioned, though it no doubt will approximate to them later. In Sheffield, Leeds, Bradford, and other industrial towns a good deal has also been done towards meeting the demand, and nearly every town in the kingdom having an electric lighting station has made some effort in this direction.

In 1899, when Mr. Dixon Davies first drew the attention of this Society to the matter, local authorities had invested about £6,000,000 of public money in electric supply almost wholly for lighting alone. When he read his second paper, in 1903, this had increased to £23,000,000, a small proportion of which was for power supply. At the present date the sum is about £42,000,000. Probably of this latter sum £8,000,000 to £9,000,000 is due to arrangements for power supply apart from tramway and lighting supply; on the other hand, if the output in units is adopted as a basis, it will be found that the output for power is in many cases fast approaching that for lighting, and in some cases exceeding it, although it must be remembered that, on an average, about three units are sold for power at the price of one for lighting, owing to the longer hours over which the power demand is spread and the cheaper price at which the supply can be given. Nevertheless, in their eagerness to hold and secure power supply it is clear that many local authorities are doing this to a considerable extent at the expense of the lighting customers, who are bearing a disproportionate amount of the overhead charges. To some extent, undoubtedly, power supply must follow lighting, since many of the smaller power users can only be reached profitably off the lighting mains; but the supply of large individual consumers, often needing the expenditure of several thousands of pounds in the stations and in the mains to reach them, is another matter; yet this is not infrequently now being undertaken by municipalities.

Note.—*Statistics of Power Supply.*—Since these lectures were delivered, the *Electrical Review* has, by private inquiry, obtained returns from each central station in the country of the horse-power of motors connected. The majority of the returns relate to December, 1908, or March 31st, 1909, and are therefore approximately six months later than the writer's estimates as given in the lectures. They do not seriously differ from the writer's figures, but he takes the opportunity, with due acknowledgment to the *Electrical Review*, of substituting these later and more authoritative figures. According to this return, the horse-power of motors installed by customers taking supply from the public mains of stations owned by local authorities was 309,346 horse-power. On the same basis, the motors connected to the mains of electric lighting companies throughout the country, including London, working under Provisional Orders, was 118,625 horse-power. The following Table, extracted from the *Electrical Review* returns, shows the position of the power companies to date; the figures given in the lectures have been slightly modified to make them accord with these latest results.

ELECTRIC POWER COMPANIES.

Name of Power Company.	Power station capacity.	Maximum load recorded.	Total connections of all kinds.
	Kilowatts.	Kilowatts.	Horse-power.
1. Cleveland and Durham County Electric Power Co.	6,500	7,550	25,600
2. Clyde Valley Electric Power Co.	8,000	4,700	18,250
3. Cornwall Electric Power Co.	..	..	..
4. County of Durham Electric Light Co.	..	..	27,500
5. Derbyshire and Nottinghamshire Electric Power Co.	1,500	624	..
6. Durham Collieries Electric Power Supply Co.	11,000	4,927	11,563
7. Fife Electric Power Co.	600	..	..
8. Gloucester Electric Power Co.	..	..	..
9. Kent Electric Power Co.	3,500	800	2,433
10. Lancashire Electric Power Co.	8,000	2,450	5,000
11. Leicestershire and Warwickshire Electric Power Co.	..	..	..
12. Midland Electric Corporation for Power Distribution, Ltd.	6,200	3,822	8,500
13. Newcastle-upon-Tyne Electric Supply Co., Ltd.	47,000	37,400	103,961
14. North Metropolitan Electric Power Supply Co. (Four Stations)	11,450	6,320	13,381
15. North Wales Power and Traction Co. Ltd.	4,000	..	3,050
16. North-Western Electricity and Power Gas Co.	..	..	..
17. Scottish Central Electric Power Co.	2,700	800	..
18. South Wales Electrical Power Distribution Co.	C. 1,900	1,425	..
	T. 7,500	3,040	..
19. Yorkshire Electric Power Co.	6,000	3,393	9,497
Totals	125,859	77,251	228,735

CAPITAL OF POWER COMPANIES AND HORSE-POWER SERVED.

Turning now to the power companies, notwithstanding the difficulties they have had to contend with, the capital embarked in them stands at about £7,500,000, and they have some 126,000 kilowatts of plant installed besides plant in process of installation. The horse-power connected to the mains of these companies is, according to recent information, 229,000, with considerable additions on order. Of this total it is worthy of note that the companies working together on the north-east coast and covering the Newcastle, Durham, and Cleveland districts account for nearly half the capital expended in the whole kingdom, and that they have 136,000 horse-power of plant in their stations or in course of erection, while they are at present supplying manufacturing and electro-chemical and lighting works to the amount of 156,000 horse-power. This shows the possibilities of development when the field is open and opportunity favourable. It has recently been stated by Mr. Merz, the engineer of these companies, that for the power employed in the numerous works on the north bank of the Tyne 95 per cent. is being taken from the power company. These figures do not include capital spent by electric lighting companies throughout the country in power supply, which, including the London companies, may, I estimate, be fairly put at £4,000,000 to £5,000,000, nor does the horse-power given include that served by them, which probably approaches 100,000.

TOTAL HORSE-POWER OF PUBLIC SUPPLY BY COMPANIES AND LOCAL AUTHORITIES.

Thus in one way or another, by the power companies and by the companies in London and the provinces which were formed for lighting, motors are now being supplied with power from public stations established by private enterprise to the amount of nearly 350,000 horse-power. If we add to this the power which is being supplied by municipalities and given above, say 309,246 horse-power, the total approaches 660,000, which is the total horse-power of electric motors in the United Kingdom installed on consumers' premises and supplied from central stations with electric energy, while the total capital embarked must be in the neighbourhood of £20,000,000, an appreciable proportion of which, however, is in anticipation of further requirements.

The industry of power supply has therefore become a large one already, and we have

seen the further scope there is for it irrespective of the increase in the use of power which will certainly follow its being supplied cheaply and on an extended scale. That the position at present in large areas is in many respects a chaotic one will also be clear from what has been said above, and it must be manifest that it is very important that the facts should be considered on an impartial basis; and that further development in each locality should be arranged for on the best lines.

NOTE.—*Power Supply in France.*—Since the lectures were delivered, through the courtesy of M. A. Alby, the writer has received an interesting printed pamphlet giving particulars of the power companies in France. These companies are operated on much the same lines as the power companies in England but are doing a larger proportion of lighting. A much larger amount of work is done by means of overhead conductors which in one case extend to a distance of more than 150 miles. In France the physical conditions are not altogether comparable with those in the United Kingdom, being more favourable in some respects and less so in others. On the one hand there is in France, especially in the south, on the Swiss border, and along the Pyrenees, much more water-power than there is available in this country; on the other hand in France, outside one or two localities, there is not the concentration of manufactories within the limited areas which offer scope for power supply on a large scale as in a number of districts such as we have in this country. Nevertheless the course of the industry in France has been smoother and more prosperous than in this country. The total capital invested in the 23 French companies above mentioned appears to be about £10,300,000, and for this expenditure there are power stations having some 320,000 horse-power installed, of which about 230,000 horse-power is water power, and about 90,000 horse-power is steam, a proportion of the latter being reserve plant in case of failure of the water supply. Of the companies the largest is the "Energie Electrique du Littoral Méditerranéen." This company has a share capital of about £1,250,000, and obligations or debentures for an equivalent amount, so that its total capital is about £2,500,000.

PROGRESS IN PRODUCTION OF POWER GENERALLY.

After this brief review of the present position of electric power supply in the United Kingdom, we will now pass on to consider electric power supply as an industry in itself. Since the power supply movement seriously began in this country, about 10 years ago, there have been considerable changes and developments both in the generation and supply of power on the small as well as the large scale, so that the position is in some respects different from what it was in the earlier days of the movement. For generating power on the spot where it will be used we have had the acceptance of the high-speed engine for driving works electrically, and also there has been the advent of producer gas and the increased use of gas engines and oil engines, particularly of late the Diesel oil engine. By economies due to the use of these engines and other ways, what may be called the standard of the cost of power in this country has probably been lowered some 25 per cent. altogether. By this is meant not that power is being produced more cheaply where the old plant remains, but that where changes are about to be or have been made, manufacturers are able to get estimates showing some such saving as this by reconstructing their own supplies. Therefore in taking a supply from an outside source they have naturally put the one against the other, and thus it has come about that there has been, speaking generally, what may be called a fall in the market value of power to something like the extent mentioned within the last few years. On the other hand great economies in the cost of plant of large size, in its efficiency, and in the cost of distribution have also been made, and on the whole it can be fairly said that the practicability, economy, and desirability of generation and distribution on a considerable scale have advanced as much as on a small one.

CURRENT PRICES FOR POWER SUPPLY.

We will now consider briefly the class of prices which it is found manufacturers and others are prepared to pay for power supply from an outside source, and which consequently must compare favourably with the prices at which they can produce it themselves.

In the industrial areas for the smallest class of power users, who are for the most part supplied from low pressure mains, prices of 1½d. to 1d. per unit (1⅓ horse-power hours) enable electric supply to compete with the gas or oil engine which would otherwise be installed, and often to replace it. As the sizes of engines increase prices fall rapidly, the price of supply to ordinary manufactories working the usual hours and taking from 200 to 400 horse-power being from ·85 to ·75 of a penny per unit or thereabouts; when we come to larger supplies of greater regu-

larity, there are often discounts on these figures; again, for such loads as cotton mills, where the supply is both large and regular and for fairly long hours, prices of about ½d. per unit are being quoted, while for collieries the prices will range between ·7d. and ·4d., depending on the amount of pumping, fans, and other continuous work which goes to make up the load. Where the load is spread over the 24 hours and of fair magnitude the price will be about ·4d. to ·5d. per unit. Again, for large power supplies for the 24 hours continuously throughout the year, such as are used in electro-chemical operations and where the supply is near the power station, lower prices again prevail. I am aware of one large contract which was made for less than ·2 of a penny per unit, but a more usual price where the quantities involved are not so large is a farthing to one-third of a penny per unit.

Where coal is more expensive than in the industrial districts situated on coal-fields, the prices will need to be one-tenth to one-eighth of a penny per unit more to make up for the difference in the price of coal. In the towns it is possible to secure rather better prices than in the more open industrial districts, say to the extent of one-tenth to one-eighth of a penny per unit, as space is more valuable, and it is usually necessary to burn a rather higher class of coal to avoid smoke. It need hardly be said that such prices as those mentioned for cotton mills and collieries cannot be remunerative unless the station is of very considerable size, not less than 10,000 kilowatts for instance, or unless the circumstances are very favourable. On the other hand, in many of the industrial districts there is ample scope for single stations of 30,000 to 40,000 kilowatts capacity if the area is laid out to the best advantage, and in the larger industrial districts several of these stations linked together would be needed really to deal with the supply on a proper basis. In this case such prices as have been mentioned could be reduced, while still leaving a fair profit to the power supply undertaking.

In practice these prices are found to work out at from £3 to £4 per horse-power of motors installed per annum, which agrees well with what was said above as to the reduction in the market value of power, since a figure which was formerly current was £5 per indicated horse-power per annum as the cost of steam-engines of fair size worked under good conditions.

Influence of Capital on Cost of Supply.

The cost of supplying power varies largely with the quantity supplied and the hours of daily use, since out of every pound a customer pays for power for use during ordinary working hours, nearly 10s. is needed to cover a fair interest on the capital employed, depreciation, and contingencies; and as these vary very little, whether the supply is taken for a shorter or longer time per diem, the charge for power is often in practice made up of a fixed charge per annum on the maximum power supplied, together with a small charge per unit used, say, ·15d. to ·33d. to cover actual working costs.

Charging for Power.

The question of how power should be charged for is a very vexed one. To do this with theoretic fairness a double sliding scale is necessary, first to cover the price for different length of employment per diem, and, secondly, to accord with the quantity used, which latter is often accomplished by a varying set of discounts. It is found, however, that manufacturers object to these complicated tariffs, and as the knowledge of the average amount of work done in different trades increases there is a disposition to make contracts at fixed prices with a right of variation if, at the end of different periods, the recording instruments show that the power taken differs seriously from the contract amount either in quantity or rate of use.

Measurement of Power Supply.

Power is always measured by meter, often by a 2-rate meter, or by an attachment now frequently fixed to the meter by which the number of revolutions of the revolving disc in a given time, say half-an-hour, is counted and registered on a separate dial, the pointer remaining fixed at the end of each half-hour, when the mechanism resets itself. Thus no fresh movement of the pointer occurs until the number of revolutions in any half-hour exceeds the first, when the pointer is moved on to register the higher number, and this number multiplied by a constant gives the maximum horse-power taken during the half-hour. The same meter in this way can be made to register the highest rate of using power as well as the total number of units used. A check is thus kept on a customer's demand on the station as well as on the quantity of energy used. Owing to the ability of steam

turbines to carry overloads, and to their great fly wheel momentum, it is less necessary to be particular about short overloads than it was formerly, and there is a growing disposition to adopt simpler forms of tariff, which can now be done with fairness to both sides on the extended experience of power supply in different industries which is now available. New forms of recording wattmeters are also being brought out which act separately from the meter. There is, however, still room for more work in these directions, as satisfactory means of measuring power, and its rate of use, are of much importance in promoting confidence and good understanding between power users and power suppliers, and the inability to obtain satisfactory instruments of these types until recently, has had something to do with progress in power supply not having been more rapid.

Horse-power Employed in Different Industries.

The horse-power employed in different industries varies considerably; for instance, taking the light class of trades such as builders, small mechanics' shops, printers, and the large class of jobbing trades, the horse-power per man employed will be between ¼ and ½. Engineering works will usually take from ½ to 1 horse-power per man. Mines employ on an average about 1½ horse-power per man, varying from less than 1 horse-power per man for the smaller classes of mine to 2 and even 3 horse-power for modern collieries working on a large scale. In the textile industries the average appears to be about 1 horse-power per employee. In industries where there is much grinding, such as milling and cement making, the horse-power is higher, averaging 5 to 6 horse-power per man, and even more in modern plants. Again, in rolling mills, it may be very high, and in large electric power stations will amount to 200 horse-power per man or more. Taking, however, the general run of industries in a district, the power used will not average much over 1 horse-power per man employed; for instance, in London recent statistics show it is a little over ½ horse-power, while in the North, where the trades are much heavier, it will be double or more.

Cost of Power as Compared with Labour in Different Trades.

Now, having regard to the prices for power which have been mentioned above, it will be seen that in the majority of trades the cost of power in comparison with that of the labour employed is comparatively small. For instance, if the cost of power is ¾d. per unit, this is not much above ½d. per horse-power hour, while the wages per employee will perhaps average 6d. per hour or more; thus in the majority of trades the wages are ten to fifteen times the cost of power when this is supplied at the lowest modern prices. While, therefore, power is absolutely essential to the carrying on of nearly all industries, it will be seen that its cost is in most trades not a preponderating factor, though the capital cost of installing it, its proper working and the trouble of looking after it are of great importance. Nevertheless, even at these prices, power supply is a very large business if we consider that the supply in a large industrial area might easily necessitate the installation of 200,000 to 300,000 horse-power of plant, the revenue from which would probably be between £700,000 and £1,000,000 per annum. In addition, however, to supplying the industries of a district, the modern power station should also supply the energy for lighting and tramway supply, and it will have been seen that the power already employed in these two directions is in the neighbourhood of one-sixth of that employed in the industries of the country. It is also probable that, as railway electrification is carried out, a large proportion of the supply will be derived from the power supply stations of the districts through which the lines run. Then, again, there is electric heating, a development which, while only just becoming practical outside a very limited range, bids fair, as energy can be supplied at lower and lower prices, to become a very serious factor. There is thus a great further opening for power supply, though it is necessary to bear in mind that the supply of power to industries, and the price at which they get it, is not quite so fundamental an object as has sometimes been represented.

Advantages of Public Power Supply to Consumers.

Apart from the question of price, there are, however, a number of advantages in taking electric supply from a public source. Besides the saving in the cost of establishing local generating plant, there is the ability to obtain further supplies at short notice; for factory repairs and other similar work only the motors needed require to be run; there is no banking of fires or getting up steam preparatory to work; the risks of breakdown are less, with

chances of quicker execution of repairs, and finally there is the great advantage of regularity of drive. If the power supply comes from a large station where turbines are installed, working at high electrical pressure, both the pressure and the cyclic variation of the current can be kept within very narrow limits, and this, coupled with the special properties of multiphase motors which are almost universally used in power supply, enables an almost constant speed to be maintained. So much is this the case that it is being found possible in practice to speed up many of the machines in factories from 6 per cent. to 15 per cent. when driven by motor, and thus a larger output is secured without further capital expenditure and with but little addition to the labour needed. It is becoming recognised that the *quality* of power is of as much importance as the quantity and price.

This has proved to be the case especially in the textile industries and in the rolling of iron and other metals. It is also found so in engineering shops where work can be turned out at a greater rate, while the regularity of the speed is of importance in securing accuracy.

There are also the more general advantages obtained by the saving of coal, as already mentioned, and by the reduction of smoke in industrial districts, which alone are sufficient to warrant every encouragement being given to the extension of public power supply.

THE PRESENT POSITION.

Such, then, is briefly the present position. The figures given indicate that a larger amount of work has already been done in power supply from public stations than I think most people imagine, but it is also clear that hardly more than one-sixth of the work which there is scope for has been done as yet, especially if the political and legal conditions were such as to enable supplies in each district to be laid out on the best engineering lines.

It is, therefore, important to inquire what these are as far as can be done, bearing in mind that local conditions will in nearly all instances to some extent modify such conclusions, though probably not greatly, since the figures relating to power supply undertakings in different parts of the country which are now becoming available indicate fairly close correspondence.

DRAWBACKS TO PUBLIC POWER SUPPLY.

Power supply from a central source has, of course, some disadvantages and drawbacks to contend with, which must be taken into account as compared with power generated where it is required to be used, and these should always be debited against it as a precaution, and then be compared with its advantages in order to arrive at a correct understanding of the question.

For instance, in public power supply there is the initial handicap that legislative powers must usually be obtained before it can be undertaken, and this always weights the enterprise, especially if private, with an amount of dead capital, which in this country is unfortunately very considerable, and forms a material handicap in the early stages. In the next place, a separate board of directors and management is requisite, while manufacturers as a rule will not debit their own power costs with any material sum under this head, though it is really an item of considerable moment, even if difficult to apportion. Rating and taxes will also be higher for the public supply, and lastly there is the most important item, namely, the distributing system, which, both as regards its capital cost and the running losses which occur in it, is an addition to the generating station costs. A central power station also has the disadvantage that it has usually to be built considerably in advance of the possibility of obtaining the full beneficial use of the plant it contains; therefore capital costs have also to be added in most cases to cover expenses incurred until the station can accumulate sufficient load to pay its way, whereas a manufacturer usually only puts in plant which he is ready to use at once, though it may not be quite to its full capacity. There are a good many reasons, therefore, why a central power supply is not an easy business to start, especially if it is separated from lighting, and has to be begun off the ground, and, consequently it is particularly desirable that such a business should receive encouragement in its early stages, and should not be overloaded with onerous conditions which later on might be borne easily, but which at the commencement may overweight the enterprise altogether.

ADVANTAGES OF POWER SUPPLY—DIVERSITY FACTOR.

Against these drawbacks we have to credit the advantages already mentioned, and also the material gains which can be obtained by centralisation and working on a larger scale. These will be dealt with in detail later.

There are also two general advantages obtained by supplying from a central source

which are very important when the source is of considerable size, and with which it will be best to deal briefly before discussing power supply more in detail, viz., the diversity and load factors. By diversity factor is meant that when a number of separate supplies are grouped together, they are not all taking their maximum amount of power at the same time, and so much is this the case, that it is found in practice that if a large number of small consumers are taken together, the output to supply them all from a central station need not be more than a quarter to one-third of the horse-power to which the separate engines would have amounted if each consumer generated his own supply, and used his maximum power at the same time. In the case of large consumers having a number of motors on their own premises, it is found that the total power they require is seldom more than one-half to one-third the rated horse-power of the motors they have installed. Again finally, when the loads of these larger consumers are averaged at the power station there is a gain of about 30 per cent., and often more, depending on the class of load, so that the diversity factor of large consumers will work out at over two, as a rule, if estimated on the motors installed and their horse-power, and at nearly 1·5 on the maximum loads, treating each consumer, however large, as one unit. In this connection it is becoming very desirable that engineers should agree on a more accurate definition of diversity factor by defining more precisely what is to be taken as the maximum load.

For these reasons, practice shows that on large stations giving supply to miscellaneous industries, two and a-half to three times the output of the station can on an average be installed in motors at consumers' premises. Thus it is only necessary to debit something less than half the capital cost per kilowatt of the station and mains against each kilowatt of motors installed in customers' works.

On the other hand, if we look at the diversity factor as related in the consumers' maximum loads, treating each consumer as one unit, it is probable that the diversity factor regarded from this point of view will not increase much with the growth in size of power supply, as a larger proportion of consumers having many motors will be taken on who will have already averaged the maxima of the motors in their own works.

Load Factor.

Our next point is the load factor, that is, the amount of energy supplied from a station as compared with what would be supplied by the station if it was working continuously all the year round at the maximum load supplied by it; it is, in fact, the ratio of what is actually got out of the plant brought into use as compared with what could be got out of it under the most favourable circumstances.

From what has already been said of the diversity factor it will be apparent that the load on the central station will be much less than at individual works. For instance, it is found that the smaller classes of power consumers usually use their motors to an extent which represents less than 10 per cent. of the rated output for the hours of work, and often it is only half this. When we come to larger works employing several motors the load factor will rise to 16 per cent. or 18 per cent., and in considerable manufacturing works it is probably as an average something under 25 per cent. For textile mills the load factor will again be better and when we come to works operating all night, the load factor may reach 60 per cent. or more, while for electro-chemical work it is between 80 or 90 per cent. usually. Although the average time of employment of motors is in the majority of instances comparatively short, they are liable to be operated any time during the working hours, but owing to the diversity factor their loads are spread out, and thus the load factor in the central station is far better than the average of that of the consumers. Again, a large power-supply station will, as a rule, be able to average its customers better than a smaller one, and thus will secure a better load factor. This means that the working costs per unit in the larger stations, which are for the most part nearly constant in a station, except in the item of coal, can be spread over a greater number of units, and are thus correspondingly reduced.

As between smaller and larger stations it is somewhat difficult to define what the increase of load factor will be as it will depend on the trades in the district, but it may be fairly put that if the load factor of a 2,500 kilowatt station is 26 per cent., that of a 40,000 kilowatt station operating under similar circumstances would probably be 35 per cent. at least, and not improbably more, as the larger station will have a much larger proportion of customers of considerable size, whose own loads would be better. This means an improvement of over 30 per cent., and if we take the extra coal used for the longer working load and allow for other items of increased cost, it still means a saving

of about 10 per cent. in the working costs owing to this fact alone, which is an important item. Later on we shall have occasion to refer to special methods of improving the load factor.

HOME INDUSTRIES.

The Crisis in the Coal Trade.—Most happily, the Conciliation Board for the South Wales coal trade seem to have arrived at a settlement of the dispute which threatened to involve the whole of the collieries of the United Kingdom. The Eight Hours' Act came into operation on July 1, and the coal owners had given notices which expired on the night of June 30, so that they might be able to insist upon a fresh system of working in the altered cases. As previously explained in these Notes, their chief demand was that they should be at liberty to order double shifts when they thought fit. With that conceded, settlement of the general dispute was always in view. It was not very easy to understand the men's objection, seeing that the system works well elsewhere, but the difficulty has been got over by the owners agreeing to the miners' proposal that all such proposed changes shall be submitted to them for consideration before adoption, and that all objections to any such new methods shall be submitted to the Conciliation Board for decision. But this is subject to an undertaking being given by miners' leaders to raise no obstacles to new methods of working when their introduction into particular collieries has been agreed to locally. Another somewhat serious point of contention was the owners' demand that the men must work the sixty extra hours per year which the Act allows. It is agreed that this question shall be tested by taking a case to a court of law. The question at issue here is in essence one for the interpretation of the courts to settle, and the entire community is to be congratulated upon owners and miners having had the good sense to appreciate this.

Short Time in Cotton Mills.—The ballot shows that a majority of the Master Spinners' Federation who spin American cotton are in favour of organised short time for most of the next three months. The mills of the Federation, and as many of those of outsiders as can be induced to join, will close on Saturdays and Mondays from the middle of this month to the end of September. Spinners have been losing money on staple counts of yarn for some time, and though most of them are still paying dividends of 10 per cent., they are not earning them, the payments coming from reserve funds, and they can hardly last very much longer if drawn upon to the same extent. The reports as to the condition of the new cotton crop issued by the United States Department of Agriculture are less favourable, and though there is no cause to fear a cotton famine, it is probable that cotton prices may remain for some time too high for any large buying by the chief markets. In these circumstances some limitation of the output would seem to be necessary, and, indeed, there has been a good deal of voluntary short time in the spinning trade for some time past.

Gas v. Electricity.—Two or three years ago it was argued at some length in these Notes that as an illuminant gas was likely to be a much more formidable rival of electricity than was generally supposed, and therefore the prevailing assumption that electricity must oust gas was by no means demonstrable. It was contended that as to convenience, there was little to choose between the two, since by means of a by-pass on the burner instantaneous light without the aid of matches can be secured by gas, whilst in the matter of cost the advantage was decidedly with gas. Since then the comparative advantages of gas have become much more apparent to the ordinary consumer. It is not only that gas may be as convenient and is much cheaper, it is more dependable. Breakdowns with electricity, over the whole supply as well as individual cases, are not uncommon, but with gas there is no such irritating possibility. From whatever point of view the comparison is made between gas and electricity, except perhaps in the matter of cleanliness, the former holds its own, whilst the saving in cost is very great. It may be safely said that, speaking generally, electricity is twice as expensive as gas, and under certain conditions the ratio is even higher. The present position of the rival illuminants is in striking contrast to what it would have been if the predictions of the experts a few years ago had been fulfilled. Many gas consumers were frightened into the belief that the gas companies would soon be within sight of bankruptcy; their outlook to-day is much brighter than ever it was. This, of course, is largely due to the rapidity with which gas is now superseding coal as a heating agent. It is more convenient in every way, and with the substitution of gas for coal, the atmosphere of great towns, and more especially London, must be immensely improved.

Railways and the Land Clauses.—It is understood that the railway companies have received satisfactory assurances from the Chancellor of the Exchequer as to exemption from the taxes on undeveloped lands and minerals. It would be eminently unfair to impose such taxation. The unused lands of the railway companies were bought and paid for, always at a high price, just as the other lands bought by the railway companies were purchased, for railway purposes, and it does not alter the position that all of them have not hitherto been used for such purposes. Moreover, railway companies do not work the minerals under their land, because, for one reason, they require the support of the underlying ground for their traffic.

Banking Profits.—The one or two bank dividends announced at the time this Note is written tend to confirm the expectation that the past half-year would

show rather unfavourable results. A rough test is afforded by what is called the "profit margin,"—that is, the difference between the interest paid to the depositor and the amount the bank obtains by investing its money in bills. For the six months to June last the average rate for three months bank bills was £1 17s. 9d. per cent., and the average rate allowed to depositors £1 4s. 3d. per cent., which shows a margin of profit of 13s. 6d. per cent. This compares with 15s. per cent. in the second half of last year, with 18s. 6d. in the first half of 1908, and with £1 11s. in the second half of 1907. The average rate for day by day money was a little under 2 per cent. against nearly £2 15s. per cent. in the first half of 1908, and the average rate obtained for loans to the Stock Exchange was a little under 3 per cent. against 3¾ per cent. last year.

The Shipping Trade.—The outlook for freights is better than it has been for some time past, although the conditions, especially in the North Atlantic, are still anything but good. In their review of the shipping trade of the past six months, Messrs. H. E. Moss and Co., of Liverpool, say that modern tramp steamers can now be worked so as at least to earn interest and depreciation, which is more than could be done for some time past. The tonnage laid up has been reduced to less than one-half, and that remaining idle is practically out of date. Messrs. Moss and Co. estimate the amount of obsolete steam tonnage at fully one million tons. The prices for building steamers were never lower, mainly through the improved means of construction builders have now adopted. New steamers, with 6,000 to 8,000 tons, with fair specifications, can now be placed at about £5 5s. per ton on the dead weight, and other sizes in proportion. Most of the new steamers left on builders' hands two years ago have been disposed of, and the majority of bargains in the way of comparatively new steamers have been picked up. Indeed, throughout the recent crisis there were very few forced sales, which proves that the bulk of shipping is held in much stronger hands than formerly. Second-hand steamers have been difficult to sell, the depreciation of this class of property being much greater than that of new tonnage.

Wheat Supplies. — The indications continue to point to the present price of wheat being not only maintained but exceeded in the coming months. The high prices of the spring led to some farmers selling their crops with unusual freedom in the first half of the season, and the same remark applies to Germany. That country requires about nine million quarters of foreign wheat to meet its requirements, but only five million quarters were imported net in the first ten months of the season ended May. Our own requirements of foreign wheat for the season may be put at twenty-seven million quarters, but up to May 31 only 19,227,000 quarters had been imported, so that about 7,500,000 remain to be imported before the end of July, whereas last year 3,920,000 quarters were found to be sufficient. Thus between them Germany and England require to import between 11,000,000 and 12,000,000 quarters in the two months ended July. On the other hand, the world's visible supply on July 1 was only 9,050,000 quarters as compared with 9,835,000 quarters in 1908 and 16,680,000 quarters in 1907. Of course much will depend upon the coming harvest, but if reports are to be relied upon, at best it is not likely to be better than an average one. No doubt high prices have induced economy in the use of wheat, but there must be much greater economy, both in this country and in Germany, or else a more extensive use of substitutes before the new wheat becomes available. But in any circumstances, and remembering that the "invisible" supplies of wheat this year are smaller than they have been for many years past, high prices for wheat must be reckoned with for a considerable time to come.

Coalite.—Two or three years ago considerable interest was shown in "Coalite." A company with large capital was formed to work it, and great results were promised. As so often happens, experience has not borne out the confident predictions of inventors and promoters. A circular has recently been forwarded to the shareholders of the company which purports to explain the present position, and shows how expectations have been disappointed. In commending coalite to the public particular stress was laid upon the fact that in its manufacture the ultimate object was not the production of gas or tar, but of fuel, and that the residue in the retort, which in the manufacture of gas was only a by-product, was in the manufacture of coalite raised to the rank of the staple manufacture. Now coalite is officially reduced to the rank of a by-product like ordinary coke in gas-works. The directors state that they expect to derive their chief profits from the distillation of tar. It was claimed, again, that coalite required hardly any draught to burn, but it now appears that at Plymouth slow-combustion grates have to be used, and that in open-draught grates a certain method had to be adopted to make them consume coal economically. It was anticipated by the promoters of coalite that, being more economical than coal, it would replace the latter for steam-raising purposes, and that it would be the fuel of the future for the navy. The circular is silent upon these expectations, and there is nothing to show that they have been, or are likely to be, realised.

OBITUARY.

LIEUT.-COL. SIR WILLIAM HUTT CURZON WYLLIE, K.C.I.E., C.V.O.—The whole country was shocked and horror-stricken to learn of the assassination of Sir Curzon Wyllie, which took place

at the Imperial Institute on the night of the 1st inst. As full details of the crime have appeared in the press, there is no need to record them here.

Sir Curzon Wyllie was the youngest son of the late General Sir William Wyllie, G.C.B. He was born in Cheltenham in 1848, and after being educated at Marlborough and the Royal Military College at Sandhurst, in 1866 he joined the 106th Regiment as ensign. Thirteen years later he was transferred to the Political Department, and served in Baluchistan under the late Sir Robert Sandeman during the Afghan War in 1879-80. He was also chosen to accompany General Sir Robert Phayre's force to the relief of Kandahar, carrying despatches, for which he received the medal.

Among his many activities as a servant of the State in India he was also military secretary to his brother-in-law, the late Right Hon. W. P. Adam, Governor of Madras, in 1881. He was also private secretary to Mr. Hudleston, who acted for a few months as Governor on the death of Mr. Adam. Other positions successively held by him were those of Resident in Nepal, Governor-General's Agent in Central India, and Governor-General's Agent in Rajputana. On his retirement as Lieutenant-Colonel in 1901 he was appointed Political A.D.C. to the Secretary of State for India, a position which gave him many opportunities of helping Indians resident in London. His kindness of heart and genial courtesy gained him many friends, both Eastern and English; and the assassin's act deprived young Indians visiting London of one of their best and kindest advisers.

For his various services Sir Curzon received many distinctions, including the C.I.E. in 1881, the K.C.I.E. in 1902, and the C.V.O. in 1907.

Sir Curzon became a member of the Royal Society of Arts in 1907, and at the time of his death was serving on the Committee of the Indian Section, in the work of which he was deeply interested.

QUESTIONS AND ANSWERS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTION.

TREATMENT OF SLAG FROM THE CUPOLA IN GENERAL FOUNDRIES.—What is the best method of recovering iron from the slag? I generally return the coke and slag adhering to it to the cupola, but is the "fluid" slag run off at the end of the day worth treating? I understand machinery has been used for grinding and washing slag for the recovery of iron, but it does not seem to be in general use; so far I have only come across two instances. What would be percentage of iron in the "fluid" slag run off, and is there a machine that would pay for treating this?—J. H. H.

GENERAL NOTES.

THE COST OF A PAUPER.—In the Statistical Memoranda and Chart just issued by the Local Government Board, relating to public health and social conditions, there are some interesting figures bearing upon the average annual cost of an indoor and out-door pauper, the comparison being between that of the years 1856-7 and 1906-7. The figures relating to 1906-7 may be taken as accurate, but for the earlier years they are approximate only. They work out as follows:—

	1856-7. Cost per head (approx.).		1906-7. Cost per head.
To paupers in Poor-law institutions	£16 12	..	£29 5
To paupers in receipt of out-relief	4 13	..	7 1

The total cost has increased from £5,521,000 to £11,559,000; the average cost for indoor paupers has increased 75 per cent., and for out-door paupers 52 per cent. The sick and infirm need more elaborate treatment than do the able-bodied poor, and the relative increase of this class of poor has been accompanied by provision for their accommodation and treatment in special wards or institutions on the lines demanded by the development of medical and surgical practice. The accommodation for children in separate institutions, and the necessary appointment of a suitable staff for their management, have equally involved an additional heavy expenditure. The bare comparison of the cost per pauper over a period of fifty years conceals both the change in the character of the persons dealt with by the Poor-law, and the specialisation of treatment which accounts for the increase in the cost of their relief. The higher rate of relief to out-door poor is largely explained by the fact that in contrast with the practice half a century ago out-relief is now largely limited to the class of aged and infirm, who are permanently or semi-permanently disabled. It has thus become possible to grant relief on a scale more nearly adequate than formerly.

CANTOR LECTURES.

THE PUBLIC SUPPLY OF ELECTRIC POWER.

By G. L. Addenbrooke, M.I.E.E.

PART II.*

Capital Cost of Electric Power Stations.

After having outlined the general position we now come more directly to the consideration of power supply undertakings in themselves. For this purpose we will first deal with the capital cost of creating public supply undertakings, and then with their working costs, showing approximately how these vary with varying conditions, and as the size of the undertaking is increased. Various attempts have been made to do this by different engineers in papers and in the technical press by means of curves, but the lecturer has found in his personal experience that the best grasp of the subject is obtained by inspection of a set of Tables such as those now given. These have been deduced from data in the lecturer's possession, and compared with figures which have been put forward from time to time by other engineers.

The lecturer puts these Tables forward with some diffidence: they must in no sense be considered as a ready-made guide to power station practice. Experience shows that when any practical work is undertaken there will always be local circumstances and conditions which will make each project unique in itself and result in a considerable variation from a standard favourable or otherwise, besides the fact that such undertakings are usually built up by steps and are not evolved as a working whole at once. Nevertheless, such Tables are useful because they bring most of the facts before us in a concrete form and in a way which enables us to estimate the relation of each item to the whole, and what is of even more importance, the extent to which variations in one or more items will affect the whole.

They are in fact to be looked on as equations in which the quantities involved in the supply of electric energy are represented by their most likely values for each size of undertaking, though there may be considerable variations in any or all of the items under special circumstances.

It is particularly necessary to bear this in mind, because owing to electric power supply in this country being partly established as an independent industry and partly being financed by money borrowed at low rates of interest on the public credit, two different bases of value are created, and this greatly complicates any comparative treatment of the subject. What I have done is to prepare the Tables on the assumption of the industry being self-supporting, which is the sound economic basis. The variations and reductions obtained by financing with public funds at a low rate of interest are, then, a measure of the support which the Government and local authorities are giving by borrowing on the credit of their other assets. (See Table, p. 712).

Capacity of Stations.

First, as regards the capacity of the stations, the sizes given are intended to represent the actual output of the stations, so that the plant installed can be taken as one-third for the smaller sizes to one-fourth for the larger, more than that shown. For a permanent plant which is not going to be enlarged, the convenient way is to divide it up into eight units, of which two would form the reserve. In

* The Course consisted of three lectures, delivered on January 18 and 25, and February 1. In re-arranging the material for publication, the lecturer has preferred to divide it into four parts.

stations in a district where the load is likely to grow, however, it is usual to instal larger sets than this would imply during the initial stages, and to trust to the overload capacity of the generators to tide over any difficulty should more than one set be out of commission at a time.

The chief feature of this Table is the reduction in the capital cost, according to present practice, per kilowatt; as the size of stations is increased, this reduction, it will be noticed, is progressively less as the larger stations are reached. At present there is probably not much gain by going further in size, though several stations already of greater capacity than the largest given in the tables have been built. The capital costs of power stations are now well ascertained, and those given will be found to agree closely with work which has been carried out and with the estimates of the price which a simple works plant of 300 to 500 horse-power could be erected for without spares or coal and labour-saving refinements. It is, however, seldom that a works can hit off the exact amount of power it requires, there must usually be some margin, and even if no spare steam or electric plant is installed it is necessary to have spare boilers, so that altogether the cost of private plant of this size will be above the cost of the smallest central plant given. For still smaller private plants the costs will of course be higher again per kilowatt.

With the spare plant provided in the above stations there would be no difficulty in maintaining absolute continuity of supply under all circumstances, whereas a private plant without spares must inevitably have an occasional shut down.

I.—Approximate Capital Costs of Electric Power Supply Undertakings.

Available output of station K.W.S.	Cost of power-house per K.W. available.	Allowance for distribution system per K.W.	Parliamentary expenses, cost of finance and working capital, per K.W.	Total costs per K.W. available.	Capital cost of undertaking.
	£	£	£	£	£
2,500	24	20	12	56	140,000
5,000	20	16	10	46	230,000
10,000	17	14	8	39	390,000
20,000	15	12	6	33	660,000
40,000	14	10	5	29	1,160,000

One kilowatt equals 1⅓ horse-power nearly.

other engineers. It is well to note that in the largest size of station in the Table there is nothing outside everyday practice, as several of the large towns—and power companies—are now having installed steam turbines of 5,000 to 6,000 kilowatts capacity, the price of these being about £4 per kilowatt including the dynamo and requisite condensing plant, and erection, this sum being about one-third of what was paid a few years ago for large slow-speed reciprocating sets to do similar work.

The figures shown are conservative, and it must also be recollected that there is a continual tendency for the price of plant to fall. In fact since the figures were prepared there has been such a reduction in prices, and under favourable circumstances and with cheap buildings the figures given could at present probably be reduced 10 to 15 per cent. The highest of these costs comes to about £16 per kilowatt of plant installed, and this is about

Distribution.

A proper figure to cover this is always a vexed question with engineers; the figures given in the Table are, however, borne out in practice, for the smaller sizes and the larger have been carefully estimated and agree with figures arrived at by other engineers. In the smaller stations the distribution is assumed to be up to about six miles from the station, and in the larger up to eight or ten, or a little further on favourable routes. These figures do not include costs of local distribution for lighting or of sub-stations for transformation of the alternating to a continuous current for tramway or railway supply. Out of the costs about £4 per kilowatt will be for transformers and switch gear in the smaller networks and about £3 in the larger, the remainder of the costs being for cables, laying, jointing, joint boxes and sub-stations.

The reason for the fall in the cost as the size

of the system increases is that the smaller stations cannot supply current so cheaply as the larger ones and therefore can only deal with customers up to certain sizes, and so have to go further for their custom on an average and also employ smaller cables. For instance, it is in power supply work a good rule to bear in mind that for a central supply to be able to deal advantageously with consumers, as compared with the costs at which they can make their own power, the largest customer should not exceed in size one-tenth the capacity of the station serving him, and it is better to keep within this ratio if the distance of transmission is long. Until this proportion is reached the special charges which the central station has to bear will often offset the gains of economy in other directions. The cost of laying the classes of cable used in this work are very much the same whatever size is used, and the cost of the cable itself by no means increases proportionately as the section is larger. The following data will show this for sizes of cables which are much used on the 11,000 volt distributions which are usual in this country:—

Section of cable.	Approximate carrying capacity kilowatts, up to	Cost laid per mile.	Cost per kil. Capacity per mile.
		£	s. d.
·05 sq. in.	750	900	22 0
·10 ,,	1,500	1,200	16 0
·20 ,,	3,000	1,700	10 6

It is also the case that the smallest sizes of branch cables which are laid to works have usually a much greater capacity than they are used for, and this will be much less the case with large distributing systems where the price of current is low and it is taken in greater quantities. The cost per kilowatt of transformers and switch gear is also very much less for larger supplies, especially switch gear, which is almost a standard pattern for such work as is found in sub-stations and in consumers' premises. It is probable that in practice the cost of the distributing systems for the larger undertakings will usually be greater in practice than is shown, because there will be a tendency to extend into the less profitable and more distant parts of the area, charging rather higher prices for supply to balance the increased capital cost, but this is a development which will rest on its own basis and does not affect the accuracy of the figures in representing the lowering in cost from increased scale of working, and the actual costs which are likely to be incurred in the disposing of the amount of energy mentioned within the more central parts of the better industrial area of the United Kingdom.

Preliminary Costs and Finance.

We now come to an item which may differ largely in different cases; that for preliminary costs, costs of finance and working capital, together with all those other extraneous items which have to be met in establishing a business. Unfortunately in this country the costs to private promoters of obtaining Parliamentary powers for an undertaking of the kind we are discussing are heavy, and not only is there this expense but there will in most cases be in addition long negotiations with local authorities, which always means having to pay the costs of both sides in some form or other. The cost of finance is also considerable in starting new undertakings, and in the lecturer's experience there are always a number of expenses in the early stages of all undertakings which must be met, but which cannot be brought under either of the two previous headings. For instance, even corporation loans are often raised at a discount, and there are the expenses of raising them, which must be debited somewhere, and heavy cost has sometimes to be incurred for the purchase of land; then there is the working capital of the business, and often interest on capital to be paid before the undertaking comes to fruition.

As power-supply undertakings increase in size and become paying propositions promoters will be able to raise money more and more cheaply, but I have still debited a considerable sum of extraneous expenditure under the head, as when an undertaking of this kind grows to large dimensions it often has to buy out smaller stations or compensate them in some way by doing unremunerative work, such as lighting poorer districts. As an instance, I may mention the Newcastle company as having already shut down 11 small stations, scrapping capital value of nearly £300,000. This is an important point for those interested in industrial districts to bear in mind; if the smaller stations are allowed to increase unduly and then have to be scrapped, and if comprehensive schemes are not initiated in time, it may result in both local authorities and companies being out of much of the field of power supply, and at the

same time prevent as cheap and efficient a service being given to manufacturers as could otherwise have been arranged. Altogether, therefore, the figures put in this column are in accord with facts, though I must confess that, for the benefit of power and light consumers, it would be a very good thing if they were less, and this could be accomplished to a considerable extent if electrical enterprise were treated with more consideration and encouragement in this country.

The last column shows the total capital which will approximately be needed for each size of undertaking.

We now come to the working costs of such stations, to investigate which we must first agree on certain working data which are set out in Table. II.

Station Working Data.

The load factors are taken at the figures mentioned in the first lecture as those most likely to be obtained. For pure power supply they are I think unduly conservative, which makes the average prices given later rather higher than they would turn out in practice; but few stations will exist any length of time without supplying a good deal of current for lighting, which raises the average price and lowers the load factor. It should also be noted here that several of the power companies are now supplying current for electrolytic and similar long hour work to factories situated close to them. The working hours for this class of load being nearly the maximum possible, this secures more constant work for the plant and spreads out the capital and other charges over a much greater output, enabling a general reduction of prices to be made.

The number of units sold follows from the load factor. The lbs. of coal used per unit of energy sold have in each case been deduced from the best modern practice.

Usually speaking, when we come to deal with such small quantities of coal, the number of British thermal units used should be quoted instead of the lbs. of coal, as it is on the number of British thermal units in the coal that its steam raising power chiefly depends.

Take the class of coal assumed to be used as giving 11,500 to 12,000 British thermal units per lb. On an average the largest station will use 38,000 to 40,000 British thermal units to supply a customer with one Board of Trade unit. Thus it results that the overall efficiency of the plant from the coal to the consumer is a little over 8½ per cent. in the larger stations. For the 2,500 kilowatt station the overall efficiency is about 6 per cent. This is up to the consumers' motor terminals, and does not include the losses in the motors themselves, which would probably bring down the overall efficiencies to 7½ and 5½ per cent. respectively.

The price of coal assumed is about that paid by power stations in industrial districts for the class of coal they use in normal times, and from the way the tables are made up, it is easy to see the effect of any alteration, either in the quantity used per unit sold or in its price. For instance, the cost of carriage to London adds about 6s. per ton to the cost of coal in the coal-mining districts. These figures will also be very useful when we come to consider the possibilities in the substitution of gas engines for steam engines or turbines, on the use of which latter it need hardly be said the Table is made up.

II.—Station Working Data.

Available output of station K.W.S.	Load factor.	Sold to customers per annum.	lbs. of coal per unit sold.	Coal cost per unit sold at 6/8 per ton.
	Per cent.	B.T.U.	lbs.	d.
2,500	26	5,700,000	5·25	·188
5,000	28	12,200,000	4·50	·160
10,000	30	27,000,000	4·00	·143
20,000	32	54,000,000	3·50	·126
40,000	34	116,000,000	3·25	·116

Annual Working Expenses.

The sums set down for administration and labour have in the smaller cases been taken from the lecturer's experience and from practice; in the cases of the large plants the items have been arrived at after careful consideration; for instance, take the 40,000 kilowatt station, the administration charged in

the Table is in excess of that incurred at Manchester according to their last accounts. It is true that the maximum load at Manchester was only 28,000 kilowatts, but it is an old and scattered undertaking in many respects, and the charges also include looking after the lighting and also after tramway sub-stations, for which an extra price is obtained. Such work is not included in the costs in these Tables as it differs so much in different cases, nor is the cost of a canvassing staff, which is in a large measure a capital charge. In practice also work will be done for consumers, but this should take care of itself. The working costs in these Tables cover transformation of the multiphase high pressure current to any suitable working pressure, and its supply to manufacturers or others, or to sub-stations for lighting or tramway supply, but the costs of distributing the energy through local mains for lighting, or the costs of transformation from alternating to continuous current, are intended to be dealt with separately.

III.—Annual Working Expenses.

Available output of station K.W.S.	Administration and labour.	Coals 6/8 per ton, oil, water, and stores.	Rent, rates, taxes, and insurance.	Repairs and maintenance.	Total costs.	Cost per unit.
	£	£	£	£	£	d.
2,500	4,200	4,900	1,500	2,500	13,100	·550
5,200	6,500	8,900	3,000	4,000	22,400	·440
10,000	11,000	16,000	6,000	7,500	40,000	·360
20,000	18,000	30,000	12,000	12,000	72,000	·320
40,000	30,000	60,000	24,000	22,000	136,000	·280

It may be mentioned that the costs of administration and labour respectively are not far from equal in most cases. The cost of labour allowed is less than in the case of the Manchester undertaking, but it has been carefully compared with the work and estimates of other engineers for modern stations, and assuming that most of the energy is sold in fairly considerable quantities. The fall in the costs per kilowatt output of plant, as the size of the undertaking increases, is very remarkable, but is borne out by results already attained. In a power station the attendance needed is rather governed by the number of moving or working parts than by their size. For instance, the smallest size of station in the Table will need turbines and dynamos of 500 to 750 kilowatts capacity, while the largest would probably be fitted with 6,000 kilowatt sets, which are the largest size now being regularly made. But each of these plants has to all intents and purposes the same number of working parts, such as governor, bearings, pumps, exciter, &c., together with the various indicators, gauges, &c., which have to be watched to control the working of the plant, and it is very nearly as much trouble to maintain the smaller plant under observation and perform the various adjustments which have to be made to keep everything going properly, as to do this for the largest set. The same reasoning applies to the boiler-house, though not quite to the same degree. Again with the distributing system, if we double the output, we shall not have to double the length of mains, or the number of consumers, at the larger output the price will be less, and larger consumers will be obtained, and on an average at shorter distances along the mains, moreover few organisations need to be doubled to do double the work. Altogether, therefore, it is clear that the gains by consolidation, shown in the Table, are moderate, and may even be exceeded in practice.

The question of coal consumption has already been mentioned, and will be dealt with later on, when we come to discuss technical points.

Rent, rates, taxes, and insurance are rather debatable items, but the sums allowed have been fixed after careful consideration of the similar costs in existing undertakings.

The amount allowed for repairs and maintenance averages nearly 2½ per cent. on the value of the plant. New plants will be able to do with a much smaller allowance, but it is assumed that the plants we are considering have been in use long enough to need the average amount of repairs; this is irrespective of the sums which are allowed for depreciation later, and which amount to three per cent. on the capital expended. As cable makers will agree to maintain distributing systems for one per cent. on their cost, and buildings, and a good deal of other works do not need much

maintenance this leaves a very substantial sum for these parts of the plant which do need a good deal of renewal, and the antiquation of which must be provided for.

Total Cost per Unit.

With these various items before us, we can now estimate the total costs per unit of supplying energy including all expenses, except interest on capital and depreciation, and the figures will be found instructive. It will be observed that, commencing at rather over a half-penny per unit sold, as the scale of operation is increased the costs come down to a little over a farthing per unit sold, or to one-half, and notwithstanding this reduction, it will be found on inspection that the allowances are really more liberal for the larger stations than for the smaller.

In work by local authorities the allowance for interest and sinking fund under this head is often not more than 6 to 6½ per cent., but my convinced opinion is that when all is said and done power supply is and must remain for a good many years at any rate a trading adventure, a very legitimate one and one likely to be sound and successful in the long run, but, nevertheless, one which ought to carry an all round profit of at least 5 per cent. If corporations embark on the work with the intention of working on a less margin of profit they are mortgaging their other assets for at least the difference.

It will be noticed that this 9 per cent. amounts in the aggregate to very nearly as much as the total working costs, and it is a point worth carefully noting as a feature of this class of work, that subject to a certain amount of variation, there is a general tendency for a fair interest and depreciation on the capital involved to amount to as much or nearly so as the other total annual costs and charges.

IV.—Revenue and Selling Price.

Available output of station K.W.S.	Total costs, as above.	6 %, interest, 3 % depreciation on capital.	Total revenue.	Average selling price per unit.	Private supply, same size.
	£	£	£	d.	d.
2,500	13,100	12,600	25,700	1·10	·68
5,000	22,400	20,700	43,100	·85	·51
10,000	40,000	35,100	75,100	·67	·40
20,000	72,000	59,400	131,400	·58	·35
40,000	136,000	194,000	240,400	·50	·30

Expenditure and Revenue.

In this Table the total costs are brought forward from the last table. In the second column we have figures representing 9 per cent. on the total capitals of the different undertakings as shown in the last column of Table I. This 9 per cent. represents an average interest of 6 per cent. on the total capital shown, and 3 per cent. for depreciation, reserve and contingencies, also on the whole capital. This is rather a full allowance, but I have taken into account that stations are usually built up gradually and therefore may on an average cost somewhat more than is shown on the Tables for each size, and this allowance capitalised would also permit a somewhat larger sum being spent on the distributing systems without crippling the undertaking financially; it is also a point that expenditure on the distributing system has to a considerable extent to precede the earning of revenue, and therefore undertakings have often to carry for two or three years extra expenditure on the distributing system before they become properly remunerative.

With these figures we are in a position to set down the gross revenue which each undertaking ought to earn, and finally in the last column the average price per unit sold which should be obtained, the number of units being those given in Table II., together with the average load factor there stated.

In this last column we get the whole situation summed up, and can see what can be done by each of the different undertakings. It will be noticed that there is roughly a difference of over 50 per cent. in favour of the largest undertaking, and nearly that for the 20,000 kilowatt station, which is probably the more practical one to compare with. Although there are in the country a certain number of places which will ultimately warrant the erection of stations containing over 40,000 kilowatts, having regard to the nature of most of the industrial and more populous districts of

the country, the lecturer thinks that 20,000 to 25,000 kilowatts output is likely to be the type of station it will within the next 10 or 15 years pay best to erect, duplicating such stations with interconnecting mains in any district where more may be needed, but working these in the same district in parallel, under the same organisation, and arranging for them all to feed into the same network of distributing mains.

At present stations up to the size we are discussing can be designed and operated as one working unit comfortably, but to go much further than this becomes little more than duplication, when the advantages of using the same site are less, especially if by going six or eight miles off and building another station, most of the advantages of the larger station can be secured and a good deal of transmission be saved. Two such stations can be arranged to work in parallel by means of an interconnecting main, and can practically be operated nearly as one station. This is being done now on a large scale in the Newcastle district and in a number of places on the Continent.

Let us now consider these cost figures more in detail. They are of course average figures and not exactly the figures which would be charged to customers. From the smallest of these stations, energy for lighting would be sold in bulk at, say, 1½d. per unit, and the smaller classes of motors would be charged about the same price. Although, however, the average load factor may not be more than 26 per cent., yet most of the power work will be spread over a time represented by 35 per cent. and thus, as already mentioned, it will be possible to charge consumers of this class taking fair quantities of power and having fair load factors, lower prices than the average shown, especially if they can be reached without too great length of main. Probably in the case of the smallest size of plant we are considering such consumers might be charged about ·85d. per unit to ·9d. while still producing the financial results set out in the Table. If a smaller interest on the capital is taken and preliminary expenses are less, some further reduction in the charges can be made, and this is being very generally done at present in stations started on the scale but built under the expectation of ultimately attaining a much larger load. Still the general result is to confirm the opinion that a station of 2,500 kilowatts is small for giving power supply in a district where the average private plants are of considerable size. Adopting the same reasoning as above in the case of the 5,000, 10,000 and 20,000 plants, it will be seen what a very great advantage they have in these respects.

For energy taken during long hours it will be readily apparent from the Tables how much cheaper this can be supplied while still earning the same rate of profit. The capital charges to commence with are not increased but can be spread over say three times the number of units sold, the same applies to administration, rates and taxes, and labour, only additional stoking being required in a station which must under any circumstances be kept in operation continuously. The coal is increased, but as there are no more stand-by losses, about twice the quantity of coal will suffice to generate three times the number of units; roughly speaking, therefore, for nearly continuous loads, such as pumping, half the prices shown in the Tables will be remunerative.

Again, if the point of supply is near to a single consumer for a large quantity so that administrative and distribution and capital costs are reduced to a minimum, while the maximum efficiency in generation is secured, inspection of these Tables, and making the proper allowances will show how from large plants current for electrolytic and similar purposes can be profitably furnished in suitable localities for a price of as little as ·2d. per unit, and for even less, as was mentioned before.

Comparative Costs of Private Supply.

Not, however, to press the matter so far, let us use these Tables to ascertain the cost of private supply to a large manufacturer who chose to erect his own plant. Taking the smallest size of station in the Table the capital cost will be but little more than for the plant alone. Administration and labour will be reduced to about half the sum in the Tables. Coal will be say 10 per cent. less, rates and taxes, &c., will probably not be more than half. Repairs will be about three-fourths the sum allowed in the Table. If we leave the rate of interest and depreciation the same, which is in favour of the private supply, it will be found that for an average load factor of 26 per cent. the cost will come out at about ·68d. per unit, instead of 1·1d., and this agrees with published results for modern plants. Manufacturers frequently state that they are getting better results than this, but if they fairly debit themselves with the items

they ought to, these results will be found very near the truth.

It is also true that in cases where the conditions are more favourable than has been assumed in the Table, power can be supplied at some average price between those mentioned above for private supply and those given in the Tables for public supply. It is also worth noting that the cost of private supply is about that from a public station four times the size with distributing system and separate administration.

In the paper read by Mr. F. C. Snell on this subject last session before the Institution of Electrical Engineeers, the result for two plants of about 1,000 horse-power each which had been taken over for some time was given, in the first case where the plant was an up-to-date one in all respects, the costs came to ·71d. per unit and in the second case where the plant was not so well-designed the costs were ·97d. per unit. In neither of these two cases were the plants probably debited with the full amounts for rates and taxes and administration (which in equity should have been done) and in the first case the plant being a new one the repairs would be less than the average; if we make a little allowance in these respects it will be closely correct to say that a private plant of about 1,000 horse-power can, with coal at a favourable price, generate energy for itself for about ·75d. per unit at a load factor of 25 per cent. and proportionally cheaper for higher load factors. For plants of smaller size the costs must necessarily be higher. If now we look at the prices for central supply as given in the Tables, it will be seen that a station of 10,000 kilowatt size can very well compete on a bare cost basis for supply for such plants and of course with a better margin for everything of less size; as a matter of fact in nearly all industrial districts the average horse-power for industrial works will be far below 1,000 horse-power.

General Considerations.

Enough has now been said to enable anyone interested to form an intelligent conception of this portion of the subject and to show how the general figures given may be applied with the requisite modification to fit particular cases.

The subject is of the more importance because although we have considered it from the point of view of power supply chiefly, as in fact it has been considered and dealt with by Parliament, yet now power supply is intimately connected with lighting supply also, since it is found that working with large plants at high pressures for transmission it is quite practicable to supply good lighting and also heating from the power supply mains, and one source of supply should be used for all these purposes. At present in many cases power supply is being given from small lighting stations and the lighting is being made to bear the overhead and other costs to an undue extent, but later on if power and light supply can be consolidated properly the one should greatly help the other, and energy could be supplied for lighting and for heating from the joint mains at much lower prices than if the two supplies are separated.

Finally, in case objection should be taken to the capital cost allowed for the distributing system, I would point out that if the price of energy is increased 10 per cent. on the 40,000 kilowatt station, about £8 more per kilowatt could be spent on the distributing system, or 80 per cent. more than is allowed in the Tables.

Looking at these Tables as a whole it will be seen what an important part is played by interest and depreciation on the capital expenditure. If all undertakings were worked on their own bases throughout the country there would be nothing more to be said, but where as in so many cases we have portions of districts supplied by local authorities, the position becomes complicated. For instance, if local authorities borrow money at 3½ per cent. and their sinking fund is 3 per cent. and they do not otherwise allow for depreciation, this with the reduced Parliamentary expenses they will probably incur will enable the interest charges to be cut down below those adopted in the Table and a corresponding reduction of price to be made for the energy sold. No doubt when power supply in the industrial districts gets established on a firm basis and the outlook is secure, companies established for the purpose of giving such supplies will be able to obtain money at lower rates than those indicated, while local authorities having to spend more and more money if the power supply in their districts is developed will have difficulty in raising it so cheaply; but at present it must be acknowledged that the financial position has a strong tendency to lead to the undue development of small undertakings, while correspondingly hampering the laying out of the work on lines which are in themselves the most economical.

We will now pass on to the engineering aspects of our subject.

The Modern Electric Power Station.
Location of Stations.

When the source from which the electric energy is to be generated is coal, it is desirable that the station should be located in a position in which the best facilities exist for coal delivery, but in doing this it is to be remembered that delivery of coal by rail to a given point is usually cheaper than transmission of energy by cable in the United Kingdom, so that there is seldom a gain to be made by securing a shorter rail transit at the expense of correspondingly longer cable transmission. This is one reason why so far we have seen little of long distance transmission in this country. Again, when the power station is situated in a coalfield, the idea of locating the station at the pit's mouth is one which is not found of value in practice. Power stations only use one sort of coal, a cheap class of small size, and it is seldom that one colliery can produce all that is required of this particular kind, and if so the colliery owners will regulate their price by the cost of delivery of the same class of coal from other mines to the power station, and accordingly the station should be located in a position where it can easily command a supply from a number of competing collieries.

The next point to be considered, with the type of stations which are being erected now and which usually employ steam turbines, is the question of water facilities for condensation.

Condensing Water.

With marine engines the general rule was formerly that the condensers required about 35 times the amount of water to flow through them which was condensed from the steam used by the engines; with turbines, however, since higher vacua can advantageously be used demanding lower temperature cooling water, it is desirable to arrange for from 50 to 70 times the flow if possible, so that the question of water supply becomes of great importance especially if the station is of large size, and it may pay to go some distance from the centre of the district to be supplied to secure adequate water facilities. On the above basis a 10,000 kilowatt station will require about 1,000,000 gallons of water to pass through the condensers for each hour's work at full load. Not unfrequently in inland stations these facilities are impossible of attainment, and then recourse must be had to cooling towers, which are so arranged that the warm condensing water trickles down in tiny streams over wood slats arranged in tiers in a large casing forming a chimney, large volumes of air being drawn through this by natural or artificial draft. The evaporation ensuing rapidly cools the condensing water which by this means can be used over and over again, the loss by evaporation being about three-fourths of the weight of steam condensed. Cooling towers are also very valuable for partly dealing with the water when a certain amount of change can be arranged. The construction of these towers and of condensing apparatus has been greatly improved and cheapened during the last few years, so that the loss in efficiency by not having the large supply of water needed in the form of a river is not so great as it was even three or four years ago. It is also a point to be borne in mind that should gas-engines come to be employed in the future the need of such large water facilities will be diminished; thus, although water facilities still remain a very important item, too much should not be sacrificed for them. For instance, in the contests which have gone on during the last four years over the electric supply of London it has always been the writer's opinion that too much has been made of the importance of water facilities as such, especially having regard to probable improvements in generating electricity in the future.

The Departments of Power Stations.

The power station itself is naturally divided into four well marked divisions. First, the coal handling and sorting plant; next, the boilers or steam-raising division; then comes the steam utilization and electric generating division; and, lastly, we have the very important and somewhat complicated electric control department, comprising the switches, measuring, indicating and recording instruments with the means of control necessary for the proper working of the whole installation.

We will deal with each of these divisions briefly in the order mentioned, first with the coal. There is no division of central station work in which greater progress has been made than this during the last few years. In all well conducted large stations coal is now constantly tested for its calorific value, smoke, moisture, and amount of ash, and should be bought subject generally to these tests with fair variation allowances. There is a constantly growing tendency to look into these points more closely as they are found of importance in securing the

best and most constant results and in keeping a check on the stoking.

Coal and Coal Conveyors.

The treatment of coal has also of late years undergone much modification; nearly all coal now is screened at the collieries, the poorer qualities washed, and the whole graded into sizes. Formerly the general rule was that the larger the lumps of coal the higher its value, but now evenness of size is of the utmost importance, whilst dust is detrimental. The classes of coal most commonly used now in power houses vary in size from that of a pea to that of a walnut, and a good deal of larger coal at the collieries is now broken down from large lumps to these sizes, so great is the demand. Thus coal is dealt with as though it were a viscous liquid rather than a solid, and the methods of handling it are based on this assumption. On arrival at the power station it is either tipped out of the waggons into a hopper, or if delivered by boat is lifted into the hopper by grabs or other suitable means. In either case it is automatically weighed, usually by a self-registering arrangement which prints the weights. It is then carried by conveyors, usually consisting of shallow buckets arranged in a double chain, either to the reserve heap, or to bunkers situated over the boilers, which are usually of sufficient capacity for several days supply to the station; a point which must be watched being that the coal should not heat in these. Much ingenuity has been expended in working out the details of these lifting appliances and conveyors so that about three men can control the unloading and storing of 50 to 100 tons of coal per hour if necessary.

From the bunkers the coal descends to the boilers by shoots under control of the fireman, and it is usually again weighed here so that a record is kept of the amount of coal going to each boiler.

Boiler Water.

In ordinary private steam installations one of the chief difficulties nearly always arises from the water supply, owing to deposit in the boilers and the resulting loss of efficiency and cost of cleaning and repairs. In the modern central station these drawbacks have almost vanished with surface condensing, particularly if steam turbines are used, as then the condensed steam is returned to the boiler as clean distilled water and the loss can be kept well below 5 per cent. for each evaporation. The amount of fresh water to make up is, therefore, relatively small, and it usually pays to use the local water company's water for this; this water, moreover, is further treated for the expulsion of lime, and neutralisation of any alkali or acid. Methods of treating water have also been much improved of late, and in a large station the water will be tested at least every day to see that the treating process is fulfilling its work properly. This water after being treated is usually also passed through an economiser where it is heated above boiling point, which again helps to deposit any lime in a soft form easily dealt with before the water reaches the boiler. As a result of all these precautions, deposits in boilers such as were generally common have become things of the past, and boilers often now run for months without being opened up, and then are found to need scarcely anything doing inside. Thus the conditions under which steam is raised have been greatly altered, most of the old troubles which principally occupied engineers have disappeared, though with the higher standard of efficiency aimed at numerous other points now require careful attention which formerly were almost entirely neglected. It has often occurred to the lecturer that we may be now coming to a time when it would pay to use condensers for purifying the feed water as in marine work; namely, cascade condensers, which can now be obtained to distil as much as 50 lbs. of water per pound of coal, and thus ensure an absolutely pure water supply free from salts in solution which cannot be got rid of by treating, and which are apt to pit the boiler tubes.

Boiler Pumps.

A weak point in power station arrangements has always been the boiler pumps, which even with the best designs take an inordinate amount of steam for the work they do. Electrically driven pumps taking their supply from the station omnibus bars are in use to some extent, but it has been difficult to get anything so far which will conveniently and satisfactorily perform the very heavy duty expected from a boiler pump, which has to work against a constant head for the whole stroke, and has to do this over a very wide range of speeds. The new Rees Roturbo pump is now being coupled to an electric motor and applied to this work, and if it succeeds permanently it will have removed a source of undue loss. Although, however, boiler pumps may be inefficient apparatus in

power stations, they are still more so in private plants; and, when, as is frequently the case, cheap pumps are used and not well looked after, it is a common thing in such plants for the pumps to take over 100lbs. steam per horse-power hour, and in small installations they may even quite seriously reduce the overall efficiency of the plant. Theoretically, each pump should take about three per cent. of the power in the steam generated; but twice this figure would be a moderate amount to allow in most central stations—six per cent. Neglect of the pumps may greatly increase even these allowances.

THE MINING INDUSTRIES OF BOLIVIA.

Bolivian purchases of mining machinery depend on the development of the tin, silver, copper, and gold mines. The introduction of modern machinery is likely to be the result of the railway building which is now going on, since this will reduce the expenses of transportation, and render accessible regions that heretofore have worked the mines after the old methods and with limited means, on account of the very heavy charges incurred in carrying the products of the mines. According to the United States Special Agent in Bolivia, the tin mines are likely to furnish the best market. The Bolivian production in 1907 was approximately 16,000 tons of pure tin, slightly less than for the previous year. Substantially all the shipments are in the form of barilla or concentrates: These are calculated on the basis of an average of 60 per cent. of pure metal in the ton of concentrates, and the Government export tax is levied on that basis. The average price for 1907 was £97 for the concentrates, and £173 for the metal. When the price rose to £200 per ton, all the Bolivian mines were active, and many new ones were opened up, in the expectation that the boom would continue. The drop in the price of the metal naturally caused most of the new enterprises to be suspended, while a large number of the small mines also shut down temporarily. These were mines employing 80 to 100 workmen, and possessing only the crudest facilities. The majority of the larger mines were able to keep going. When it is recalled that in 1900 Bolivia was producing only 6,000 tons of tin as against 16,000 in 1907, some idea may be obtained of the future development and the market for machinery that will be opened up. The bulk of the output is in the departments of Oruro and Potosi, all of which is carried on the railway to Autofogasta on the coast. The Huayani-Potosi, and the Milluni and other mines in the La Paz district have about 8 per cent. of the production, which is shipped by Lake Titicaca and Mollendo. A few of the richest mines, notably those in the neighbourhood of Oruro, where the tin exists in combination with silver, employ a crude smelting process and are able to ship the tin in bars, but generally the very high cost of fuel and other conditions make the shipment of the concentrates cheaper than the smelting of the ore, so that manufacturers can depend on the demand in the future being along the same lines as at present. Up to this time most of the stamps and tables for the concentrators and other machinery have been imported from Europe, one reason for this being perhaps that until quite recently there have been no American interests in Bolivia. The ownership of the tin mines is English, Chilean, and German, and the purchases have been largely made through London and Hamburg. Germany has sold large quantities of mining machinery because it had control of Bolivian commerce in all lines. These sales were not due to superior quality or to cheapness. It is almost the universal testimony that German installations for the tin mines have been unsatisfactory. It has been stated by a large mine owner that he would like to throw out the German installation entirely, but that neither he nor other mine owners could afford to "scrap" their machinery by wholesale, and they would have to continue working along, and gradually replace the German machines with those from America, as their initial purchases in the United States had been satisfactory. Preference, however, is shown for the English make, as being more solid. There is, it is said, the possibility of a severe competition between England, the United States, and Germany, the German agents promising to supply better material, such as that from the Krupp works at Essen. The works at Creusot, France, also have local representatives, but they are not represented by actual installations in many of the mines. In the laboratories for metallurgical work the chemists and mining engineers give the preference to France, one reason being, it is stated, that the French packing is almost perfect. Laboratory supplies from the United States usually come broken in pieces. During the last two years various mining experts from the United States have made investigations of the Bolivian tin deposits, and of the mines in operation. It is well understood that the tin plate interests of Pittsburg and elsewhere would like to secure control of the output of some of the leading mines, but nothing seems to have been accomplished in this direction yet. Other American interests, some of them with rather limited capital, have undertaken the development of tin mines on their own account. The American capitalists, who are building the Bolivian railways, have also mining concessions, but it is not understood to be their intention to have the railway company engage in tin mining, or other mining. It is more than likely that some of them will invest in the mining business as individuals, while the policy of the railway company will be also to encourage other companies or individuals to engage in mining in order to supply the railway with articles for transport. Out of this policy there is likely to grow a number of

American mining interests, which will buy machinery in the United States, provided the objections as to bad packing are removed. It may be taken as certain, says the United States Special Agent, that Bolivian tin mines, during the next few years, are going to be developed on a scale which will call for large quantities of machinery. The increase in silver mining is dependent on the railway line from Oruro to Potosi, which now seems assured, since the American and the English interests are harmonising their differences. Potosi is the most extensive silver mining region of Bolivia, but the lack of transportation facilities has made it impossible to introduce new machinery, and without this, and the application of modern processes, it has been shown that the Potosi mines, with some exceptions, cannot be worked so satisfactorily as is desired. The Huanchaca mines, near Uyuni, which, for many years, were among the most profitable in South America, are in full operation, and are supplied with modern machinery. The output of the Corocoro copper mines is not expected to be seriously diminished on account of the fall in the price of that metal, since most of those in operation were able to continue in spite of the depression. New development, however, was checked. The Corocoro fields are agreed by experts to be very rich, but their development on a large scale has not been attempted heretofore, because the efforts to combine them have failed. Promoters from the United States, at various times, have obtained options on these mines, but have not secured the capital necessary to take up the options. The capitalists in the United States, whom they have approached, have invariably declared the price too high. It is possible, however, that in time the negotiations will succeed, and the exploitation of the Corocoro copper will be undertaken on a large scale, ensuring heavy purchases of machinery. At present the disposition appears to be to await the building of the railway line from Arica, which will ensure a short railway route to the coast, and effect an important saving in the cost of transport. There does not appear to be much prospect of immediate sales of dredging machinery for Bolivian gold mines. Several years ago dredges were installed in the San Juan river-bed in the south. The cost of the installation was very high, since the machinery had to be carried by mules for two hundred miles over difficult mountain passes. Now the railway, which extends from Buenos Aires to the Bolivian border, removes this difficulty, but the dredging itself has not been successful enough to encourage further importations of machinery. In the Tipuani river, in northern Bolivia, gold is abundant, but the transportation of dredging machinery is entirely impracticable, and the Tipuani is likely to be left to the primitive methods of placer mining. A point which should have attention in connection with mining machinery is the large quantity of explosives consumed in Bolivia. These are procured almost entirely from Europe, Germany having the lead. It is said that the bad name given to American manufacturers of explosives by the action of one company, which some years ago dumped a lot of inferior dynamite on the South American market, has not yet been overcome. In conclusion, the Special Agent says that Bolivian mining resources, both from the point of view of the manufacturers of machinery and from that of capitalists, are worthy of the most careful investigation, for the country is one of the world's greatest mineral regions. Until railway communication could be obtained, many of the districts, notwithstanding the richness of their deposits, could not be expected to command capital, because of the prohibitive cost of transportation, both for machinery and for ores. That difficulty is now being removed, and with the extension of the railway system a continuous mining development may be looked for.

THE UTILISATION OF EUCALYPTUS LEAVES.

There are many places in Australia where eucalyptus oil is distiilled for medicinal purposes, and there is said to be an establishment in New South Wales where acetic acid is an important by-product in the distillation of the oil. It is, however, at Fort Esperance—about fifty miles distant by water from Hobart—that the eucalyptus oil itself is considered merely a by-product in the preparation of the more valuable extract for use in preventing deterioration of boilers. This extract has the appearance and consistency of tar when prepared for export to England. It is shipped with no more liquid in it than is necessary to prevent caking in the casks *en route*, it being thinned, however, on its arrival. The extract is said to diffuse itself through the water of boilers and cleanse them of any acid, greasy or saline matter, forming with such deleterious ingredients a harmless sediment which sinks to the bottom, and it prevents any formation of crust round the water-line. The American Consul at Hobart says that four tons of eucalyptus leaves will produce one ton of the extract for boilers, and about seventy or eighty pounds of eucalyptus oil. Twigs of the leaves are taken off the trees irrespective of the age or height of the tree, except that old trees are not preferred owing to the great preponderance of woody matter. They are placed in large bags, and, by an iron hook arrangement, are carried down the hill-side along wires specially strung for their easy transportation to the mill. The leaves are for the most part about ten inches long, and from an inch to an inch and a half wide. The leaves mostly used at the establishment referred to above are taken from an underbrush of trees in "bush" destroyed by fire about two years ago. The same trees may be considered good for another crop of satisfactory leaves in about three years after the first leaves have gone to the mill. The leaves are placed in a large cauldron, called a digester, and steam is applied for four hours. During this steaming the acetic acid in the leaves passes out as

vapour, the eucalyptus oil is carried by the steam to the condenser, the waste water being separated by the use of a syphon. The residuum in the digester is then subjected to steam pressure, by means of which the valuable extract is obtained, being first, however, boiled down to the consistency of tar. The woody matter which is left in the digester after the oil and extract have been taken out is then removed, and burned as refuse. In order to prevent the digesters being eaten by the action of the acetic acid in the leaves, they are painted with the extract before the leaves are put in and the steam applied. Some experiments have recently been made at Port Esperance to ascertain if varieties of eucalyptus leaves, other than the blue gums, could be used for the production of both boiler extract and eucalyptus oil, and as a result it appears that practically every variety of eucalyptus leaf will furnish the boiler extract, but that the best quality of eucalyptus oil by-product is obtained from the blue gum. The stringy bark contains more of the extract, but less of the oil than the blue gum. The local consumption of eucalyptus oil for medicinal purposes is very large. There are other uses to which, it is said, eucalyptus can be put, although there has, as yet, been no practical demonstration of such uses in Tasmania. An illuminant, known as "gum gas," can be produced from the leaves, and is said to give a bright light. An Australian authority has estimated that 10,000 feet of gas can be obtained from a ton of leaves. The eucalyptus bark is said to contain a fibre suitable for paper, and eucalyptus woods are considered valuable for many purposes.

HOME INDUSTRIES.

The Coal Trade.—Although the labour troubles in South Wales have been settled for the time being, the dispute between masters and men in Scotland has become more acute. A week ago the Scottish coal masters decided to post notices of a reduction of wages on the 26th inst. This decision followed on an abortive conference. The proposed reduction of wages is 12½ per cent. on the standard and would amount to about 6d. per day per man. It is induced by the Eight Hours' Act, which reduces the number of hours the men are at work. The employers insist that if the hours are to be shorter the pay must be less. On the other hand the men look upon the Act as one intended to benefit them, whereas if their wages are to be reduced at the same time that the hours of labour are shortened they will consider it as of very doubtful advantage to themselves. The Scottish trade holidays are now in full swing, and iron furnaces have been damped accordingly. It may be hoped that some arrangement will be arrived at even now, and it must be remembered that the men are financially in a very weak position. The numbers affected by the lock-out would be something like 100,000, 80,000 miners and 20,000 pit-workers, but the men's accumulated funds only amount to £70,000, which would mean bankruptcy for their union in a fortnight unless the Welsh and English miners made a substantial levy. The danger of serious complications lies here. It is not at all unlikely that the English and Welsh miners will decide to range themselves along side the Scotch miners, in which case the whole situation will be changed.

Pit Lads.—In Staffordshire 7,000 pit boys are on strike, and there has been rather serious rioting. All the important pits in North Staffordshire are now idle, and an industry which employs 25,000 men, and yields a product of some 7,000,000 tons of coal annually, is paralysed. As a consequence of the dispute some of the forges and furnaces in the steel industry in the district have already been damped down, owing partly to the shortage of coal, and partly to the fear that damage may be done to the plant. Here again the trade disturbance is due to the Miners' Eight Hours Act. The ostensible cause of the trouble is the question of a stoppage for a meal, or for "snapping," as it is called. Immediately upon the Act coming into force (July 1st) difficulties arose. The miners contend that under it, as interpreted by the masters, their conditions of work have become worse. They say it entails longer hours instead of shorter. Before the Act came into force the men in this district did not put in a full eight hours of actual work in the pit. The masters now seek to enforce a full eight hours of work. This, with the time spent in "winding" and in getting to work, entails sometimes, the men say, as much as ten hours from bank to bank. The masters, too, require a full eight hours without "snapping" time. Previously the men had half an hour allowed them for eating, but the dispute as between masters and men on this particular point has been settled by compromise, the masters agreeing to allow a quarter of an hour instead of half an hour as aforetime. It is against this agreement that the lads have risen, since under it many of them, as they say, get no "snapping" time at all. They must keep on working. The agreement between masters and men stipulates that the men must take their snapping time not altogether as they used to do (the pit being "stopped" for the purpose) but in two separate lots. The long wall system is generally used in North Staffordshire, and the arrangement was that while the men on the one "side" had their "snapping" the men on the other "side" should be at work, the object being to prevent any stopping of the pit during the eight hours. Unfortunately this arrangement means that the lads working in the roads between the men have to keep on the eight hours without a break. Hence the strike.

The Co-Partnery Mining Project.—Many will regret the failure of Sir Christopher Furness's co-partnery project referred to in these Notes some weeks ago. It has failed because the men have rejected it.

Sir Christopher Furness, in his reply to the leaders of the Wingate Grange Colliery workmen, says that "he is afraid that the resolution of advice to the men was influenced by bias, personal as well as political, affecting the county, and in fact the country at large, rather then by reasons purely economic and applying to the employees at Wingate alone." However that may be, the men seem to have been influenced by the fear that the proposed colliery council would become a "hot bed of spies," and also that only the first-class workmen would be employed. There does not seem to have been any attempt on the part of the representatives of the men to smooth over difficulties by consultation with Sir Christopher Furness, but he is willing to revive the project if, and when, the men are prepared to consider it more favourably.

Gas Engines for Steel Works.—The *Manchester Guardian* gives some particulars as to the equipment of two important steel works—those of the Barrow Hematite Steel Company, Limited, and the Frodingham Iron and Steel Company—with blast furnace gas-engine plant of German design and manufacture. In the former case, it is claimed that a saving of £1,000 a week has been effected by the German gas engines put in to utilise the waste gases from the furnaces. At the Staffordshire Steel Works, Bilston, a new electrical and power plant has been installed by British engineers, and in reply to some disparaging comparison made between this and the German plants, Sir Alfred Hickman has written a letter to the *Iron and Steel Times*, in which he says:—"It is true that some difficulties, not unusual in a new departure, have been experienced, but if I am correctly informed, they are far less than have attended a somewhat similar installation by a German firm at works in the North, the engineering staff of which have honoured me by repeated visits in order to obtain information and assistance. The arrangements here are not yet perfected, but there has been no shirking of responsibility on the part of the contractors, and I have every confidence that in the end the work will be fully equal, if not superior, to anything the Germans have done, and the cost will certainly not be greater than they would have charged."

Hop Substitutes.—It is not, perhaps, surprising that the Government Bill to prohibit the use of hop substitutes in brewing, and the importation of hops except in bags properly marked, should be described by political opponents as protection, "unadulterated, naked Protection," as Lord Courtenay put it in the debate in the House of Lords upon the second reading. The object of the Bill is to prohibit the use of preservatives when the necessary preservation can be obtained by the use of hops alone. This is not an absolute prohibition of preservatives, since to do away with them altogether might mean the destruction of a great trade in a certain class of beer intended for export, but if the Bill becomes law it will no longer be possible to use them in beers intended for home consumption. As to marking, the intention is to place the foreign and home hop growers on an equal footing. Lord Carrington described the Bill as "an honest attempt to assist a hard-working and honourable class of people who have been passing through a time of much difficulty." The object is excellent, but it is to be feared that even if the Bill becomes law it will not arrest the shrinkage in the area of hop cultivation which has been going on for many years past, and of late at a much accelerated pace.

American Wheat Prospects.—Although our imports of wheat from America are comparatively much less important than they were ten or fifteen years ago, they are still a very important factor in the movement of prices, and it is therefore satisfactory to find that on the whole the prospects of the present American crops are encouraging. According to the Government crop report the condition of winter wheat on July 1 was 82·4, in comparison with 80·6 on the corresponding date of last year, and a 10-year average of 79·6. Unfortunately the acreage under cultivation is 8·1 per cent. less than the wheat area harvested last year, the acreage this year being 27,871,000. It is estimated that the winter wheat crop will be about 410,000,000 bushels, as against 480,000,000 bushels in 1908, and 409,000,000 in 1907. But the spring wheat crop promises to more than adjust the balance. The acrerage under spring wheat is nearly 7 per cent. more than last year, and the condition of the crop on July 1 was 92·7 as against 89·4 in 1908, and a 10-year average of 87. The yield is expected to be about 254,000,000 bushels, in comparison with a crop last year of 226,000,000 bushels. Taking spring and winter wheat together the present estimate is about 663,000,000 bushels this year, which does not differ materially from that of last year. This is better than was anticipated at one time, but bearing in mind the constant growth of the American home demand it is obvious that the United States will not do much this year towards bringing down prices to meet the level of the last 10-year average.

Trade Unions and Labour Exchanges.—Representatives of the Trade Unions met the President of the Board of Trade last Friday to discuss the subject of labour exchanges. They suggested regulations which would bring into the committees in whose hands the local control of the exchanges will be representatives of employers and workmen in equal proportions. An important condition asked for was that exchanges shall not be used for the purpose of facilitating attempts by employers to break down a strike or carry on a lock-out, and the delegates wished to be assured that they would not aid in reducing the standard of wages or other labour conditions in the localities in which they operate. On many points the President of the Board of Trade was in agreement with the deputation, and promised to incorporate

their proposals in the regulations when they are made. None of the regulations have yet been framed, the Government wishing to have the views of all interested before framing them. It is expected that the regulations will be issued in the autumn, although it is not likely that any new exchanges will actually be at work before the new year.

CORRESPONDENCE.

CANADA AS A FIELD FOR BRITISH INVESTMENT AND SETTLEMENT.

Mr. J. Obed Smith, in his paper on Canada, published in your *Journal* of June 11, gives as a quotation from Chisholm's "Commercial Geography" a sentence that he seems to have read rather hurriedly. He says, "Professor Chisholm, in the third edition of 'Commercial Geography,' says:—'If British commerce has in recent years advanced with less strides than that of some other countries, geographical ignorance on the part of merchants and business men can be set down as one of the principal causes.'" The sentence, which occurs in the preface to the first edition of the "Commercial Geography," and is reprinted in the third edition, reads as follows:—"From my inquiries on the subject of commercial geography I certainly have not derived the impression that, if British commerce has in recent years advanced with less rapid strides than that of some other countries, geographical ignorance on the part of the British merchant can be set down as one of the principal causes."

A slip of this kind may be of little consequence, but, thinking that you, in justice to both Mr. Chisholm and the British merchant, might wish to correct it, I am taking the liberty of drawing your attention to it. ROBERT BAPTIE.

Seattle, Washington, U.S.A.,
June 29, 1909.

I have perused with much interest the extremely able paper read at a recent meeting of your Society by Mr. Obed Smith. There were two matters, however, which were not emphasised, and which I venture to suggest should receive consideration.

The first is the large field for investment in the debentures and shares of some of the smaller companies which present absolute security and offer a profitable return. I have come across a number of manufacturing concerns which are doing a good business, but which, if they had a little more capital, could double or treble their present turnover. This is especially so in Ontario, which is the manufacturing province of the Dominion. Mr. Smith referred naturally to the more important avenues for investment, but these require considerable capital, and the smaller capitalist and investor at home may not feel he can join in these large ventures, whereas there are numerous opportunities for the investment of sums of £500 and upwards in good, sound companies where substantial dividends can be earned. Further, in the case of a young man desiring to engage in commercial life here, if he can bring with him say £1,000, which can be invested in a good going concern, he can very shortly step into a position which he would not reach otherwise in connection with that business, provided, of course, he possesses the ability.

The second point is that if British capital is to find its way here for these smaller businesses, some one on this side should be employed, first to investigate the business and go over its books, then report to the investor at home, and afterwards represent such investor on the Board of the company. I could put my hand on a number of excellent businesses needing capital, where such an arrangement could be offered, and doubtless there are many others in a similar position to myself. ERNEST H. SCAMMELL.

40, Lombard-street, Toronto.

OBITUARY.

THE MARQUIS OF RIPON, K.G., G.C.S.I., C.I.E., D.C.L., F.R.S.—The Marquis of Ripon, who died at Studley Royal on the 9th inst., was one of the oldest members of the Society, which he joined in the year 1856. He never took any active part in the Society's work—on one occasion he presided at a meeting of the Indian Section in 1890, when Sir Theodore Hope read a paper on Indian Railways—but he supported the Society liberally, as for over 50 years he paid a subscription of Five Guineas per annum instead of the ordinary subscription of £2 2s.

Lord Ripon was a son of Viscount Goderich, who held office for a short time as Prime Minister, and became Earl of Ripon in 1833. He was born in 1827 and succeeded his father in 1859. After a short diplomatic experience he became, in 1853, a member of the House of Commons. Soon after his removal to the Upper House in succession to his father, he took office as Under-Secretary for War, and this was the first of numerous posts held by him in successive Liberal Governments. He was created Marquis of Ripon in 1871. In 1874 he became a Roman Catholic, and this, according to the obituary notice in *The Times*, involved his withdrawal from public life for several years. In 1880 he became Viceroy of India and held the office till 1884. He again held cabinet office after his return from India, his last post being that of Lord Privy Seal, in which office he acted as the leader of the Liberal party in the Upper House. In 1908 he resigned, nominally on the plea of failing health, but really it is said in consequence of the Government's interference with a proposed Catholic procession in Westminster.

NOTES ON BOOKS.

THE CAMPAIGN AGAINST MICROBES. By Étienne Burnet, M.D. Translated from the French by E. E. Austen. London: John Bale, Sons and Danielsson, Ltd.

This book is a translation of a number of articles by Dr. Burnet on cancer, tuberculosis, tetanus, sleeping sickness, enteritis, and smallpox. In a non-medical journal it will not be expected that any opinion should be given upon the views expressed in such a book, or even of the correctness of the statements or opinions. But it may at all events be said that a very clear popular account is given of the action of microbes in producing the various diseases dealt with, and in the treatment suggested for their alleviation. The subject is by no means exhausted, as, though the title is somewhat comprehensive, the subject-matter does not extend beyond the special diseases mentioned. The researches detailed appear to be mainly the work of others than the writer, for instance, the chapter on enteritis is mainly an account of Metchnikoff's work, which has been already introduced to non-medical readers by Dr. Chalmers Mitchell's translations of his well-known works, while the chapter on variola and vaccinia is a very interesting account of Jenner's work, and of the practice of inoculation which preceded Jenner's researches.

RELICS OF THE HONOURABLE EAST INDIA COMPANY. London: Bernard Quaritch. 1909.

In the year 1890 a report by Sir George Birdwood on the miscellaneous old records at the India Office was published by that office, and in the same year a paper was read before the Society of Arts on the subject by the late Mr. F. C. Danvers, who was at that time Registrar and Superintendent of Records at the India Office. The interest aroused by Mr. Danvers' paper induced Mr. Griggs to publish in his *Journal of Indian Art* some photographic reproductions of the more important charters and despatches of the Company. These pictures have now been reproduced in a sumptuous volume under the above title, and the reproductions have had the advantage of descriptions by Sir George Birdwood and Mr. William Foster, together with an introduction by Sir George Birdwood.

The reproductions, a number of which are in colour, include the arms of the first Company, several of the charters, warrants, and patents issued to the Company, and various other documents of great interest. There are also pictures of the various buildings occupied by the Company at different times, all of which were known in succession as "The East India House." Then there are some photographs of the interior and exterior of the India Office, and various other pictures of objects of interest in the history of the Company.

Sir George Birdwood's introduction gives a brief record of the foundation and early history of the Company, or rather companies, since the one first incorporated by Queen Elizabeth in 1600, and known as the Old Company, changed its character and status by the amalgamation with it of several other companies subsequently incorporated, so that the body known to us as the Honourable East India Company, which lasted down to 1858, may be said to date from a charter of Queen Anne of 1709. The letter-press which accompanies the reproductions is certainly not less interesting than the reproductions themselves, and the whole volume is full of information relating not only to the East India Company, but also to what Sir George Birdwood called in his Report of twenty years ago, "the modern quest and invention of the Indies."

It may be worth while to point out a trifling mistake in one place. George Lambert, the painter of the pictures now in the Military Committee Room at the India Office, was never a President of the Society of Arts. The institution with which he was associated was one of the two Societies of Artists, which grew out of the "Exhibition of Polite Arts" held in 1760 by the Society of Arts, and the rivalry between which led eventually to the foundation of the Royal Academy in 1768.

GENERAL NOTES.

THE ZIMBABWE RUINS.—Mr. Richard N. Hall, who gave the Society a paper on the Zimbabwe (Rhodesia) ruins in 1905, is about to publish a book on "Pre-Historic Rhodesia." The work is a reply to the conclusions of Dr. Randall MacIver as to the origin and age of the wonderful stone buildings and gold mines scattered over Rhodesia and South-Eastern Africa. Before the meeting of the British Association in South Africa in 1905, Professor Randall MacIver made an examination of Zimbabwe, and during his researches and excavations discovered specimens of Nankin china under some of the walls supposed to be ancient. This fact, and other indications, led him to adopt the conclusion that the buildings were not the work of a non-African, possibly Semitic, race of invaders and gold-seekers at a period of (say) 2,000 years ago, but were an independent development of indigenous Bantu civilisation and perhaps contemporaneous with the coming of the Islamic Arabs and the Portuguese (from A.D. 1200 to 1600). Mr. Hall has since re-examined the Zimbabwe ruins and made other researches in South Africa, and the results of these efforts is the forthcoming volume. Mr. Fisher Unwin is the publisher.

NOTICES.

CHAIRMANSHIP OF COUNCIL.

On Monday, 19th inst., at their first meeting after the annual election, the Council re-elected Sir William White, K.C.B., F.R.S., LL.D., D.Sc., as Chairman for the ensuing year.

EXAMINATIONS.

The results of the Intermediate Examinations (Stage II.) have been published, and copies for distribution to Candidates have been sent to all Centres. The results of the Elementary Examinations (Stage I.) will be published about the middle of August. The results of the Advanced Examinations (Stage III.) were published on the 17th June.

The Council of the Society have had for some time under consideration a suggestion emanating from some of the local Committees that longer time should be allotted to the examinations than is now the case, so that greater facilities might be afforded to candidates wishing to take up several subjects in the same year.

Realising that this was a matter entirely for the convenience of the Local Committees, they caused a circular to be issued to all the Committees, asking for an expression of opinion. Replies were received from 201 out of the 392 Committees to whom the circular was sent, and the Examinations Committee, after an examination of the replies, recommended to the Council that the result of the inquiry did not appear to justify any alteration in the existing system.

This recommendation has been approved by the Council, who also approved a recommendation by the Committee that the rule requiring two Superintendents to be present at all examinations should be modified, and that in future the attendance of a single Superintendent should be considered sufficient when the number of candidates did not exceed ten.

The following is the Time Table for 1910:—

	Monday, April 11. (7—10 p.m.)	Tuesday, April 12. (7—10 p.m.)	Wednesday, April 13. (7—10 p.m.)	Thursday, April 14. (7—10 p.m.)	Friday, April 15. (7—10 p.m.)
Advanced Stage.	Book-keeping. Précis-writing. Economics. Danish and Norwegian.	Arithmetic. Commercial Law. German. Italian. Spanish.	French. Commercial History and Geography. Typewriting (7.30 to 10 p.m.).	Accounting and Banking. Shorthand (140 and 120 words per minute) (7.15 to 10 p.m.).	Portuguese. English. Russian. Swedish. Chinese. Japanese. Hindustani.
Intermediate Stage.	Typewriting (7.30 to 10 p.m.). French. Danish and Norwegian. Commercial History and Geography.	Book-keeping. Précis-writing.	English. Economics. Spanish.	Arithmetic. German. Portuguese. Italian. Russian. Chinese. Japanese. Hindustani.	Swedish. Shorthand (100 and 80 words per minute) (7.15 to 10 p.m.).
Elementary Stage.	Handwriting and Correspondence. French.	Commercial Geography. Typewriting (7.30 to 10 p.m.).	Book-keeping Spanish.	Shorthand (50 words per minute (7.15 to 10 p.m.).	German. Italian. Arithmetic.
Music.		Harmony.	Rudiments of Music (7 to 9 p.m.).		

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE PUBLIC SUPPLY OF ELECTRIC POWER.

By G. L. Addenbrooke, M.I.E.E.

PART III.*

Boilers.

We now come to the boilers. This is so large a subject that a whole course of lectures would not deal adequately with it. In the first place, water-tube boilers have become almost stereotyped as steam generators in power stations. The old doubt as to their ability to keep steam regularly has been removed by the almost universal adoption of chain grate, and overfeed, underfeed, and other forms of mechanical stoker, which enable a constant fire to be maintained. With mechanical stoking it has been possible to use larger and deeper grates than when hand-firing was employed, and this has enabled much larger boilers to be constructed than was formerly possible. A common size of water-tube boiler now is one evaporating about 16,000 lbs. of water per hour, and for large stations a standard size is made by several makers which evaporates 32,000 lbs. of water per hour, and even these figures are being exceeded. This is compared with an evaporation of 6,000 to 8,000 lbs. of water per hour, which is the usual evaporating power of the large size of Lancashire cylindrical boiler.

Boiler Arrangement.

An important point in central station design is the arrangement of the boilers. In small and moderate sized stations it is usual to place them in a parallel row with the engine room. For large stations the row becomes a double one, with the firing fronts of the boilers facing each other, leaving room for the economiser behind. For very large stations in towns it has been the practice for some time to place the boilers in two or more double tiers, though this can only be recommended when there is no other alternative. In similar stations when land is cheaper practice is now favouring the placing of the boilers at right angles to the engine or turbine room in double rows backing each other. This really changes the boiler room from a single unit into separate units for each turbine, requiring also a correspondingly increased number of chimneys. It has the advantage from the point of safety of breaking up the boiler room, but reduces its convenience and flexibility, and also somewhat increases the cost as well as that of the coal-conveying and storing arrangements.

The steam pressure most usually adopted now is 160 to 200 lbs. per square inch. With turbines the advantages of going higher are less than with steam engines, and the value of a good vacuum is greater, or rather a good vacuum is more easily made use of in the turbine than in the steam engine. Turbines also lend themselves very readily to the use of superheat. It is now the usual practice to superheat 150°, which appears to be about the desirable limit for the Parsons type of turbine. In the impulse turbine, when the clearances are greater, superheating has, however, been carried as far as 300° Fahr. with good results, and it is probable that in the future there will be an increase in this direction.

Superheating.

This superheating is usually obtained by fitting the boilers with a superheater placed just under the steam drums, and forming an integral part of the boiler. This is admittedly a compromise. An independently fired superheater allows better control of the superheat, and permits superheating to be carried further, but with coal firing it is troublesome and not always economical when the load is a varied one and there is a good deal of difficulty in finding a convenient place for it in the station. If producer gas were available in a station an independently fired superheater would have many advantages, and it might even be worth taking the steam in stages through the turbines, superheating between, or subdividing the turbine itself into two stages. In dealing with superheat, however, it is necessary to be careful to ascertain by how much the percentage gain exceeds the amount of coal used to obtain it, as it is easy to get a higher efficiency but at an increased consumption of coal which more than balances the gain. A good deal of care has also to be used to keep the superheat even and prevent excessive rises of the temperature as load decreases.

* The Course consisted of three lectures, delivered on January 18 and 25, and February 1. In re-arranging the material for publication, the lecturer has preferred to divide it into four parts.

Stoking and Working.

The almost universal adoption of mechanical stoking in modern boilers for considerable output has already been alluded to, and also the automatic delivery of the coal to the stokers. By these means the usual manual labour of the stoker is reduced to occasional clinkering, clearing away ashes and a few other odd jobs about the boiler house, but it does not follow from this that his labour is lightened; what has been taken from his hands has been placed on his head. Besides the steam, water and superheat gauges and the boiler pumps, economiser and forced or induced draught appliances, he has to watch the rate of travel of his grate or rate of working of other forms of mechanical stoker, the thickness of his fire on the grate, the amount of draught and the getting rid of the ashes, and whether the coal is fully burned out before reaching the end of its travel. All these points make great differences in the efficiency of the plant.

A boiler worked at its best can under good working conditions, such as should be obtained in a power station, transfer about 80 per cent. of the heat in the coal to the water and steam in the boiler; of the balance rather more than 10 per cent. will be lost in gases going into the flue of which a part may be recovered in the economiser, and rather less than 10 per cent. will usually disappear in radiation, say 8 per cent. or 1-12th. Now it is important to observe that the lost 8 per cent. is a loss which only slightly decreases whatever the boiler is doing, if steam is kept up under pressure, consequently at half load this 8 per cent. becomes about 15 per cent. and at quarter load 30 per cent. of the total coal, until we gradually come down to the boiler standing banked, when 6 per cent. to 7 per cent. of the coal required at full load will be required merely for the purpose of keeping steam up to pressure.

This does not represent the whole loss of efficiency as boilers are worked at lighter loads, because at lower loads it is increasingly difficult to secure just the right proportion of air, and an increasingly large proportion of heat will be carried off in this way.

Notwithstanding these losses in working at low loads and in keeping the fires banked, it is as a rule, however, found that when a boiler has to be used for only a portion of the day, it is more economical in coal to bank it than to let it down entirely and to fire up again.

Radiation Losses and Losses by Excess Air.

To give an example, assume a boiler capable of evaporating 16,000 lbs. of water per hour, a common size in power stations, this will at full load evaporate and superheat about 8 lbs. of water, equivalent to about 8¾ lbs. of saturated steam. Owing to the above reasons, however, at half-load it will not evaporate more than 6½ lbs. of water, and at ¼ load about 4 lbs. of water per pound of coal, while if it is banked and doing nothing it will consume not less than 1 cwt. of coal per hour to keep up steam pressure. Now these radiation and other losses are to a considerable extent within the control of the stoker, particularly as regards the coal used in banking and in firing up, and it is obvious that the stoker who can avoid stoking up an extra boiler to carry his heavy load will be the better man.

The stoker has, moreover, great control over the draught and over the coal burnt. If he lets too little air through his grate he will not use the full evaporating power of the boiler; if he lets in too much by having too thin a fire the cooling may reduce the evaporation 10 per cent. to 15 per cent. or more. It is again quite possible to lose several per cent. of the combustible by letting it through the ends of the grate before it is completely burnt. It will therefore be seen that in boiler-houses, to secure the best results, particularly when the load varies considerably during the twenty-four hours, much intelligence is needed in managing the boilers, and it is quite easy with the same plant to get differences of coal consumption of 20 to 30 per cent., or even more, for the same amount of water evaporated.

CO_2 Recorders.

In order to guide the stoker it has lately become the practice to instal what are called CO_2 recorders in the flue from the boilers. This apparatus draws automatically a sample of the gases passing every quarter of an hour or so, and the gas being passed through a proper piece of apparatus the carbonic acid is absorbed, increasing its weight correspondingly, which weight is automatically recorded. Knowing the proper proportion, this at once shows if too much or too little air is being admitted to the grates. This is found to call the attention of the stokers to irregularities which they would not notice otherwise, and if intelligently used it considerably promotes efficient working. Some difficulty arises if the boilers become numerous, as a single

instrument gives only a general result, but nevertheless it is a very distinct gain in station practice.

Losses in Boilers.

For the reasons which have been mentioned it is clear that the coal used per pound of steam supplied to the engines or turbines will be considerably more than if the boilers could always be maintained at their best efficiency; thus in a lighting station it is quite common that the weight of coal used per annum is three times the amount which would be used if engines and boilers could always be worked to their best efficiency. In power stations the difference is less. In a 2,000 kilowatt station working with a 25% load factor the coal used will be about 1¾ times to twice that necessary if the boilers and the engines or turbines were used to the best advantage. As the size of the station increases and the load factor improves the proportion of these losses is somewhat reduced, which is one of the reasons for concentration.

In most stations economisers are used situated in a flue behind the boilers, or above them sometimes when space is limited. Unless coal is very cheap, the extra duty obtained is well worth the additional capital cost, particularly if the station has a considerable load, as we are assuming, since with them the hotter feed enables a heavier duty to be obtained from the boilers at full load. The gain to be obtained depends on the type of boiler used, the draught, conditions of working, &c., but may be taken as in the neighbourhood of 12 per cent. on an average.

The Draught.

The cost of constructing brick chimneys has greatly lessened during the last few years, and frequently iron chimneys are now substituted for brickwork; but, notwithstanding these economies, there is a strong tendency in large stations to adopt induced or forced draught, usually the former, by the aid of a fan fixed in the flue, near the base of the chimney. There is little doubt that as the loads in power stations get heavier more and more reliance will be placed on mechanical draught, and probably on the development of this, which is obtained by using the Eaves principle of heating the air before it reaches the coal by the help of the waste flue gases.

The use of economisers, forced or induced draught, and air heating are all important factors, but their relative value depends so much on the character of the load, the classes of coal used and its price, and the balance of extra capital cost of these refinements against the economies secured, that it is difficult to put the probable advantages into exact figures. Pre-heating the air is only employed to a small extent at present, it being rather difficult to adopt unless the boiler-house and flues have been designed, in the first place, for its use, but it is safe to say that its adoption will be much extended in the future. In cases where it has been used under suitable conditions a gain of something like 15 per cent. has been shown.

Looking at generating stations as a whole, we have now come to a time when the chief interest really centres round the boiler-house, and its working and economies. The steam taken by large turbines per kilowatt will be referred to later; but it can now be said that they have attained an efficiency such that for every 1 per cent. improvement it may be possible to make in their economy, it is probable that 3 per cent. or 4 per cent. can be attained by close attention to boiler-room problems, now that we are getting to know the working conditions more closely. It has not been worth doing this in lighting stations so far, because the load was on for such a short time, and the price which could be obtained for the unit was higher; but now that load factors up to 25 per cent. are common, and 30 per cent. to 40 per cent. not unusual, the matter is assuming a different aspect. An example of this will make the position clear.

Losses by Banking Fires and in Other Ways.

A first-class 2,000 kilowatt steam turbine will give a unit of electric energy, or a kilowatt hour at full load for about 17 lbs. of steam, including that taken by the auxiliaries, namely, air and circulating pumps. With a boiler in full operation, and provided with economiser and superheater, this amount of steam could be delivered to the turbine, including losses in the steam pipes, for about 2 to 2¼ lbs. of coal of ordinary quality. In practice, however, with a 25 per cent. load factor a station filled with such turbines would probably not be able to place energy at the switch-board under 3 to 3½ lbs. of coal per unit, and this would be very good practice. To this the distribution losses of between 15 per cent. to 20 per cent. would need to be added before the energy reaches the consumer, so that to supply 1 unit to a customer will in all need the expenditure of, at

least, 4 to 4½ lbs. of coal, whereas, if the load were continuous, 2½ lbs. would suffice. Intermediate load factors between 25 per cent. to 100 per cent. have correspondingly reduced rates of consumption of coal; but it may be approximately said that in practice the coal needed, owing to various losses and uses in the whole plant, and in keeping turbines running at low loads for an 8,000 to 10,000 kilowatt station is not far from double what it would be if the plant were working continuously at full load. For smaller powers this discrepancy is greater. Thus the writer calculates that for a station of 2,500 kilowatt capacity—a very common size—at 25 per cent. load factor, a unit cannot be delivered to a customer, including losses in transformation, for an expenditure of less than 5 lb. coal on an average, and this would be a very good result. With a load factor of 50 per cent. the coal expenditure would be reduced to 3½ lbs. per unit sold as compared with the 5 lbs. mentioned above. The importance of securing a good load factor is therefore readily seen, as well as of operating on a considerable scale.

Possible Improvements.

It may be asked what are the probable chances of improvement in these respects. Doubtless some improvements will be made in turbine efficiency. During the comparatively short time the turbine has been in use it has been greatly improved, and I think we may assume that turbines will be improved another 10 per cent. in efficiency; but having regard to the immense amount of work which has been done on the steam engine, and the fact that turbines now nearly equal steam engines in efficiency, apart from the gain in greater vacuum, it does not seem likely that very much more than this will be done. As has already been pointed out, a certain percentage gain in engine or turbine efficiency does not mean as things stand a corresponding percentage gain on the whole coal used.

The prospects of economies in the boiler house are however more hopeful. From experience derived from burning petroleum and natural gas in boilers, it is found that 10 per cent. to 20 per cent. higher efficiency may be attained than with coal, from the fact that it is so much easier to control the amount of air admitted and to keep it closely to the actual amount needed for the combustion of the fuel. If the action of a boiler working with a modern form of chain grate stoker is observed, it will be seen that most of the combustion takes place in the fire brick chamber in which the greater part of the chain grate is situated. If the fire is watched from the side it will be found that the heating of the boiler is mostly done by a flame of hot gases almost like a blow-pipe flame issuing from the arch over the grate, so that the boiler is really heated by gases formed in a crude way in the grate. The writer is coming to the opinion that it would probably pay to carry out this process further, and to separate the furnace altogether from the boiler, burning the coal in a producer, which is much better adapted for burning coal thoroughly and economically than a grate, and then utilising the hot gases in the boiler. In this way little of the heat of combustion would be lost and the regulation of the gas and air supply would be much more perfect, for less draught would be needed, and the boiler being simplified, it could be constructed much more air-tight, and also be effectively lagged, so that the present large loss by radiation and convection would be reduced, and as the supply of air could be almost entirely cut off, the losses in keeping steam at no load and low load would be greatly reduced. A producer can also be kept banked for a much smaller loss of coal than a boiler fire grate, and is also fired up more easily and quickly. There should then be some gain of efficiency at high loads and considerable economy in losses at low loads. The presence of gas would be also most useful in enabling separately fired superheaters to be used and effectively controlled. Such a change in practice must come slowly, but it does appear that in these and other ways considerable improvements in the amount of coal needed per unit for electric energy generated may be effected as compared with present practice in stations where the load is a varying one. There is also a possible alternative, which is to use ground coal with an air blast, as is successfully done now for firing rotary kilns for cement making, but that is less promising.

It may be said, if gas producers are to be introduced at all, why not at once use gas engines? This introduces a large problem which will be referred to later; in the meantime we will pass on from the generation of steam to its utilisation.

The Generating Plant.

Within the last three or four years it has become the almost universal custom wherever generating plants of more than 700 or 800

horse-power are required to instal steam turbines. For smaller sizes steam engines are still the more economical, but for larger the superior results to be obtained from condensing with the turbine make it slightly the more economical prime mover. The turbine, however, owes the favour in which it is now held to other advantages, viz., its relative cheapness in price, the small space it takes up, and its great fly-wheel effect, and generally its adaptability for the purpose for which it is required, in which it much exceeds the reciprocating engine.

Nothing that can be said under this heading is half so convincing as a visit to a large power station in which reciprocating engines have been installed, but in which recent extensions have been made with steam turbines. Besides the above advantages, the gain in simplicity and the ease with which the whole plant can be controlled and overlooked will appeal to the most non-technical observer.

To show the gain in cost, the London County Council some years since installed several large reciprocating engines in their tramway station, which cost, if the writer recollects rightly, between £12 and £13 per kilowatt including dynamos and conductors, while they have recently ordered extensions in the form of steam turbines to the amount of 10,000 kilowatts, for which the contract price was £4 per kilowatt. The turbines are probably rather more economical in steam consumption than the engines, they take less oil, and are less costly for repairs, besides being capable of carrying a considerably greater overload. The capital cost has, therefore, been reduced to one-third in the plant itself, besides the saving in floor space, buildings and foundations, which would probably make the total cost about a fourth of that for slow-speed reciprocating engines. The gain would not be so much as against high-speed engines, but in attempting to build high-speed engines of over 1,500 kilowatts we begin to get a number of undesirable features which have prevented them ever being popular.

In supplying electric energy publicly one of the most important considerations is the maintaining of an even electrical pressure in the distributing system under all circumstances. With alternating currents the rate at which all the motors turn is governed by the speed of the generating sets in the central station; and again, if light and power are to be supplied from the same mains, and if an even turning moment is to be kept up throughout the system, constancy of pressure is very important. Now, the essence of electric power supply necessitates the throwing on of large loads on the mains in starting machinery, in hoisting, and in other operations at short notice, and it is a primary necessity that the largest loads which may be thrown on and off the mains suddenly should not affect the rate of turning of the generators and the electric pressure in the mains appreciably. In both these respects the turbine is an excellent implement for the work it has to do. Owing to the high speed, the energy stored up in the turbine rotor and the rotating portion of the dynamo is usually about three times what it would be with a reciprocating engine and alternators. The following are the approximate speeds of turbines coupled to multiphase generators of different sizes:—

STEAM TURBINES.

Size in kilowatts.	Average revolutions per minute.
500 / 1,000	3,000
1,500 / 2,500	1,500
3,000 / 5,000	1,000
6,000	750

Again, in a turbine the governor acts immediately and on the whole turbine, while in a reciprocating engine there would be at least three cylinders on only the first of which the governor would act, the steam taking quite a considerable interval to pass through all of them. Again the large overload capacity has already been alluded to. It is found that between half load and 50 per cent. overload the consumption of steam in turbines does not vary per kilowatt output more than 10 per cent. Moreover, since the motion of the turbine is purely rotary and the speed is only very slightly raised at the heavier loads, the strains on the plant are very little increased by putting on it these heavier loads which would be fatal in the working of a steam engine. Moreover, by admitting steam past the first set of blades in a turbine without serious loss in economy the output may be even doubled for short intervals, and even for large ones if the dynamo is made large enough, as it is the heating of the dynamo which really determines the amount of overload and, to some extent the condenser. While the utilisation of these forms of carrying overload is not a thing to be made use of on every occasion, nevertheless it is exceedingly important in central power supply,

first as increasing the plant reserve in case of accident, and again often enabling a short peak to be met without incurring the loss of steam, &c., in starting up a second turbine only to shut it down again after a short interval. This ability to carry overloads has hardly yet been appreciated at its full value by engineers.

The consumption of steam by modern turbines per kilowatt hour output is approximately as follows:—

STEAM CONSUMPTION OF MODERN TURBINES.

Size K.W.S.	Half load lbs. per hour.	Full load lbs. per hour.
1,000	20·50	18·0
2,000	18·25	16·0
3,000	17·00	15·0
5,000	16·00	14·5
7,500	15·25	14·0

MEASURING STEAM CONSUMPTION.

It is interesting to note that what is called the Willans straight line law applies to turbines as well as steam engines. According to this law a certain amount of steam is necessary for turning the plant round at full speed without any external load, keeping it warmed up, &c.; the auxiliary plant, such as air and circulating pumps, also needs nearly a constant amount of power. The steam taken in addition to this for doing work is found to be almost the same number of pounds per horse-power whatever the load, if the vacuum and other conditions are kept the same. Knowing the no load losses, therefore, and the consumption at some given load or the consumption at two different given loads, we can find this extra number of pounds of steam per horse-power required for the external work, and therefore can predict what the steam consumption will be at all loads. It is, therefore, easy to estimate from the station records of the output of the station, what amount of steam has been used by the turbines, and it is a point about turbines that if they are kept in order the steam consumption in actual work remains the same indefinitely. Moreover, as all the steam is condensed and returned to the boilers, by measuring this we have another check; an apparatus for measuring this returned water by means of its rate of flow through a triangular opening in a tank has lately been put on the market, and is now frequently used. The measurement is continuous, and is recorded on paper on a revolving drum. In this way a complete balance-sheet for the working of the station can be kept, including the coal and water used, the steam passing through the turbine, the air flow up the shaft, and the electrical output from the station. This offers a means of checking the efficiency of the plant very completely, and of tracing the sources of loss. Until recently no steam plants have been run under such detailed supervision as is now possible in large stations, and this ability to give that close attention besides tending to great economy should enable improvements in detail to be effected.

THE STEAM TURBINE.

It had been my intention to deal more fully with the steam turbine, but as I see that following these lectures are to come a set from Mr. Johnson Stoney, who, as collaborator with Mr. Parsons, has an unique experience of turbine building, I feel that for me to say much more would be only going over the same ground twice.

I will, however, refer briefly to the forms of turbines. About the same time Parsons in England invented one form of turbine, and De Laval on the Continent another. In De Laval's type a very beautiful principle was boldly and scientifically made use of; the high pressure steam was expanded in an expanding nozzle of peculiar shape, and its velocity and pressure greatly reduced, while the total momentum in it remained the same; in this state the steam impinges on the turbine blades, acting by its weight so to speak and not by its pressure; good results were obtained, but the velocities required were so high that the mechanical construction became awkward, and though used to a certain extent this form of turbine never became popular. When, however, Parsons had developed his type of turbine with a number of rows of blades, the construction of larger sizes of the De Laval type was taken up by experimenters on the Continent, notably by Zoelly and Rateau, and in America by Curtis. By adopting De Laval's principle but breaking up the action into a certain number of stages, they reduced the velocity nearly to that required by Parsons, and produced a practical machine. Engineers in this country, however, were for a long time suspicious "that the power could not be taken out of the steam" in so few stages, and, at any rate, the Parsons type has enjoyed the greater vogue. Continued sucecsses, however, have been achieved with the Impulse type, and the two classes of machine are now openly competing on similar guarantees of steam

consumption. The advantages of the Impulse type are a more mechanical and robust consideration, a reduction in length, the practical abolition of the dummy balancing piston, and, lastly, the fact that considerable clearance can be left between the revolving and stationary parts without loss of efficiency.

This type is now being accepted by engineers for the largest contracts, and a great number have been installed in America and on the Continent.

If it proves as lasting as the Parsons type, and as free from cutting of the blades by high-pressure steam, a step forward in turbine construction will have been made of considerable importance. Probably the ultimate turbine will be a combination of the two principles.

From the turbine we will pass to its condenser. During the last three or four years, and since turbines came prominently forward, a great deal of work of a detailed character has been done on this class of plant, including the introduction of the Edwards Air Pump, improved types of circulating pump, better arrangement of the flow of the water through the condenser, the Parsons vacuum augmenter, and other details, which now make it possible to maintain a vacuum of 28½ inches under heavy loads.

The high speed of the turbine is in many respects in favour of the dynamo which is attached to it, and greatly reduces the amount of material necessary in construction as compared with low-speed machines, though a number of new mechanical problems are introduced owing to the centrifugal forces brought into play, and these need very special treatment. I will not go into detail further, as I understand that Mr. Johnston Stoney will treat these points in his lectures, except to notice a considerable improvement in the excitation of alternating generators by means of a magnetic shunt on the exciter, which, with alternating currents, automatically permits a much closer regulation than was previously possible, reducing the fall of pressure on inductive circuits of ordinary character between no load and full load from about 18 per cent. to about 6 per cent.

Multiphase alternators are made to run on turbines to give as high voltages as 11,000 to 12,000 and succeed well. It is, however, becoming doubtful whether in large installations, considering the cheap prices at which transformers can be obtained and their high efficiency, it is not better to operate the dynamos at lower voltage and transform up to the requisite pressure. This is especially the case if current at different pressures is sent out from the power house for feeding the near and more distant parts of the district.

Controlling Plant.

Under this heading comes what is generally known as the "switch-board." During the last few years the design and arrangement of this part of the station has been so developed and altered that switch-board is almost a misnomer.

In large stations now the operation of the switching appliances are often controlled from a central control board, which not only operates these but also the stop-valves of the turbines, which are in themselves operated by motors. The engineer in charge of the switching gallery can in this way start any turbine, put it into parallel with other plant running, and can connect or disconnect any feeders at will.

The central portion of the switching plant is the bus-bars, which are usually situated above the rest of the plant, and sometimes there are subsidiary bars, so that some portion of the station can be worked independently from the rest. Conductors from the alternators are connected with their switches and the necessary measuring instruments to these bars, and again from them the feeder circuits branch, passing on their way again through the requisite switches and measuring instruments.

Before the conductors from the alternators reach the bus-bars it is now becoming the practice in large stations to take off a connection for working the auxiliaries of each turbine so as to maintain each as an independent working unit.

The bus-bars themselves are usually bare copper conductors carried on insulators, in a separate fireproof longitudinal chamber, extending the whole length of the switch gear.

The working of all the controlling apparatus is based on the use of the oil immersed switch. The merit of oil for the purpose of breaking an arc was, I believe, first pointed out by Professor Hughes, and it may almost be said that station control at the pressure and for the powers which are now quite common is impracticable without this very simple expedient. These oil switches are operated by levers for moderate sizes, but the larger ones are usually actuated by special electro-magnets or small motors. In this case the switches are usually located away from the switch gallery, often in a gallery by them-

selves, each in its separate compartment, and all controlled by local electric circuits brought to some central point.

On account of the noise made by the turbines it is now frequently arranged that the switch operators for controlling the feeders shall be situated in a separate building. The attendant then can be placed in telephonic communication with the different sub-stations on the circuit, and can watch the indicating instruments on each feeder and manipulate them as desired.

To deal with the details of various switch boards and measuring instruments would need a set of lectures alone, such is the amount of thought and care which has been lavished on them, but the general construction and method of operation will be understood from the lantern slides shown.

The Distributing System.

Outside town areas power supply work has so far been carried out chiefly at pressures of from 6,000 to 12,000 volts; in the case of the power companies principally at the latter pressure, while the Newcastle company has now considerable lengths of cable working at 20,000 volts pressure. These pressures relate to the voltages between the phases of a three-phase supply, the system on which practically all modern public supply work on any scale has been carried out; this is proving itself the most economical and flexible of the different possible systems; in fact, several of the large towns having low pressure continuous current lighting plants have had to instal separate three-phase high pressure plant for supplying power.

For supply at these pressures cables insulated with paper saturated with rosin oil or some special kind of mineral oil are universally used, the paper being protected by a lead covering. It does not appear that anything is likely to arise to displace cables made in this way, since paper is cheap and the experience of its use which has been obtained during the last 16 or 18 years has been most satisfactory, both as to its durability and its power of withstanding continuously such pressures as have been mentioned.

The only drawbacks to the use of paper cables are that paper depends almost entirely for its insulating properties on the lead sheath remaining permanently intact and the joints being made carefully under proper conditions. A very slight amount of moisture which may make its way through a small puncture in the lead covering, or may get in through an unguarded and exposed end of cable, will usually be fatal to the insulation in a short time. The skill used in modern manufacture has, however, brought it about that there is very little risk of imperfection in the lead covering except from actual violence, and with careful jointing and laying, long lengths of these cables can be depended upon to work without fault from year's end to year's end, and any faults which do occur are nearly always located at the joints.

Such failures as do take place are usually due in the first place to resonance effects. This is a sudden rise of the electric pressure in a circuit, due to the release of stored up energy when a circuit having self-induction or capacity, as most alternating circuits have, is suddenly broken, as by opening a switch or breaking the circuit in some other way.

Methods of Laying Cables.

Cables are most cheaply laid by armouring them, covering with preservative compound, and laying them direct in the ground. In places where they may be disturbed it is usual to give them further protection by laying them solid in troughs filled with bitumen or pitch, or they are laid in earthenware, iron, or specially prepared conduits of fibre or cement. Much of the cable for power supply has been laid in conduits, mostly of earthenware, as two or more ducts can be laid at the same time, and this permits a second cable in case of extension to be easily and quickly added, or an existing cable to be drawn out for repairs or for replacement by a larger size.

Costs of Cables.

Approximate costs of such cables, including laying, were given in the first lecture, and are here repeated for reference:—

Section of cable. Square inch.	Approximate capacity in kilowatts up to	Cost per mile. £.	Cost per kilowatt capacity per mile. s. d.
·05	750	900	22 0
·10	1,500	1,200	16 0
·20	3,000	1,700	10 6

Probable Improvements in Cables.

The improvements likely to be achieved in this part of the work are the perfection of the insulating qualities of the paper covering of the conductors, by which either higher pressures may be safely employed with the same section of insulating material, or a reduction of thickness in the insulation would be permissible

for the same pressure, thus enabling a reduction to be made in the diameter of the expensive lead covering. Having regard to improvements in the manufacture, there is no doubt that the sections of paper at present in use are above what are really needed, these being governed rather by the thickness necessary to withstand occasional resonance effects than by the thickness necessary to withstand permanently the ordinary working pressure.

Resonance effects have already been alluded to. There is no subject which is in need of further investigation than this at present. The theory is clear, but the effects are difficult to follow in complicated circuits. The lecturer is, however, strongly of opinion that further careful study will result in these effects being reduced without undue expense until they are almost negligible, and this will enable considerable economies to be effected in the cost of cables, as it will permit the margin of safety now necessary to be considerably reduced.

Resonance effects in cables are guarded against by spark gaps and by the use of high non-inductive resistances, such as water, when switching on and off circuits, and in motors and transformers by the use of inductive resistances in series with them at starting; the use of condensers for the same purpose is also increasing. It is, however, to be noted that, as circuits get larger and have more plant connected to them, the effects of resonance gradually become less.

Overhead Mains.

In the more open districts the use of overhead mains is now making some way in this country. While this class of work has been almost universal on the Continent and America, it is only within the last few years that legal and other obstacles have permitted it to be adopted to any extent in the United Kingdom. Now, however, several of the power companies are doing a good deal of overhead work, the costs approximately being about half that for cables; while the overhead wires have the advantage that faults are very easily found and repaired, so that there is less necessity for duplicate lines than with cables. Such circuits are in use up to 30,000 volts in this country. The work is being done in a very superior style and very substantially. I have a number of slides illustrating work of this character, chiefly in the county of Durham, which will explain its characteristics better than can be done except by a highly technical description. The usual spans are 40 to 50 yards, and when crossing roads or railways the live mains are provided with cradles beneath them, to prevent any accidents should a wire break, though the chances of this are almost infinitesimal. Very little trouble from lightning is being experienced, and the modern form of lightning arresters is adequate to deal with any effects which take place.

THE LOTTERY IN ITALY.

The Times recently published some curious statistics on Italian lotteries, furnished by its Rome correspondent:—

The accounts of the State lottery for 1907-1908 show an increase of receipts to the amount of £120,000, or a total of £3,336,000 of gross receipts in the year. Of these gross receipts £1,600,000 went back to the players in the form of prizes, and a profit of £1,736,000 remains to the State after the deduction for expenditure. This is the highest figure that the "Lotto" has yet reached in a year, and more than one newspaper seems to experience searchings of conscience over an increase of revenue from such a quarter.

Certainly a comparison of the local statistics of the Lotto with other figures yields a curious result. One need hardly say, to begin with, that the great majority of the Lotto players are in the south of Italy. The curve of average Lotto play seems to follow roughly the curve of illiteracy. For instance, to take the average of play in proportion to the population of some towns. In Sordrio, the average spent by each inhabitant on the Lotto would be 21 centesimi, the average of illiterates 16 per cent.; Como, 1 lira per inhabitant, 17 illiterates; Turin, 3½ lire, 13 illiterates; Rome, 4½ lire, 43 illiterates; Naples, 14 lire, 54 illiterates. The evidences of thrift are, naturally, in the contrary proportion. In Sicily, where average Lotto play is 10 lire per inhabitant of the big towns, the average deposit in savings banks is 41 lire; this average deposit rises to 120 in Piedmont and 174 in Lombardy. It would seem, too, that the great supporters of the Lotto are the poorest of the poor. More than half of the tickets sold are for sums below fivepence. Tickets of over half-a-crown hardly account for one-tenth of the receipts. The *Stampa* of Turin laments the fact that the State should derive such profit from the most poor and ignorant of the populace. It can at least be urged in extenuation that the case is hardly serious, since the same populace which gambles away £3,336,000 in the year, puts £56,000,000 into the savings bank during the same period. It would be more to the point, says the correspondent, to complain that the State should play with such unfair chances in its favour. A lottery arranged on a scale that leaves it an almost certain winner of half the

money played does not seem particularly just; and that, during the last five years, has been the position of the lotto in Italy. One thing is certain—namely, that the poorer and more ignorant population will gamble in some way or other, and that if the State will not give them an opportunity of tempting fortune they will find opportunities for themselves elsewhere.

In reply to the *Times* writer's comments it may fairly be urged that the lottery in Italy is a source of State revenue, and that so long as the gamblers do not mind taxing themselves to the extent of 50 per cent., there is no reason why the State should not limit the prizes to any amount which serves to attract the gamblers.

THE CUTCH INDUSTRY OF BORNEO.

Cutch is a hard, brown, brittle substance, and when broken presents a smooth shining surface like anthracite coal. It is used for tanning leather and also for dyeing textiles, black or brown. Sandakan has a prosperous cutch factory, which produced and exported 830 tons in 1907 and 970 tons in 1908. Cutch is manufactured in Dutch Borneo and at Mempaked across the bay from Kudat. The cutch is made by these factories from the bark of the mangrove trees which grow in great abundance in salt marshes, extending inland in various places in North Borneo as far back as one hundred and twenty-five miles. The American Consul at Sandakan says that large fleets of small native boats collect and transport the bark to factories. The trees after being stripped of the bark, are, as a rule, cut down, split, and chopped for firewood, loaded into small boats, and finally exported to Hong Kong and other ports. The wood makes an excellent fuel for steam launches. The mangrove bark after delivery to the factory is subjected to the treatment found to be most effective in extracting the tannin and reducing it to solid commercial form. Cutch is by no means a new substance, having been used by the ancients for dyeing a permanent black or brown. It is obtained from many species of the acacia. In India they cut the whole tree into chips, which are boiled until the tannin is extracted; then the exhausted chips are taken out, fresh chips put into the kettle, sometimes with leaves and twigs, and the process repeated until the liquor acquires the consistency of coal tar. It is then poured into moulds, where it hardens, after which it is made into balls and wrapped in the leaves ready for market. Cutch of an inferior quality is made from the Areca palm, also from a plant called gambier, which grows in Borneo. It is made and sold by the natives. The value of the gambier exported from Borneo in 1907 was £1,140. Cutch is also largely produced in Sarawak and Dutch Borneo, and goes to increase the exports of these countries. The vast extent of the mangrove swamps in North Borneo, their easy access and the excellent quality of the cutch produced, promises an increasing trade in this useful and necessary product. As the supply of oak and hemlock bark is constantly growing less in the United States, the demand for cutch will increase. The mangrove trees are said to exist in some of the Phillipine Islands in abundance, but they have not as yet been utilised.

THE PRODUCTION OF KAPOK IN JAVA.

Kapok is an article produced extensively in Java, and many hundreds of bales are exported for upholstery purposes, filling beds, pillows, coverlets, &c. The kapok tree, which grows to a height of 25 to 30 feet, is cultivated at sea level, or at as great an elevation as 2,500 feet, but the best material is secured from trees grown at an altitude of not more than 600 feet above the sea. On the high lands the tree bears less fruit, and yields later in the year; often before the fruit is ripe, the rainy season is on, and the water penetrating the fruit before it is properly ripe, damages the fibre, so that the kapok is inferior to that cultivated at a lower altitude. Rich sandy clay is considered the best soil for cultivation of kapok, and it appears to thrive better when planted near the sea on a fair elevation. The ordinary method of propagating the tree is by setting out cuttings from older trees. It is also propagated from seeds. The trees propagated from cuttings do not have so vigorous a growth as those propagated from seed, neither are they so long lived. The trees grown from cuttings bear fruit in three years, being then in full bearing and ready for harvesting, while those propagated from seed begin to bear fruit after two years. Of course much depends upon the soil and climate. Seed for propagation is sown during December or January—the middle of the rainy season—and covered with a thin layer of soil. The seeds are sown in rows about twelve inches apart. When the young plants are about six or eight inches high, the soil is well cleared from them, in order that they may be well exposed to the sun, as kapok plants require much sun, and must not be kept in the shade. At this stage the plants must be thinned out so that they are at least twelve inches apart. All that is required until the plants are eight months old is to keep them well watered and weeded. Then they can be set out, and should be planted about 135 to the acre if the ground is intended solely for kapok growing. Up to the present time very few kapok plantations exist, and the trees are generally cultivated together with other crops. This does not harm the kapok tree as long as the roots of the tree are free from those of other growths. In planting, the young trees are stripped of all their leaves and cut off to a length of about two feet. This is necessary to prevent the plant from withering at the top. It is often the custom to plant pepper and serih vines near kapok trees and to allow the vines to grow upon them. This, however, has been found to be a great mistake, for nothing should be planted near the trees, which require all the nourishment the soil can give. After

the kapok tree is some four years old, however, such vines may be allowed to grow upon them without harm. The kapok tree begins to yield in two to three years and at its fifth year is bearing its best. At this period an acre of 135 trees should produce about 420 pounds of clean kapok annually. Some well matured trees have yielded as much as 125 pounds of clean fibre a year, but this is rare. The tree blossoms in April or May and the fruit ripens generally the latter part of October or in November, when it takes on a yellowish brown colour, and breaks open. Then the fruit is gathered and before the rains set in, otherwise the water would damage the fibre. In some cases the fruit is gathered before it breaks open, and it is opened and the fibre taken out as soon as possible, otherwise if left too long in the fruit the fibre becomes yellow and loses its glossiness. The seeds are separated from the fibre by beating with sticks so that the seeds fall out. This sometimes causes the seeds to explode and the entire lot of kapok is destroyed by fire. To clean the kapok properly it is laid on a large bamboo grating and the beating process goes on until all the seeds fall through the grating, and the clean fibre remains. A more modern way of cleaning the kapok after it has been taken from the fruit, is by a hand machine, consisting of a horizontal cylinder, the inside of which is lined with rows of pegs placed vertically on the sides of the cylinder. An axle, also fitted with pegs, turns on the inside, and threshes the kapok inside the cylinder, which is put in through a funnel. The cleaned fibre drops out through an aperture, and the seeds drop through a perforated iron at the bottom of the cylinder. This is also a very slow cleaning method, and good modern machinery is much needed in Java. It is stated that 450 of the fruit will give about one pound and a quarter of fibre, and two pounds and a half of the seed. When preparing for shipment, it is packed in bales, covered with bagging or mats and pressed, either by hand or hydraulic power, into bales weighing about eighty pounds. Great care is necessary to prevent the bales from being pressed too tightly, for should this be done the fibre would lose much of its elasticity and value. Oil is manufactured from the seeds, and exported mostly to the Straits Settlements. The residue makes a good fertiliser, containing about five per cent. of nitrogen.

SCIENCE COLLECTIONS AT SOUTH KENSINGTON.

A deputation, representing the principal Scientific and Engineering Societies of London, waited on Mr. Walter Runciman, M.P., President of the Board of Education, on Tuesday, the 13th instant, to present a memorial on the housing of the Science Collections at South Kensington.

Sir William Anson, in introducing the deputation, said that the memorial was most important, not only in itself, but because of the names by which it was supported. No doubt Mr. Runciman was aware of the crowded and unsatisfactory condition of the South Kensington science collections. What they asked was that the collections should have room for rearrangement and expansion. They believed that a site was available, and that if it were taken the Government would not have to provide funds for the purpose. They asked that the museum, which represented the application of science to material, should be placed in the same position as art and natural history by the Government of the country.

Sir Henry Roscoe and other members of the deputation having spoken ;—

Mr. Runciman, in his reply, expressed his appreciation of the great value of the collections, and the need for a suitable building in which they could be properly arranged. He approved of the suggestion that part of the funds of the Commissioners for the 1851 Exhibition might be used for the purpose, and promised to bring the matter before his colleagues in the Cabinet, and to use his personal influence in furthering the objects of the deputation.

HOME INDUSTRIES.

Acts of Parliament and the Working Classes.—From time to time, and irrespective of the political colour of the party in office, the House of Commons puts upon the Statute Book Acts designed to ameliorate the condition of the working classes. Unfortunately, the effect of this legislation is often very different to what was anticipated and desired, and, instead of benefiting the classes it is intended to serve, it injures them, and more particularly injures those least able to look after themselves. We are seeing at the present time a great derangement of one of the most important industries in the country, that of coal, consequent upon the coming into force of an Act of Parliament—the Eight Hours (Miners') Act. The object aimed at here was one with which all generous-minded men must sympathise. It was to shorten the hours of labour of men engaged in peculiarly exacting work underground. But the immediate result has been to bring about disputes between master and man that are by no means settled. In South Wales, indeed, some sort of agreement has been arrived at, but the coal masters and coal workers of Scotland are in hot dispute, and there is some likelihood of a lock-out which may involve the whole coal industry of the United Kingdom. In Staffordshire, again, we have only recently seen thousands of pit lads on strike because, as they allege, and with some show of reason, the Act, whatever it may do for others, is distinctly harmful to themselves. It may be hoped that these disturbances in the coal trade will not end in the acute conflict so many fear, but it may well be questioned whether the Act will not do more harm than good to those it was intended to serve. And so with other

Acts passed in earlier years. They, too, were intended to improve the condition of the working man, but in not a few cases they have had the contrary result, and the sufferers have been the weakest members of the section of workers affected. For example, the Employers' Liability Acts have meant throwing tens of thousands of men out of work, because, apart from those workers to whom employers used to give work, but whom they are now afraid to employ on account of their physical condition, and consequent likelihood of making claims for sickness or disablement, there is a tendency to increase labour-saving machinery to combat the heavy disbursement of insurance premiums. To take an illustration from the shipping trade. Many a sailor is now unable to find employment because he is medically unfit to pass an examination which owners must insist upon to safeguard themselves against unscrupulous claims being made. Again, the compensation to domestic servants has been a serious misfortune to the older and weaker class of workers, who can no longer get employment. Employers who were content in the old days to put up with some physical weakness, are no longer prepared to do so, having regard to the heavier liabilities resting upon them. It is not, of course, suggested that Parliament should cease to pass measures for the amelioration of the condition of the workers—far from it—but it is well to point out how necessary it is that there should be exhaustive discussion of proposed legislation, and discussion by men with practical knowledge of the particular trades affected, before existing laws are repealed or modified.

Electric Lighting Amendment Bill.—Considerable dissatisfaction is being expressed by some of those who desire to see the electric industry of the country advance more rapidly than it has hitherto done in connection with the Electric Lighting Acts (Amendment Bill) now before the House of Commons. It is contended that this Bill does not touch the weakness of the Electric Lighting Acts of 1882 and 1888, or, if it does so, it rather increases the objectionable features of those Acts than removes them. Some eleven years ago a Joint Committee of both Houses, of which Lord Cross was Chairman, recommended among other things the abolition of the municipal veto on electric supply schemes. Four years later the Institution of Electrical Engineers sent a deputation to the Board of Trade urging changes on the lines laid down by the Joint Committee, and the then President of the Board of Trade stated that a Bill had been drafted to give effect to the suggestions of the Committee. In 1903 the Bill was printed, and in 1904 it was considered by a House of Lords Committee, amended, and passed through the Upper House. Nothing more was done with this Bill, owing probably to the change of Government which took place in 1906, and it was not until the present session that the Government again took up the matter. The result is the Electric Lighting Acts (Amendment Bill) now before the House of Commons. It is a measure very different from the Bill drafted by the late Government on the lines of the Cross Committee. There is, for example, no provision for the modification of the veto, or the relaxation of any one of the worst restrictions upon private enterprise and electricity supply. The Bill has already passed through the House of Lords, and the Government are making a determined effort to get it through the House of Commons, but it is feared that if it becomes law the spirit of the Electric Lighting Acts of 1882 and 1888 will become dominant for an indefinite period. Moreover, if the Bill passes it is argued that one of its principal effects is likely to be the strengthening of local authorities in their competitive and other relations with electric supply companies. It is held by the opponents of the Bill that it will, both by what it enacts and what it fails to enact, do nothing towards encouraging the investment of capital in the electrical supply industry, but rather the contrary. Of course, this is only one side of the question, but it is much to be hoped that Parliament will do nothing to discourage still further private enterprise in electrical matters.

Coal Exports.—The volume of our foreign coal trade during the six months ended June last was greater than for the first six months of 1908, the actual quantities sent abroad being 30,421,691 tons, as compared with 30,024,552 tons in the corresponding period of last year, an increase of 397,139 tons, equal to 10 per cent. Prices have fallen heavily both in the home and in foreign markets, and in South Wales the fall in the export prices of steam coals has been greater than in any other class of fuel owing to the effect on average f.o.b. quotations on the prices of coal shipped under contracts. In the average f.o.b. price Cardiff large steam coals, there has been a drop approximately of 2s. 7d. per ton. The activity in May and June was due largely to the prospect of labour troubles leading to a stoppage. Foreign powers were also alarmed, and pressure was brought to bear on the collieries by coaling companies and foreign companies, and the Admiralty, to expedite delivery of contract coal. The temporary increase of current demand over current supplies drove up market quotations from 5s. to 6s. per ton higher than those prevailing up to the end of April; but the settlement of the labour crisis was followed immediately by a relapse to the old level, and it is quite possible that prices will go lower before the end of the year. It may be expected that business will be considerably less active in the second half of the year, and the effect of the Eight Hours' Act upon output price and export has still to be made known. On the one hand it is believed that the reduction from 54 to 48 hours in the number of hours to be worked per week in the South Wales coalfield will have a serious effect, whilst on the other hand it is expected by some that the reduced hours will be counterbalanced by fewer absentees, an increased efficiency of labour, and improved methods of working. It is

only by experience of the actual operation of the Act that it will be known which view is the correct one.

Fishguard and the Cunard Company.—It is believed that the Cunard Steamship Company have it in contemplation to make the Pembrokeshire port of Fishguard a port of call. Now that the London and North-Western Railway Company is in closer contact with the White Star Company, owing to that line having made Holyhead a port of call for their inbound Liverpool steamers, the Cunard Company naturally wishes to strengthen its position by a similar alliance with the Great Western Railway Company. The distance between New York and Fishguard is 2,902 miles. It is nearer to New York than is Holyhead by 40 miles, than Liverpool by 110 miles, than Southampton by 175 miles, and than Plymouth by 55 miles. Trains can easily be run between Fishguard and London in 4¼ hours, as against 5¼ hours between Holyhead and London, and 4 hours between Liverpool (riverside) and London. It is only fifteen months since the potentialities of Fishguard as an ocean passenger port were first tested. Since then, all the Booth line passenger steamers have called there. Alongside the breakwater, there is space for quay accommodation for vessels 790 feet in length, the length of the *Lusitania* being 780 feet. The inner harbour is almost entirely protected by the quays and breakwaters, and contains an anchorage area of 85 acres, which is being dredged to a uniform depth of 40 feet, the bed being soft and rockless.

Workmen's Compensation and Insurance Companies.—The tariff insurance companies are about to raise their premium rates for workmen's compensation business in the cotton trade. The proposed new rates are 20s. for £100 of wages paid for mule spinning, 10s. 6d. for ring spinning, and 4s. 6d. for weaving. A large number of firms in the cotton trade are insured through the Federation of Master Cotton Spinners' Associations, the Blackburn Cotton Accidents' Company, and the Cotton Trade Accidents' Association, of Manchester, the latter being practically a mutual association of about 100 firms, the premium rates being 10s. 3d. for mules, and 3s. 3d. for rings and looms. A number of insurance companies are about to forward a memorandum to the Government directing attention to the limitations of the Assurance Companies' Bill. It will be urged that the requirements as to deposits which apply to all companies transacting life assurance should be applied to all existing fire and accident companies, as well as to companies which may be established in the future for the purpose of transacting these classes of business. The memorandum will also direct attention to the fact that the Bill contains no definition of an underwriter, and suggest that a minimum equal to 33⅓ per cent. of the premium income should be stated in the Bill as the reserve to be set aside by all companies for unexpired liability in respect of fire, accident, and employers' liability risks.

GENERAL NOTES.

ELECTROLYSERS IN LAUNDRIES.—In German hospitals the electrolytic treatment of soiled linen is already very general, but hitherto in this country the treatment has not been adopted. Now, however, the Manchester Infirmary has begun to use that invented by Haas and Oettel. The construction of the apparatus is simple. It consists of the electrolyser proper made of stoneware, a brine dissolver of wood provided with an agitator, foot valve and let-off tap; a stoneware collecting tank, and the necessary switchboard. In operation the brine dissolver is filled with a measured quantity of water, to which is added a given weight of common salt, which is dissolved by a few turns of the agitator. As the brine is allowed to run through the electrolyser the electric current is turned on, the result being an electrolytic liquor of constant strength. The liquor runs into the collecting tank below, from which it is withdrawn for immediate use. The amount of electric current employed is very small. Chlorine is one of the most powerful disinfectants known, and is also the most perfect bleaching agent. By means of these electrolysers neutral sodium hypochloride can be produced in all strengths from 3 to 14 grammes per litre. It is said that one of the advantages of the system is that clothing may be treated with it week after week without being injured.

INSURANCE OF EMPLOYÉS IN GERMANY.—In his report on the trade and commerce of Westphalia and the Rhenish Provinces, just issued (No. 4283, Annual Series), Mr. Consul-General Koenig refers to the new law for the insurance of *employés*, and says that it lies very heavily on the shoulders of employers, as the latter have to pay half the legal contributions towards insurance. Besides these burdens there are to be new regulations issued as to compulsory contributions against illness, increased waterway and canal dues, reduced hours of labour in certain trades, a general widow and orphan insurance, and increased telephone charges. It is, the Consul-General considers, very questionable how much more trade and commerce can be conveniently burdened without hampering their very existence. Statistics show that the wealth of Germany has increased, but the very large increases of late years resulted from exceptionally good times and large turnovers, and not from interest on capital invested. It is a remarkable feature of the times in Germany that it is becoming an absolute necessity for German Ministers to meet in conference representatives of the banking interest, and of the many syndicates, in order to talk over commercial, industrial, and economic matters. The result of such meetings of the Government with representative deputations promises to be of far-reaching importance in influencing the legislation of Germany in the interests of the trade and commerce of the Empire.

Journal of the Royal Society of Arts.

No. 2,958. VOL. LVII.

NOTICES.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

This competition was instituted in 1878 by the Council of the Society of Arts, as trustees of the sum of £400, presented to them by the Committee of the Owen Jones Memorial Fund, being the balance of subscriptions to that fund, upon condition of their spending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes are awarded annually on the results of the national competition of the Board of Education, South Kensington.

Six prizes were offered for competition in the present year, each prize to consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and a Bronze Medal.

The following is a list of the successful candidates:—

Cheetham, Humphrey, School of Art, Macclesfield. Designs for Printed Velvet Hangings.

Cope, Fred., School of Art, Macclesfield. Design for a Tea-Table Cloth.

Heaton, Samuel, School of Art, Shipley. Modelled Design for a Wall-filling.

Hirst, Joseph, School of Art, Macclesfield. Design for a Tapestry Hanging.

Malins, Louis M., School of Art, Macclesfield. Design for Furniture Silk.

Mason, Arthur, School of Art, Macclesfield. Design for Figured Silk Dress Material.

The next award will be made in 1910, when six prizes will be offered for competition.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE PUBLIC SUPPLY OF ELECTRIC POWER.

By G. L. Addenbrooke, M.I.E.E.

PART IV.*

Extension of Supply Mains over a District.

In laying out a distributing system, the point to aim at is to arrange this as far as possible in loops, so that every customer may be approached in two ways, while there is as little duplication of cables over the same route as possible. Cables should be looped where practicable into customers' factories in preference to making T joints, as in case of faults loops are much more easily dealt with; and if the loop is complete, when a fault occurs, only the damaged section need be cut out, and all the customers can be kept supplied from one or other end of the loop while repairs are carried out on the faulty section.

The remaining important factors in the distributing system are the transformers. During the last few years the discoveries of new alloys of iron, in which the losses are little more than half those previously usual, have enabled great improvements to be effected in transformers and higher efficiencies to be attained. The no-load losses in the class of transformers used generally in power supply do not exceed 1 per cent., and the efficiency of the transformers under load will average about 97½ per cent.; when transformers are used in works at sub-stations, they can also often be cut off when not required, and in this way the transformer losses in such systems can be kept down to a very moderate figure.

* The Course consisted of three lectures, delivered on January 18 and 25, and February 1. In re-arranging the material for publication, the lecturer has preferred to divide it into four parts.

The cost of transformers themselves is also very moderate. The smaller types cost about £2 per kilowatt, 50 kilowatt transformers about £1 10s., and 100 kilowatt sizes about £1 per kilowatt, while larger sizes such as 400 to 500 kilowatts will not average more than 10s. per kilowatt. It not infrequently pays under these circumstances to use double transformation when a number of small customers have to be served, reducing the pressure first at a sub-station from 20,000 or 10,000 to say 3,000 volts, and distributing to the individual customers at this pressure. In this way a considerable simplification and reduction of costs of the customers' switch gear can be attained, and complication of the main high-pressure circuits is avoided. The laying out and arranging of local distributing systems is one of the points in power supply which calls for the best exercise of judgment and discretion.

Waste Heat Stations.

The supply of energy into the same distributing system by subsidiary power stations located at different convenient points has already been mentioned as having been employed by the Newcastle and its allied companies on a considerable scale. This is a development which will undoubtedly be utilised more extensively in the future, as it is found that stations situated widely apart can be effectually arranged to work in parallel supplying into a single network.

Such stations are advantageous in at least two ways. In the first place, if there is any point where waste heat in the form of gas, whether from coke ovens or blast furnaces, is available, or exhaust steam for use in low-pressure turbines, or dust from dust destructors, the cheap supply of energy can be taken advantage of. Again, each local station, if situated on a looped main, enables a greater amount of power to be supplied with the same network than if the supply was from a sub-station, thus becoming an important factor in reducing the cost of the distributing system per kilowatt. When possible, such local stations are best kept in operation continuously, variations in the supply being taken up by the main controlling station, which also, in case of breakdown of the local plant, can maintain the service uninterruptedly. But they may occasionally be used with advantage for peak loads. As an instance, the Charing Cross Company are using the Diesel oil engine, situated at various points in their supply mains in the City, for the purpose of meeting sudden loads due to fog and the heavy peak loads they get at other times. Their value in this case is in preventing falls of pressure in the local distribution system, and in saving the capital cost of mains in a place where they are so expensive and difficult to lay as in the City. For this reason it is not necessary, as a rule, to install spare plant in the local stations which are thus cheaply constructed. As networks grow it will pay occasionally to install such stations even when the power has to be generated in the ordinary manner. By the help of the telephone subsidiary stations can be worked almost as easily as if they formed part of the main station.

Location of Faults.

One of the most important things in connection with a distribution system is to arrange that, on any fault occurring, its effects shall be localised and its position shall be indicated in the shortest possible time. A number of different schemes for effecting these objects have been devised, of which the chief involve the use of time-element cut-outs, or of balanced transformers, the most complete system in the latter case being known in this country as the Merz-Price.

In the time-element system, at each sub-station there is an oil switch on each side of the loop. This oil switch, when closed, compresses a spring, and the handle is kept in place by a catch. This catch can be released by the action of an electro-magnet, round which flows the main current or a current taken from a series transformer in the main.

The electro-magnet has an armature, to which is attached a clockwork mechanism, or a simple graduated fuse may be used instead. If the current in the circuit exceeds some given amount, the clockwork is set in motion or the fuse ruptures. In either case the action takes place in some predetermined time, after which the catch is released by the movement of the armature and the switch is opened automatically.

This arrangement cannot be worked with a closed loop, but if two lines forming a loop are cut at some point, the time of action of the circuit can be graduated, keeping the longest action near the power station. Then, if a fault happens, the line should be broken at the farthest sub-station from the generating station which is on the near side of the fault. If, then, a no-voltage release is placed at the end of the main it can be arranged to throw over the undamaged portion on to the second

main, though the remaining portion of the circuit on the faulty main will then have its time-element cut-outs in the wrong order, and this may necessitate resetting them before the main can be used. This arrangement, while of considerable use, especially on single cables, is therefore by no means perfect, particularly in complicated systems; the action of the cut-outs is also liable at times to irregularity due to resonance effects or sudden short circuits.

Balanced Transformer System of Mains Protection.

The balanced transformer system of protection is much more perfect though more expensive, since it needs a small three-core pilot cable alongside the main cable between each two sub-stations; it will, however, I think, be adopted on complicated networks in future, as it has the great merit, if working properly, of cutting out the faulty section only, so that, if each customer is on a loop, a fault merely cuts out the faulty section on one side of him and all the customers' services are kept going. Further, it is applicable to working with a closed loop, and it should also locate the faulty section at once, obviating the delay of testing long lengths of cable for a fault and enabling the repairing gang to proceed without delay to the faulty section and start repairs. Lastly, each section being complete in itself and independent of other sections, it can be applied to large systems without increased complication.

Briefly, the action of this arrangement is as follows:—On the three main circuits entering and also leaving any sub-station three series transformers are placed, the secondaries of which are connected to three pilot wires which are carried in the cable trench to the next sub-station, where they are joined up to the secondaries of another set of three series transformers, but arranged so that the pressure is in opposition to the first set. As long as the main cable is perfect the same current will evidently flow through both sets of series transformers, and consequently no current will flow through the pilot wires. If, however, a fault of any kind, whether by going to earth or short circuit, occurs on the main cable, the current flowing through one or more pairs of the series transformers will differ, either being in the same direction or one being greater than the other, if the direction of the current is maintained; a current will then flow along one or more of the pilot wires. Any current flowing through these pilot wires works a relay at each end, and thus operates the oil switches, which are maintained closed by a spring and cam, as when using time-element cut-outs. The oil switches at either end of the section then open, and the faulty section is cut out.

Except for the expense of the pilot wires and transformers it is difficult to conceive a more perfect arrangement than this, although it wants some care in operation to obviate the effects of resonance, should such be set up; its use, however, constitutes a most important advance in the protection and operation of heavy and complicated main circuits. For the protection of customers' circuits and circuits of less importance, another form of automatic cut-out which is cheaper and more compact is coming into use. This consists of two or three electro-magnets erected on the poles of the oil switch, and surrounded by solenoids through which the main currents passing through the switch flow. The cores of these electro-magnets attract an armature, and if the current exceeds a given amount, the armature moves and releases a cam by which the switch is released, and the current interrupted.

A time-element can be added to prevent too sudden a movement of the armature. On account of its compactness and cheapness, as compared with the use of series transformers it is probable that this arrangement will have extended uses in the future.

Switches and Sub-station Gear.

The oil switches and switch gear which are used on the feeders, and at customers' sub-stations, take many forms, each manufacturing company, as a rule having its own type. Most of these types are well known.

Speaking generally, a customer may be connected to the network by a single branch line, by a looped-in cable on a single line, or by a looped-in cable on a loop, and their connections may be made directly off the main feeders or may proceed from the sub-station having a subsidiary network.

A single branch line is usually called a T-junction. In this case the arrangements are very simple, consisting of an oil switch with automatic electro-magnetic cut-outs attached to the switch and operated by means of series transformers inserted on the incoming leads and acting on the switch.

Sub-stations and most consumers of any size are, however, usually connected to the circuit by looping a high pressure feeder into them, and then the arrangements have to be more

elaborate. The usual way of doing this is to provide an oil switch, on both the incoming and outgoing feeders. These switches are fitted with automatic cut-outs or protection gear, either of the time-element or the Merz-Price type as already described, the connection to the customer being taken from the conductors joining the switches, which really form bus-bars. This connection should also be provided with an automatic cut-out itself, so that the local installation may be cut off the supply mains, or may be fed from either direction in case of accident.

A great deal depends on the design and proper operation of this switch gear which is rather expensive. One of the most desirable improvements in power supply practice is the standardisation of this class of work, its simplification, and its cheap construction while insuring efficiency.

In most cases the connection work for this purpose in the sub-stations or on customers' premises is carried out with bare copper rods or with cables, and separate pieces of apparatus are assembled for the purpose; but Messrs. Reyrolle and Company who have had the experience of the Newcastle Company to guide them have lately introduced a form of switch gear in which the whole of the arrangements are standardised and rendered very compact.

The chief points about it are:—

1. The omnibus bars and connections are surrounded by solid insulating material poured over them after everything is joined up, which enables the connections to be placed much closer together than if they were in air.

2. The whole gearing and connections are encased in iron which is put to earth and thus any chance of shock is obviated.

3. The switches and instruments are on a movable carriage, so that if anytning goes wrong they can be drawn out at once and replaced by another set while the first set is sent for repairs.

This switch gear is often located close to a wall in a closed room and the switches themselves are arranged so that they can be operated from the other side of the wall.

Electric Energy at the Consumers' Premises.

I have already stated that there are about 600,000 horse-power of motors installed in works in this country, and supplied from public supply stations, while the horse-power of motors driven by private generating plants is probably considerably in excess of 1,000,000. A return just published for the United States puts the motors installed there on similar public circuits at 1,649,000 horse-power in 1907, and as this had increased from 438,000 in 1902 it will be seen that the rate of progress has been equal to 276 per cent. in five years. The United States total is, therefore, about three times that for this country. It is true that the United States population is double ours, but a much larger proportion of the people live in rural districts. Taking this into consideration the use of electric motors in factories supplied from public stations is, therefore, at least double in the United States what it is here, showing the large opening there is for increase in this respect.

I cannot hope to review here the immense field for the employment of electric driving in factories, but on the principle of the greater including the less, I propose to devote a short time to the consideration of electric driving in industries where the adoption of the electric motor has been considered to offer the least advantages.

The industry which has always been considered the most difficult for electric motors to replace mechanical driving has been the textile, particularly cotton-spinning and weaving. Although, however, in mills fitted with modern engines of considerable size, not much gain in actual cost for power may be shown, the advantages of electric driving in other ways are such that it is paying to make the change, and when this is being done the question of whether the supply should be made on the spot, or whether it shall be obtained from a public supply station is largely one of relative cost, and that, as we have seen, is dependent in a great measure, other things being equal, on the scale on which the local supply undertaking can be operated. The great gain in this industry experienced from electric driving is in the first place the regularity of rotation of the motor and its instantaneous response to the imposition of a heavier load. For instance, the three-phase motor ordinarily has a slip of 4 to 3 per cent. when heavily loaded—depending on its size, but the increase of the slip by 1 per cent., which ensures a 1 per cent. fall in the rate of revolution, will probably nearly double the torque which the motor exerts. In machines driven by shafting, not only is there the greater irregularity of the engine, but there is considerable whip or spring in the shafting, and slip of belts when working, and this increases

or decreases as the load varies. In textile work the rate of working is limited by the breaking of threads, and it is obvious that any irregularity when the threads are nearly at their maximum strain will result in rupture. With a more even and steady drive it is found possible to speed up machines 5 or 6 per cent. without incurring more breakages and consequently while increasing but little the cost of attendance.

I cannot afford to devote further time to chronicling examples of the use of electric driving in other industries, but two special applications which are attracting attention at present may be noticed, namely, main haulage for collieries and the driving of rolling mills.

A further interesting development is the design of single phase motors which can be operated from one phase of three phase circuits, and which by movement of the brushes on the commutator of a short circuited armature can be made to vary their speed through a range of some 50 per cent. These are being mechanically coupled to the machine they drive so that the speed can be automatically varied at different stages to suit the operations being conducted. This development of the single-phase motor removes one of the last objections to the employment of alternating currents, namely, the difficulty of providing variable speed motors without excessive expense or undue losses in running at certain speeds.

Probable Developments.

In what I have said so far I have confined myself to what is actually being done now, and I have assumed that progress will be on the lines of present practice, as this is the only safe ground to work on; but when large sums of capital have to be laid out at a time when knowledge is advancing in several parallel fields it is advisable to look ahead to what may be done in perfecting the system of power supply which we are considering, and also to consider whether progress in other directions is likely to alter the situation.

Let us take the last of these points first. When public electric supply is once established, the only conceivable way in which it could be superseded would be by some very cheap and simple form of prime mover operated on the spot. But it is gradually becoming clear that the greatest advantages of power supply from a central source are the regularity of the drive, the fact that scarcely any alteration in the speed of motors is made by throwing heavier loads on them, the gain in the amount of plant required at the station by grouping, and lastly, that with power supply the facilities are always at hand for obtaining an extra amount of power at short notice.

Again, with power supply the customer is put to only small capital expense to obtain his power. For instance, 10 horse-power motors are now procurable, including starting gear, for £3 10s. per horse-power, while 50 horse-power motors, complete with all accessories, will only average about £2 10s. per horse-power, and larger sizes cost even less than this. No small engines situated locally could give these advantages.

Supposing a very simple and cheap running engine were discovered, it would usually have to be connected to a dynamo for works supply, and even if it were used direct its cost would almost certainly be in excess of electric motors, while the attention it would require would be much more.

It is true that there is the alternative of supplying gas for motive power to consumers, but this has the fatal defect of landing the consumer with a heavy capital cost of engines and dynamos, and all the trouble of looking after the plant.

Lastly, if any very simple form of engine were discovered, and one which was cheap to run, the probability is that it could be still more cheaply built and run in large sizes, and would therefore be used in the central station itself.

It must be recollected that the distributing system is very fairly efficient in a well laid-out power undertaking, and the average losses in it ought not to average more than 16 per cent., and probably in future even this will be gradually improved upon as loads become heavier, and networks can be laid out to better advantage. The full load losses again do not average 10 per cent. even now up to the consumer's motor. Moreover, the depreciation of cable systems is very small, while the efficiency of customers' motors is high; whatever changes, therefore, there may be in prime movers, and probably they will be great, it does not seem likely that anything will interfere with the use of electric power in factories, or with its provision by means of distributing systems, such as we have been considering, though these may in themselves be greatly improved in the future.

The position, therefore, is commercially

stable except for this question of prime movers. In this department, steam turbines are for the moment in the ascendant, yet the gas engine is treading on their heels, and the question arises whether it would be better to wait before making developments on a large scale, to see what progress is made in this direction.

The Use of Steam or Gas Plant.

On this point, I would first of all like to say that if changes in prime movers are to be made later in customers' works, or alternately in a central station, it will, looking at the matter in the broadest light, be better to make the change at the central station, because, as we have already seen, probably only half the horse power of plant would require to be changed in the central station that would be necessary if consumers' plants had to be changed, and secondly, the cost per horse-power would undoubtedly be cheaper for large sets than if the horse-power were split up into small sets, situated at consumers' works. The prime mover question therefore is narrowed down to the advisability of using steam plant or of waiting a further development of the gas engine.

Now, I have already discussed the efficiency of steam plant in my last lecture, and I pointed out there that while there is probably not much chance of the efficiency of steam turbines themselves being improved very considerably, yet there is room for some improvement, and that there are still openings for very considerable economies in the boiler-house. On the other hand, if gas engines and producers are to be employed in central stations, there is still a good deal of detail work which must be done on them to render them sufficiently reliable and suitable for the purpose.

Now, the same amount of ingenuity and skill spent on improving turbines, and particularly boilers and their working, would, in my opinion, lead to economies which may, I think, be fairly put in the neighbourhood of 25 per cent. over the best present day practice. These economies are chiefly obtained by :—

1. Savings in banking boilers or firing up.
2. Reduction of radiation losses.
3. Better regulation of air supply.
4. Taking more heat out of the gases, as by use of hot-air supply.
5. Higher degree of super-heat.
6. Improvements in auxiliaries.
7. Further economy in the turbine itself.

It is, I think, quite possible that more than this can actually be done, but it is necessary to bear in mind that increased efficiency is usually accompanied by increased capital cost and complication in working, and after a certain point the burden of these may outweigh an actual gain in efficiency considered by itself.

There is little doubt that boiler-makers and others interested in steam plant will not give up the struggle without considerable efforts in this direction when once the situation becomes seriously threatening, and having regard to the almost ideal conditions under which steam plant can now be operated in large central stations, it is pretty certain that improved economies on the lines indicated will be forthcoming, especially as the working conditions in such stations will be better adapted for practising economy than they are now in the first years of this class of enterprise. Nevertheless, when all is said and done, I think it likely that the internal combustion prime mover may come forward more quickly than seems now probable on the facts of the case themselves, owing to fashion, which has a great influence in these matters. To effect such improvements as we have been contemplating in steam practice will need much energy and perseverance, and the attention of the best minds, extending over a considerable period; but if there arises an idea that any cause is a losing one, there is a great tendency for the best minds to desert it, and for other people to go in for new developments, because they think they are the coming thing. This has already occurred once or twice in the electrical industry, and it is a point to which I would seriously call the attention of manufacturers interested in steam plant. Considerable improvements are to be made in the direction indicated, particularly in the boiler-room, but if their initiation is delayed too long, the time for taking them in hand may have gone by. The chief factor in the situation, therefore, is the development of the internal combustion engine.

Gas Engines and Producers.

Gas engines are now made up to 4,000 horse-power, and when we know that as much as 500,000 horse-power of such engines is being used in Germany alone at the present time, and when we also recollect that the thermal efficiency of these engines is approximately twice that being got out of steam plant at present, many people wonder why they have not already been adopted for central station work to any extent. There are, however, several reasons for this. The great develop-

ment of the use of the gas engines has been in connection with the use of blast furnace gas, a gas which, when it can be obtained, is regular in quality, has already had the impurities extracted from it in the furnace itself, except dust, and is peculiarly suitable for use in such engines.

To produce gas from the ordinary qualities of bituminous coal in a producer and to be sure of obtaining it of even quality, and to free it thoroughly in the cleaning plant afterwards under all circumstances from tarry matter in suspension, is by no means an easy task; in fact the obstacles to the use of large gas engines at the present day lie even more in obtaining thoroughly satisfactory producers and cleaning plant than in the engines themselves. A producer and cleaning plant which will work well on one class of coal cannot be relied upon to give the same results if the coal is changed. If thoroughly satisfactory producers were forthcoming which could be relied upon to give with management of ordinary intelligence an even quality of gas free from impurities under the varying circumstances of a central station load and with varying kinds of coal, it would not be long before we should see the gas engine working in parallel with the steam engine or turbine and taking up the more continuous part of the load in power stations. It is really the producer question which to a considerable extent is holding back the gas engine for central station work, and also the fact that gas plant is more costly than steam to install in large sizes.

Nature of the Economies obtained by the use of Gas Engines.

Let us consider what is likely to be the influence of the use of such engines in central stations assuming they can be employed. If we turn to the Tables of working expenses which I gave in my last lecture, and if each of the different columns is considered it will be found that the only heading under which the use of gas engines would give an advantage is that of coal cost. At present both the labour bill, the cost of oil and stores and the repair bill would probably be considerably increased if gas engines were used, but we will assume that progress will improve matters as regards these items.

Coming then to consider the coal bill, as things stand at present it does not look as if the saving in the quantity of coal used to produce a certain amount of energy would be more than 40 per cent., which at the price of coal taken in the Tables would mean that energy could be supplied from such stations as we are contemplating 10 per cent. cheaper than if steam plant of present-day efficiency were used for ordinary load factors, and about 20 per cent. cheaper where the load was continuous. Against this we have the fact that at present the cost of gas engines and producers, including foundations and buildings, is something like 25 per cent. in excess of the cost of similar steam plant, and when we add to this a larger sum for repairs and for oil and stores, it will be seen that at present the incentive to the central station engineer in districts where coal is cheap to adopt gas plant is not great, and would not make much difference from the consumers' point of view. It must also be recollected that there is a certain reluctance amongst central station engineers to adopt the gas engine, because it is in itself, when coupled to a dynamo working at relatively low speed, an inferior appliance for doing the work with its slow speed and small capacity for overload to the high speed steam engine and more particularly to the steam turbine.

The economy of using the gas engine will of course be much greater in districts such as London and on the banks of the Thames, and in other similar places where much power is used, and where the price of coal is much higher than in the industrial districts near the coalfields, and it is in such localities that the gas engine will no doubt come into use first for central station purposes. As its advantages are greatest when used for the long hour loads it seems certain that it will make its way into central station working for this purpose, being coupled in parallel with steam plant, which latter is better adapted for taking up variations in load, and the large overload capacity of which could be used for carrying on supply in case of temporary failure of the gas engine.

For small stations there is already a strong bias in favour of gas plant or the use of the Diesel oil engines. For larger stations the change from steam to gas driving will only come gradually especially if the possible improvements are made in steam practice, and when it comes it will be introduced at first to supplement steam-driving and to operate in conjunction with it.

It must be acknowledged that owing to the rise in the automobile industry, and for other reasons, an enormous amount of time and attention is being devoted to improving the internal combustion engine, and the chances are

that in the long run it will win the race, as it is impossible to conceive that in these days of advance engineers will remain satisfied with a prime mover which, however perfect mechanically, cannot be made to give a thermal efficiency of much more than 15 per cent. of the energy value of the combustible used.

To adapt the gas engine successfully to central station work, it appears to me that progress must be made on the same lines as those on which it has taken place in the automobile industry, that is by the use of four to six-cylinder high-speed engines, a type of engine which, as a matter of fact, the Westinghouse Company have been making for some time.

While the adoption of the gas engine cannot, from what has been said, make a great difference in the price at which energy can be supplied to ordinary hour consumers in industrial districts, it is worthy of note that a 40 per cent. saving on the coal bill would provide a margin sufficient to increase the sum assigned for distribution as interest on the capital employed by 20 per cent. and thus would give the ordinary shareholder in a company a fair dividend instead of a meagre one, and this of course will be a powerful incentive in securing their adoption, as soon as engineers have sufficient confidence in them.

The adoption of gas engines operated by producer gas is, however, not a step to be taken without very full consideration even after being satisfied with a type of gas engine and producer. The manufacture of producer gas on a large scale must be considered with reference to the site on which it is to be conducted. It is impossible at times to avoid unpleasant odours, and a good deal of tarry liquid is produced from the cleaners, which is intractable, while sanitary authorities object to its being passed into streams or sewers. It must, therefore, be dealt with usually on the spot, and proper arrangements, including a considerable amount of space, are necessary for this. Altogether, as the process is conducted at present, the manufacture of producer gas from bituminous coal is not a thing which can be undertaken in densely populated neighbourhoods without considerable risks of actions for nuisance.

The Legal Position.

It is difficult, especially for a layman, to present in a clear light the present position of matters and the need for reform.

It must be premised that, as the industry of power supply as well as lighting supply necessitates making use of the roads or the crossing of them, it is absolutely subject to legislation which can affect its development and progress to such an extent as to defeat the best engineering and commercial proposals, or delay indefinitely their being carried out, and alternatively may lead to much capital being spent in other directions than the best.

It is therefore peculiarly important that legislation affecting the industry should be well considered and up-to-date, and that it should even if possible anticipate the probable lines of progress.

Method of obtaining Legal Powers.

Notwithstanding this, most people are aware that to obtain powers to give electric supply for lighting, recourse must be had to the system of proceeding by Provisional Order under the Electric Lighting Act of 1882, which was passed when it was considered impracticable to supply electric energy for such purposes to greater distances than half a mile, and when the use of electric energy for other purposes than lighting was hardly thought of seriously. Nevertheless, the lighting Provisional Order is held to cover full powers for power and heat supply, and outside the Power Acts, and a few Acts obtained by the larger local authorities, all electric supply work has so far been done under it. Although, as we have seen, it is now difficult and inadvisable to develop power supply separately, the Power Acts only give power for electric power supply and for lighting to such consumers as take a supply for power.

For lighting any district a Provisional Order must, therefore, be obtained, in addition to any powers obtained under a Power Act. Now, when obtained, such a Provisional Order also covers powers for power supply, so that if the Provisional Order is obtained by third parties it enables competition in power supply to be set up; and, on the other hand, if it is held by a power company, and they do any lighting under it, it is uncertain how far their system may become purchasable under the purchase clause of the Electric Lighting Act unless the two systems of distribution are kept quite separate—a needless expense and complication. There are other difficulties arising out of the Power Acts, such as the impossible scheme of finance forced on them by Parliament, which is so out of date and absolutely unsuited for an undertaking of this character, that it has led to the curious result that, in the

case of most of the power companies, another limited company has had to be formed to hold the Parliamentary company in trust, entailing double registration fees and heavy legal expenses, besides a great deal of unnecessary complication.

Veto of Local Authorities.

Another point is the absolute veto of the local authorities in so many cases without power of appeal to any tribunal, which leads to negotiations being often dragged out to great length, and not infrequently to very desirable developments being entirely blocked. Theoretically the Board of Trade can override this veto in some cases, but they are usually so subservient to local authorities that this theoretical power is of little moment.

The Acts of 1882 to 1888.

The chief legislative obstacle to electric progress in this country at the present time is, however, undoubtedly the Act of 1882, where private enterprise is concerned and the modified purchase clause of 1888. By the Electric Lighting Act the unit area for supply is usually the area of a local authority, whether borough, urban or rural district.

Working of the Act.

In a large number of such areas scattered promiscuously about there are electric undertakings, established in the provinces for the most part, in the hands of the local authorities. Where these are established their vested interests must of course be considered, and it is difficult to alter the conditions under which they were set up, but there are still numbers of towns of moderate size and populous districts scattered over the country where no electric powers exist, and where, if electric supply is to be given, whether by power companies as part of a large system or independently, it can only be done profitably on the basis of a combined power and lighting supply. They are a class of district where the local authorities are unlikely to proceed themselves and yet where a combined lighting and power supply would be of advantage, and comprise many industrial areas. In all these cases the incidence of the purchase clause bears very hardly. I would point out that the terms of this are the same whatsoever the nature of the district to which a Provisional Order relates. The terms of purchase are the same for the companies operating in the richest districts of London and for places in the country where it may barely pay to do lighting at all, although it is to the interest of such districts that lighting supply should be encouraged.

Let us take an example. From the figures it will be seen that the gross revenue of supply undertakings when fully in operation will probably be less than one-fifth of the capital expended, and in the case of lighting the return is often less. That is to say, the capital will only be turned over once in five years at the most. But such undertakings will seldom have their full capacity taken up, and they have nearly always to provide plant in advance of requirements, to meet probable extensions. Again, there are the initial stages while the business is being built up; thus, if we take an average, the capital will in successful undertakings not be turned over probably once in seven years, or six times during the 42 years which constitutes the term of the concession, under a Provisional Order. Now it is very indeterminate what price would be paid in the event of the local authorities purchasing, as they have power to do in the case of Provisional Orders, but I understand legal authorities contemplate that the price to be paid under the purchase clause would not exceed 60 per cent. of the capital of the undertaking. Consequently, besides providing for depreciation and contingencies in the case of power and a lighting supply conducted under a Provisional Order, a fund should be accumulated in addition during the term of the concession totalling 40 per cent. or more of the capital, and this while the capital is only turned over about six times in good districts and probably not more than four or five times in poorer districts.

The Purchase Clause and its Severity.

Now the recent proceedings in Parliament over the London Electric Powers Bills have shown that the terms of the purchase clause are too severe even for wealthy districts, but in the smaller and poorer it is a heavy handicap in addition to other obligations. It is greatly to be desired that for districts below say a certain population or certain rateable value the terms of the concession should be better. If it is not improved it will greatly delay the adoption of lighting in suburban districts and country towns, and in giving them power supply which, while it could be carried out under the Power Acts, would not pay alone.

Length of Procedure.

Again there is the question of procedure under the Provisional Order regulations. When companies apply for orders notice has to be given to the local authorities on the 1st July and the procedure covers a year, the orders being signed usually in May or June of the following year. Thus if the lighting of a district is thought of about Christmas—as is often the case, the desirability of lighting making itself felt about this time—it is necessary to wait eighteen months before an order to proceed can be obtained. The order then comes at a time too late to get plant erected and running by the following winter. Thus it often takes 2 to 2½ years after it has been determined to proceed before an undertaking can get into actual operation, and these long delays and the expenses they occasion take away the incentive to progress, and tire out ordinary commercial men who are accustomed to see some result of their efforts within a year or so.

It is suggested that there is no reason why the Provisional Order procedure should not be assimilated to the light railway procedure which permits application to be made twice in the course of the year.

Foreign Methods of Procedure.

This procedure should be contrasted with that usual abroad, as given for several countries by the lecturer in his paper on overhead transmission before the Institute of Electrical Engineers on February 9th, 1905

In several European countries the procedure is such that if agreement can be come to with the local authorities the whole negotiations need only occupy a few weeks, and in case of disagreement the procedure only occupies three or four months.

Abroad the tendency of legislation is to render private and municipal enterprise mutually helpful. Here, though I believe not intentionally, the result of legislation has been rather to contrast the two and make co-operation difficult.

Conclusion.

In concluding these lectures on Public Power Supply I feel conscious of the fragmentary way in which I have been able to treat a great problem. I have been able to say little or nothing of the application of electric energy to heating, whether in factories, which is having many interesting extensions, or of its use for domestic purposes, a field which is just opening up, or of its probable use in railway working, though the set of figures at which power for these purposes can be supplied may be gathered from the Tables I have given.

However, I think enough has been said to show the magnitude and importance of the supply of electrical energy in the economic, commercial and social life of the future, and my efforts will not have been in vain if what I have said should help to lead our legislators and others to treat the questions which are arising in the working out of this great problem with the attention which it deserves.

THE COAL FIELDS OF TURKEY.

The principal coal fields in Turkey are on the southern Black Sea coast, about one hundred and thirty miles distant from Constantinople, and extend from Heraclea on the west to Filios on the east, a coast line of about forty miles. This coast is precipitous and mountainous, although the maximum height is not more than sixteen hundred feet above the sea level, and is reached at about two and a half miles inland. Near the shore it is not more than two hundred feet above sea level. The whole of these coal-fields are, according to the American Consul-General at Constantinople, Civil List property, permission to work being given only to Ottoman subjects, and even then the Turkish Admiralty reserves the right to purchase sixty per cent. of the amount mined, at a price agreed upon in the mining permit. This sixty per cent. of the total mined can only be sold after having been first offered to the Admiralty, and refused by it. Permits are not transferable without the express sanction of the Government. The Government also claims ten per cent. of the dust. A mine not worked for three months reverts to the Government, which also levies a tax of elevenpence per ton on all coal shipped. This tax can be paid in kind, and the Turkish Government has accepted coal at the rate of ten shillings per ton. The duration of a permit is for no fixed period, but as long as a mine is worked. Some three hundred and ninety-three permits have been delivered up to date, but only about one hundred mines are actually being worked. Permits have been given indiscriminately, and for this reason many were issued at places where it was impossible to work a mine. Some were of no value, and others abandoned owing to the difficulties of transport or lack of capital. The most important of these mines is worked by a French company upon a permit granted to two Ottoman subjects. This company, which has constructed a port and breakwater at Zoungouldak, is the subject of a diplomatic question between the French and Turkish Governments. The French company obtained in the year 1898 from the Turkish Admiralty, which

was at the time of its formation in 1897 entrusted with the administration of these coal-fields, the transfer of the permits to its own name. This transfer was declared illegal by the Sublime Porte, which demanded the re-purchase of these mines. The question has been further complicated by the present company owing to the lack of sufficient capital having influenced the "Régie Générale pour la Construction et Exploitation des Chemins de Fer à Paris," after a year's trial, to undertake the working of its mines from January 1, 1909. This question had every appearance of being settled when the peaceful revolution of July 24, 1908, upset negotiations, and the matter now remains where it was. The output of the Heraclea coal-fields increased from 71,000 tons in 1884 to 625,000 tons in 1907. In ten years from 1884 the output more than doubled, and in the ten years from the formation of the Heraclea Coal Company in 1897 to 1907, it has increased fivefold. This company undertook, when it obtained the transfer of its working permits, to connect the various valleys, Tchatal-Aghazy and Kilimli, with Uzulmes, and Cozlou with Zoungouldak, and also the improvement of the railway line between Cozlou and Kilimli. With this object in view, it has commenced to bore a tunnel between Tchatal-Aghazy and Uzulmes, and on the other side to Kilimli. This work is only about half completed. The company has altogether about ten miles of railway, rolling stock consisting of some 200 trucks and eight locomotives, with which it can handle from four to five thousand tons per day. It has built a port and breakwater, with powerful cranes, and can load between two and three thousand tons per day. Between one hundred and twenty and one hundred and thirty thousand tons of this Black Sea coal are shipped to Constantinople, from twenty to twenty-five thousand tons to Roumania, a considerable quantity to the Ægean Sea, twenty-five thousand tons to Smyrna, and about thirty thousand tons t the Piræus. The company disposes of the largest part of its output to the ships which now coal at Zoungouldak. Besides this well-known coal-field, there are known to exist in Turkey several other fields of importance, but which have never been worked, owing to lack of means of communication and transport. In the same province of Castamouni there is an important field along the coast at Bjide, near Amasra. Three concessions have been granted in this district, but have not been worked for want of capital. At eighteen hours distance from Ineboli there is an anthracite mine, and coal is known to exist in several places in the same district, no attempt being made at working owing to the distance from the sea. In the province of Mamouret-el-Aziz and Diarbekir there are many coal deposits of all qualities, ranging from ordinary lignite to anthracite, but none are worked. In the vilayet of Beyrout there are lignite deposits near the village of Kermaiel, and in the valley of the river Nahr-el Kalb there is a lignite mine yielding five hundred tons, but which is capable of producing ten thousand tons per annum. In the province of Adrianople lignite has been found in the cazas of Dedeagh, Souffli, Ozoum-Keupru, and at Kechan, where a concession has been granted, the preliminary prospecting being found satisfactory, and will now be taken in hand seriously. Permits for prospecting have also been granted for Grisan-Assar, three hours distant from the railway at Xanthi. In the province of Monastir, coal is said to exist in considerable quantities.

THE TRADE OF NICE AND THE RIVIERA.

Nice is such a favourite winter resort for our countrymen, that the recent Foreign Office report on its trade and resources is bound to interest English readers. Its chief commercial asset may be said to be the sunshine of the Alpes Maritimes and Monaco, whence olive oils, celebrated for their purity and fine quality, flowers, and the perfumes of Grasse are exported to the United Kingdom. In respect of oils, though, there has been a falling off, owing to the enforcement of laws against adulteration in France having brought about a great increase of price. As to flowers, during the last two months of 1907 and the first five months of 1908, *i.e.*, from November to May, the total despatched to the United Kingdom from railway stations in the Alpes Maritimes amounted to 2,308 tons in weight; but large as these figures were, there was a falling off, as compared with the figures of the previous year, for two reasons: partly because of the postal authorities having prohibited what used to be the favourite and convenient practice of sending small consignments of flowers to the United Kingdom by post, in sample packets, and partly because the dealers, who send flowers to be disposed of by auction, after arrival in the United Kingdom, are said to have derived little or no profit, and this has had a discouraging effect on florists in the Riviera.

Grasse is said to be, next to Paris, the most important manufactory of perfumes in France. It has been making a brave fight to hold its own against the competition of other countries, particularly Germany, and against the increasing vogue of what may be called chemical perfumes, in contrast to those which are the natural product of flowers. But, in spite of all efforts, the perfumery trade between Grasse and the United Kingdom has sustained a falling off of about 20 per cent. This cannot be attributed to any local cause, but is rather the result of general slackness of trade and widely-diffused depression. Perfumes are luxuries not likely to be much asked for in anxious years. Automobiles are another manufacture in ubiquitous request, and it ought to be possible for British dealers to obtain a larger share than they do at present in the increasing trade of these important aids to locomotion. Seven years ago there were only eight firms dealing in automobiles in Nice; now there

are 45, but not one of the 45 is British or under British management. It is, however, an encouraging fact that whereas French cars were formerly preferred, the United Kingdom is now making up its leeway, and Englishmen in France are using British automobiles. On the water, British motors were still more successful than on land, and at a great competition of motor boats held at Monaco, two British boats were among the winners.

THE AUSTRALIAN MUTTON-BIRD INDUSTRY.

The study of "mutton-birding" is peculiar to many of the small islands about the Tasmanian coast, particularly on the Furneaux group in Bass Straits, where it constitutes the principal means of support of the inhabitants. The "mutton-bird," or sooty petrel, is, when full grown, about the size of the silver gull of North America, and its colour, at first a greyish black, with age becomes a jet black. Their most important breeding places are in the vicinity of Tasmania, and New Zealand; the variety in the latter being somewhat different, and in colour, white, instead of black. The American Consul at Hobart, says that every year, about September 30th, almost to a day, these birds arrive in enormous numbers at their rookeries, and for about a month the male and female birds are busy in restoring their old nests, or in building new ones. When the soil is light and loose the nests are burrowed into the ground close together, but when there is sufficient shrubbery to afford shelter the birds simply deposit their eggs on the bare ground. Frequently large snakes occupy these nests in common with the mutton-birds. As the birds are away at sea in quest of food in the daytime, the nest making is carried on at night. After the nests are prepared, each female lays one egg, which closely resembles a duck egg, and the male and female then take turns at hatching, usually the male bird taking the first turn, while the female goes in search of food, chiefly shrimps, and kelp berries with which she returns each evening. After the lapse of a fortnight, by which time the first sitter has wasted considerably, the partner relieves him, and the male bird will then take upon himself the responsibility of bringing in food. It is not known where the birds go when they leave the islands, about the middle of May. Their flight is extremely swift and irregular, and if the birds strike any obstruction like a rock or the mast of a ship, the collision is usually fatal to them. The lighthouse at Goose Island, one of the Furneaux group, has to be protected with iron screen work, and frequently hundreds of dead birds are found at the base of it. It is only the newly-hatched mutton-birds which have a commercial value, the purposes for which they are taken being for salted human food, for oil (used in tanning leather and for the lubrication of machinery), for the fat used chiefly for greasing timber skids, and for the feathers. The season's work at mutton-birding covers about six weeks, from about April 1 until about the middle of May, when the rookeries are completely deserted. During this six weeks' period, the inhabitants of the islands earn sufficient money to support themselves in practical idleness for the rest of the year. The first stage in mutton-birding is known as oiling. A stick pointed at one end and stuck in the ground at the other serves as a kind of spit or skewer on which to fix the birds as they are caught. Search is then made for the young birds, and as they are caught their necks are broken by a skilful jerk of the hand, and they are then fixed by their beaks to the sticks. It is rather dangerous capturing the birds, as the rookeries are infested with poisonous snakes, and frequently the mutton-birder, when he puts his hand and arm into the hole, lays hold of a snake instead of a bird. When about a couple of hundred birds have been collected, the oil is extracted by squeezing firmly the body of the bird and passing the hand gradually along towards the neck until the oil exudes from the beak. This oil, which is of a reddish colour, has an odour like that of cod-liver oil, and if properly refined it might possibly be used for the same medicinal purposes. There is said to be a number of cases of benefit from mutton-bird diet to persons with pulmonary troubles, anæmia, and other wasting diseases. It takes about one hundred birds to produce one gallon of oil, which sells at from tenpence to one shilling. The next stage in the work is called "fatting," when the birds are first plucked, and then the legs and wings removed; an opening is next made along the back, and the skin with the fat is taken off. The skins, when a considerable number has been obtained, are placed in a large receptacle, and the fat is collected. Next in order is the process of salting. The lower joint of each leg and the outer joint of each wing are thrown away, and the bodies are then salted and packed in barrels in which is placed sea water, and solid brine is then added to make the water still more salt. The birds are then shipped in sailing boats to Launceston, in northern Tasmania, where they sell wholesale at about ten shillings per hundred. About 850,000 birds were shipped to Launceston during last season, and probably about 150,000 birds were retained for the local consumption of the inhabitants of the islands, with whom it is the leading article of food. After reaching Launceston the birds are shipped to other parts of Tasmania, and to Melbourne and Sydney. The market for them appears to be confined exclusively to the Commonwealth of Australia, and chiefly to the mining districts, where fresh food is hard to get, and where the mutton-birds are used as a substitute for salt pork, and a welcome change from tinned meats. The taste for mutton-birds has usually to be acquired, but once people become accustomed to the flavour they seem to grow to like it. The feathers of the mutton-birds, which have a very strong odour, are mostly shipped

to Germany, where, it is understood, a method has been found to rid them of their odour, and render them fit for purposes of bedding. About 25,000 pounds of feathers were exported in 1908, at an average of about three halfpence a pound. About one-half of the inhabitants of the islands where mutton-birding is carried on, are whites, and the remainder half-caste descendants of the aborigines of Tasmania. The mutton-birders are required to pay a Government tax of 10s. for every person above the age of ten years, and half the amount for those under that age, at the beginning of every season. No cattle are permitted upon any Crown lands which are reserved as hunting grounds for the mutton-birds, and taking the eggs of the birds is punishable by fine. Notwithstanding this protection accorded to birds there is indication that their numbers are diminishing year by year, and from four or five of the islands they have already entirely disappeared. The two principal rookeries are at present on Chapel Island and on Babel Island where conditions are most suitable for the burrowing of the birds, and where the best protection has been afforded against depredations by cattle. The number of persons engaged in the industry is about double what it was twenty years ago, and a larger number of birds is taken every year. It is estimated that only about one-third of the young birds escape capture each season on the main rookeries. The Consul states that he has been informed that some of the birds have been shipped alive to Cape Colony, for the purpose, apparently, of ascertaining if they would breed there, but he has obtained no information as to whether the experiment has met with success.

MINES AND QUARRIES.

The General Report on Mines and Quarries for 1908, which has just been issued by the Home Office, contains some interesting information relating to the persons employed in these industries and to the output of minerals.

The total number of persons employed in and about all the mines of the United Kingdom was 1,017,740, of whom 987,813 worked at the 3,338 mines under the Coal Mines Act, and 29,927 at the 721 mines under the Metalliferous Mines Act. Compared with 1907 there is an increase of 47,195 persons at the mines under the Coal Mines Act, and a decrease of 1,675 persons at the mines under the Metalliferous Mines Act. Of the 987,813 persons working at the mines under the Coal Mines Act, 796,329, or 80·6 per cent., were employed below ground. Of the 191,484 surface workers, 6,014, or 3·14 per cent., were females. There is an increase of 364 females as compared with 1907. The number of young persons under 16 employed below ground in these mines was 49,296, or 6·2 per cent. of the underground workers; the total number of surface and underground workers under 16 was 67,435, or 6·83 per cent. of all workers. At the mines under the Metalliferous Mines Act, 17,417 persons, or 58 per cent., worked below ground, and of the 12,510 surface workers, 211, or 1·69 per cent., were females. At the quarries under the Quarries Act there were 85,475 persons employed, of whom 54,449 worked inside the actual pits or excavations, and 31,026 outside. Compared with 1907 there is a decrease of 1,445 among the inside workers, and of 894 among the outside workers, making a total decrease of 2,339 in the number of persons employed at quarries. The persons employed occasionally at quarries are not included in the above figures.

The total output of minerals at the mines under the Coal Mines Act was 275,540,746 tons, of which 261,512,214 were coal, 2,814,411 fireclay, 7,890,814 ironstone, 2,891,564 oil-shale, and 431,743 sundry minerals. Adding 16,581 tons from open quarries, the total output of coal was 261,528,795 tons, which is a decrease of 6,302,167 tons on that of the previous year. The average output of mineral at mines under the Coal Mines Act was 346 tons per person employed underground, a decrease of 26 tons on the preceding year. The total output of minerals at the mines under the Metalliferous Mines Act was 3,128,230 tons, of which 1,549,469 tons were iron ore. The total quantity of stone and other minerals obtained from the quarries under the Quarries Act was 44,732,016 tons, of which 4,801,561 tons were iron ore. Adding to the produce of mines and of quarries over 20 feet deep 789,181 tons obtained from shallow open workings, we arrive at a total output of iron ore of 15,031,025 tons.

THE FIG INDUSTRY OF SMYRNA.

The 1908 production of Smyrna figs has been estimated at about 30 per cent. less than the usual crop, but the quality is exceptionally good, although the size of the fruit is small. Merchants during the year 1908 worked under less restrictions, as far as the importation of the figs into the city of Smyrna from the interior of the country was concerned, than in former years. This restriction in the past has consisted chiefly in the attempt to regulate the number of figs to reach the market, in order to keep prices as high and uniform as possible. The American Consul at Smyrna says that such obstacles have never been placed upon any other product entering Smyrna from the interior of the country. The practice was keenly felt, for the reason that figs packed in two-hundredweight bags, arriving on the market for sale, could not be kept for more than two days, and for every succeeding day they were detained the quality deteriorated about 10 per cent., while their value and available price naturally dropped in proportion. Figs are one of the most important products grown in Asia Minor, and their handling and packing give employment to many thousands of men and women during three or four months of each year. The celebrated fig district in the vilayet of Smyrna is the region about the town of Aidin, on the Smyrna-

Aidin Railway. Fig trees begin to bear fruit in the sixth year, and gradually attain their best period about the tenth year. The trees grown on the Meander plains produce a larger and richer fruit than those nearer the sea or in the uplands in the neighbourhood of Smyrna. This is the case, however, only in normally dry seasons, as too much moisture harms figs, therefore, in off years, or flood years as they are termed in Smyrna, the trees in elevated regions yield a superior fruit to those situated in the lowlands. The wet season highland fig, however, can never attain the delicious taste of a fig which ripens in the plain during a dry season. Figs, as a rule, ripen about the first of August. They fall to the ground after full maturity, are permitted to dry in the sun for a period of six days, after which they are packed into sacks weighing, when full, two hundred and fifty pounds each. One feature of fig-growing which is especially interesting and peculiar is that concerning the male and female figs. Visiting the fig market in the town of Aidin during the month of June, Turkish peasant women from the country were seen engaged in selling only male figs in little baskets. Crawling over the figs were many insects, and upon one of the figs being broken open it was found alive with these insects, which began escaping in every direction. These male figs are purchased by fig-growers in the Smyrna market and hung in bunches on the branches of female fig trees near the growing fruit, which is still very green in the month of June, and about the size of a walnut. The insects from the male figs rapidly collect on the female fig, penetrate the thick skin, and fertilise the fruit. When left in their natural state the process of fecundation is much slower than when thus assisted by hanging a bunch of male figs upon the branches of a female tree. The fruit of a male fig tree is never eaten, and the moment the insects leave, it withers away and rots. In transporting figs to the Smyrna market the greatest care is taken not to bruise the fruit. Sacks are never packed one upon the other. From the orchards in the interior, these sacks are transported upon the backs of camels to the nearest railway station. There are wagons specially built for the fruit, with shelves one above the other, so there is absolutely no danger of pressure or jolting. From the Caravan Bridge railway station at Smyrna they are again transported by camels to the bazaars. The sorting of figs is carried out with the greatest care. They are packed in jars and boxes according to the thickness of the skin and the general size of the fruit. The inferior grades, or the "Hordas," which are little better than refuse, are eliminated from the better qualities and used for distilling purposes. Sometimes figs of this kind are used as a substitute for the chicory root. Although the 1908 fig season, on the whole, was a good one, yet it is doubtful if it was a satisfactory one from a financial point of view, and this applies more especially to the working classes, who in former years made enough money in the three to four months' packing season to live throughout the winter.

ARTS AND CRAFTS.

The New Victoria and Albert Museum.—The opening of the new building of the Victoria and Albert Museum is an event the importance of which, from the point of view of art and craftsmanship, can hardly be over-estimated. A whole generation has grown up grumbling at the arrangement or want of arrangement at South Kensington Museum. If we may judge by what has already been done, when once the collections are arranged in their new home there will be no real cause for complaint. The fact is, that for longer than most of us can remember the Museum has been suffering from an *embarras de richesses* so great that many of its treasures could not be shown, and that the objects on view were so tightly packed together that it was almost impossible to see them. This was particularly evident with regard to the glass and the textiles, where the cases were so close to each other that it was quite difficult to squeeze in between them and go from one to another. One constantly felt, in visiting newer museums on the Continent, that the superiority of their arrangement was due not so much to, say, a German talent for classification, as to the comparative simplicity of the problem which the directors had to face. It is one thing to arrange a small number of objects to the best possible advantage in a new and spacious building, it is quite another and a more difficult matter to show a vast quantity of things in a building far too small to accommodate them properly.

It is, of course, too early to speak confidently of the minor details connected with the arrangement of the new museum. Some of the halls are not yet filled, the new special wall-cases have not arrived, and a few of the rooms have obviously been hastily and only temporarily arranged. But the main plan of the classification is clear. The museum has been systematically arranged with a view, primarily, to the needs of the artist, the craftsman, and the serious student. There is much in it to interest the man in the street, but it is not to him that, in the first instance, it makes its appeal.

The collections are grouped according to industries, such as woodwork, furniture and leather; metalwork; textiles; ceramics, glass and enamels; so that students can conveniently study any special branch of work as a whole, and find examples of the particular technique in which they happen to be interested. This system of classification had, of course, been followed more or less in the old building, but not nearly so wholeheartedly as in the new museum, and the logical completeness of the arrangement is very considerably increased by the inclusion of examples of Eastern handiwork. For some reason or other the India Museum (so called though it embraced Oriental work generally) has always been comparatively little visited, and the inclusion in it of all Eastern work, whether from India, China, Japan, or elsewhere in Asia, not only kept some of our greatest treasures housed in a separate and less-frequented building, but encouraged

the idea that Eastern and Western art were two not merely distinct but totally different things. It is to be hoped that the greater facilities for study in the new building will encourage students of art and handicraft to use the Museum at South Kensington to a far greater extent than they have done heretofore, and that the opportunity of studying European and Eastern work side by side will prove an aid to the appreciation of the unity of art, as well as a lesson in comparative technique. The Indian collection proper, it should be said, seems, in deference to a popular outcry, to have been left in the old galleries on the other side of Exhibition-road.

Craft Work by London County Council Scholars.—The annual show of work by winners of the various scholarships and exhibitions offered by the London County Council for proficiency or promise in art and craftsmanship, took place at the Central School of Arts and Crafts for a couple of days in the middle of the month, and proved one of the most interesting exhibitions of the kind that has been held for many years. It is not that the exhibits are by any means uniformly excellent, though some of them are very good indeed, but that they show so well the general trend of art and craft teaching in London at the present time. This being so, it is not surprising to find that a good deal more attention is being given to certain crafts and, incidentally, to the kind of design in which the worker in them needs to be versed than to pattern design for manufacture. Very little pattern, comparatively, was shown, and not many of the designs were satisfactory. They evinced, moreover, a tendency to imitate Morris in a way more suggestive of parody than of flattery. On the other hand, the woodwork generally, and some of the bookbindings showed a sense of form and a taste which were quite refreshing. Very little carving was shown, and that little was not displayed to advantage, but the simple inlay and cabinet work generally were all that could be desired, and more than could be expected in the matter both of treatment and of accomplishment. Indeed, most of the pieces of furniture on view were such as one would have been only too glad to have seen in one's own house—practical without being cumbersome, and simple without being affected. It is to be hoped that students trained in the technical school to do work like this will have an appreciable influence on the output of their trade.

Amongst the bookcovers there was a small amount of half-binding and other plain work, but they ran, on the whole, to rather elaborate ornamentation. Students in these bookbinding classes no longer design all after one pattern, as though they had all studied under the same master, as they did some years ago. In some cases they have departed from the dignified simplicity which marked this work at its best without arriving at anything better, or, indeed, as satisfactory; but, on the whole, in spite of some blunders in taste, the work is more vigorous and more convincing, more individual one might even say, than it used to be. Some of the script exhibited was beautiful, though students badly want a little drilling in the way to divide their words. *Wal* in one line and *ked* in another, for example, is a division of the word "walked" which ought not to occur in an elaborately illuminated page. There was some good, bold lettering of the sign-writing type, which showed a very marked improvement on the performance of a year or two ago.

Embroidery is always amongst the crafts most largely represented — and in it, too, considerable advance has been made. Not only have the rather trifling little sprig patterns which were the rule given place to quite dainty, though still quite simple, connected pattern, but the general level of technical accomplishment is decidedly higher than it used to be. The prevailing fashion in dress has been eagerly hailed by the schools as affording a chance for the employment of embroidery in connection with dressmaking—and with very happy results.

The exhibition included a certain amount of competent metal-work, though there was less jewellery and enamel-work than we have been accustomed to see. Perhaps the enormous output of more or less artistic jewellery in recent years, and the very low price at which much of it is sold, may, in a measure, account for the falling off.

Taken as a whole, the show marks a decided advance on the part of the schools working in connection with the London County Council.

Fireplaces, &c., at the Agricultural Hall—The Ironmongery and Hardware Exhibition has not, on the whole, very much to do with art. It was rather interesting to note that safes, now-a-days, are enamelled in quite artistic colours, though there has been very little improvement in the colour of the ordinary hot-water can. This last is generally of the yellowish-brown (in imitation of oak graining), with which we have all been familiar from our youth up, and when it is not, it is painted in so-called art shades of a singularly unattractive type. Again, certain by no means beautiful coal boxes, with lids ornamented with blobs of brilliant-coloured enamel, show a lingering remnant of the craze for decorating anything and everything with enamel. But the real interest in the show at the Agricultural Hall from the point of view of industrial art lies in the opportunity of seeing what is being done in the way of grates and fireplaces and the like. And, the scope of the exhibition being commercial rather than artistic, it shows what is normally on the market rather than what can on occasion be achieved. It is, therefore, very satisfactory to see how great has been the improvement in the appearance of the ordinary fireplace in the last couple of years. To begin with, the actual metal-work is much simpler, and in so far, much better than it used to be. There is an absence of the florid cast ornament which used to form a feature of the dining-room grate; and the hoods rendered necessary by the

principles on which modern grates are constructed are far simpler and more graceful in shape than they were a few years back. One very simple, rather Georgian-looking grate was shown by the Bell Foundry Company. Though very plain in design, it was striking on account of the excellence of its proportions. The shape and character of the grates has, naturally, its effect upon the accessories, and the old-fashioned made-up tile surround seems to be yielding either to simple metal sides or to tile panels of "Adams" or such-like patterns, designed especially for their places. The wooden or other mantelpieces surrounding the grates, if not on the whole very remarkable, are at least an improvement on the ornate erections which were so long the fashion.

QUESTIONS AND ANSWERS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

QUESTIONS.

BLEACHING STRAW FOR HATS.—Can any of your readers enlighten me as to best method of bleaching white straw plait? The plait I wish to bleach is from the Palmyra palm leaf. Sulphur does some good, but there are processes in England which are a secret, a certain chemical being used.—CHITTAGONG.

COPRA.—A large quantity of the copra exported to Europe arrives at its destination covered with mould. Is there any treatment by which this can be obviated?—MALAY.

GENERAL NOTES.

MEMORIAL TABLET.—The London County Council have recently affixed to No. 4, Beaumont-street, W., a memorial tablet bearing the inscription:—"John Richard Green, 1837-1883, Historian of the English People, lived here." During the three-and-twenty years which elapsed between his first acceptance of a curacy at St. Barnabas, King-square, Goswell-road, and his death in 1883, John Richard Green occupied numerous residences in London, but the house in Beaumont-street was his home for the longest period, and it was here that he wrote the "Short History of the English People."

INTERNATIONAL FOOD CONGRESS.—The second International Food Congress will be held, under the auspices of the Society of the White Cross of Geneva, in Paris, from October 17th to 24th. The first Congress was held last year at Geneva, and was devoted mainly to definitions of food and alimentary substances. It was well attended, the number of delegates from the 29 countries represented being 400. This year the principal work of the Congress will be to consider the operations and manipulations permissible in connection with food substances, with a view to the repression of adulteration in food, chemical products, drugs, mineral waters, &c., and it is already certain that the number of delegates representing Governments, local authorities and associations will be far larger than that which attended the Congress in 1908. The Society of the White Cross of Geneva was founded last year with the primary object of grouping together by means of international organisation, the efforts being put forth in various countries for the amelioration of social conditions.

TINNING OF METALS.—A Parliamentary paper (Cd. 4740), which has just been issued, contains the draft regulations proposed to be made by the Home Office for factories and workshops in which tinning of metal articles is carried on. They provide that tinning shall be performed under an efficient draught; that no person under 16 years of age shall be employed in tinning; that skimmings from the dipping bath shall not be removed from under the efficient draught until they have been placed in a covered receptacle; and that these, as well as the dust and refuse collected from the floor, shall not be deposited in any room in which work is carried on. A health register containing the names of all persons employed in tinning is to be kept, and every person employed will be examined periodically by a surgeon, who shall have the power of suspension. A cloak-room must be provided for women workers (as well as aprons or other equivalent protection), and a meal-room and a lavatory must be maintained at every tinning works. It is also provided that all persons employed shall wash their hands before partaking of food or leaving the premises, and that no food or alcoholic drink shall be partaken of in any workroom. The regulations will not apply to any process in silver plating, or any process in which a soldering iron is used, or to any other process which may be exempted by the Chief Inspector of Factories on the ground that the regulations are not required. The regulations will come into force on October [illegible] next, except the one relating to the carrying on of tinning under an efficient draught. This will come into operation on April 1 next.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

MODERN METHODS OF ARTIFICIAL ILLUMINATION.

By Leon Gaster, A.M.I.E.E.
(Editor of the *Illuminating Engineer.*)

PART I.*

Introduction.

When I consider the long list of distinguished predecessors who have delivered Cantor lectures before the Society, I need hardly say that I greatly appreciate the honour and privilege of delivering this series on "Modern Methods of Artificial Illumination."

It is, I think, peculiarly fitting that the Royal Society of Arts should take an interest in this subject, for it may truly be said that, in the past, they have encouraged the development and utilisation of all illuminants in an impartial manner such as, perhaps, no other Society in this country can claim to have done. They have invariably presented an opportunity for the discussion of all methods of lighting from the candle to the glow lamp, and many years ago they had already offered prizes for the invention of miners' lamps, lighthouse apparatus, and other practical developments in lighting. Over 100 papers have already been read before the Society dealing with various aspects of the subject with which I am concerned in these lectures.

As early as 1874 Cantor lectures were delivered by Prof. Barff, M.A., on carbon for heating and illuminating purposes. Again, in 1881, Prof. W. Grylls Adams, F.R.S., delivered Cantor lectures on the scientific principles involved in electric lighting, while in 1883 Mr. Leopold Field, F.C.S., lectured on solid and liquid illuminating agents.

The Cantor lectures by Prof. Vivian Lewis on acetylene, and also on the theory of the incandescent mantle, &c., undertaken at a time when these subjects had begun to interest the general public, and Prof. Sylvanus Thompson's exhaustive Cantor lectures on "Arc Lamps," are again illustrations of the enterprising and impartial policy of the Society.

In 1881, Dr. R. Brudenell Carter delivered a series of Cantor lectures on the subject of colour blindness. In that lecture, and in the subsequent valuable communications of the same author on the subject of eyesight, indications are furnished that the Society was early alive to the importance of drawing attention to the preservation of the eyesight of the public, and its important connection with good illumination.

Naturally, in the short time at my disposal, I cannot hope to deal exhaustively with each special department of the subject of illumination so as to furnish information to the expert in his particular line; my aim and object will be rather to cover the ground in a general manner, and to show how it is possible to take an impartial interest in all systems of lighting, and to emphasise the true merits of each illuminant for different purposes.

I may, however, preface my discussion of this subject by a few remarks on the development of illumination in general. The introduction of gas for street lighting for instance, dates from about 100 years ago. Previous to this time we had recourse to oil lamps, and it is even said that bowls of pitch were used to light the streets of Paris in the sixteenth century.

At the same time the use of lamps for interior lighting was likewise in a very primitive state. In those days the expression "The night when no man can work" had a very real significance which we can hardly conceive to-day. Now, in the present age, the tendency is to do more and

* The Course consisted of four lectures, delivered on February 15th and 22nd, and March 1st and 8th. In re-arranging the material for publication in the *Journal*, the lecturer has preferred to divide it into six parts.

more work by artificial light and to turn night into day with an ease our forefathers might or might not have envied, but certainly would have regarded as incredible. Step by step with these developments in lighting have taken place the progress of education and the spread of printed matter, until, to-day, we use our eyes for the purpose of acquiring knowledge to a far greater extent than in the times when neither education nor adequate illumination was generally available.

In the same way the eye is used to a far greater extent in education than was previously the case. No lecture is now considered complete without the exhibition of a few lantern slides, while recently such special appliances as the cinematograph have also been put to the service of education.

We ought, therefore, obviously to consider not only the actual light we produce but its effect under practical conditions—the actual illumination in which we are mainly interested, and for which we are really paying. Expressing the matter epigrammatically we may say "light is the cause, and illumination the effect."

I dwell on these points but briefly in this present lecture, meaning to return to them in greater detail later on, but I would ask you to bear the situation in mind when I go on to mention some other developments in the quality of lighting that have given rise to important changes in industrial conditions. Viewed from this aspect we are bound to realise that illumination is first and last dependent on the physiological impressions from the eye. Into this point, too, I do not wish to enter too closely in the present lecture; it seems, however, a little singular that this obvious fact has not hitherto been very generally realised among engineers, who are at the present time mainly responsible for the generation and distribution of light.

Simultaneously with this enormous progress in the amount of light available has proceeded a remarkable development in our powers of modifying its quality.

Returning to our earlier sources—the camp fire and the charcoal brasier—we see that the light thus obtained was of a distinctly reddish character; afterwards came the pine torches, still very red, then candles and oil lamps, which are whiter. Later still the introduction of gas provided light of a still lighter tint, and, indeed, we have records of objections to it on this score when it was first introduced. The incandescent mantle and the electric light have now provided sources of light that are whiter still.

Now this change in colour corresponds with a very natural development in the temperature of incandescence obtainable, for all the sources named depend for their action on the heating up of solid particles. In civilisation we have passed through a similar process to that which takes place when we heat up a piece of iron. At first we merely obtain a jumble of radiations of long wave lengths, none of them capable of giving rise to the succession of light. As we go on heating we eventually perceive a faint red glow corresponding to the low vibrations, and then this glow develops a yellowish and eventually even a whitish character.

Yet we know that by heating solids in this way, we must always obtain only a confused forced vibration of the mass as a whole, and therefore relatively few rays of the luminous variety. Still more recently, however, we have learned how to employ luminescent gases in which the natural frequency of vibration of the different particles is utilised so that we obtain only vibrations of certain specified frequency, and a corresponding peculiarity in colour, certain rays being often absent, which exist in the normal spectrum of an incandescent solid. An illustration of such methods is afforded by the mercury vapour lamp and the flame arc.

These I mention, merely in order that you may bear in mind that the change in methods of illumination, to which we are now becoming accustomed, is one not only of quantity, but also of quality, and therefore requires correspondingly careful study, in order that we may know how the new conditions may be utilised to the best advantage.

After this preamble, I may now turn to the consideration of recent developments in electric lighting, and I think that a fitting introduction to these new illuminants is provided by the following abstract of Mr. Swinburne's Presidential address before the Institution of Electrical Engineers in 1902:—

"Our chief work, until lately, has been producing light. Here the inefficiency and waste is prodigious, there is still great room for improvement. We take great care over our stations, watching every penny from the coal shovel or mechanical stoker to the station meter. We quarrel over 1 per cent. in the generators. When we get to the mains we care less, and once we get to the customers' meters we care nothing at all."

Since the date of Mr. Swinburne's address we have seen a wonderful development in electrical illuminants. We have seen great

progress in Flame Arcs, Metallic Filament lamps, not to mention the Mercury Vapour lamps, and the Moore Vapour tube.

We have also seen a great change in the method of regarding the utilisation of the light we have been at such pains to produce, and the partial realisation of the true significance of the word "Illumination." As an amusing illustration of this fact let me mention the experience of a friend who had the curiosity to look up the word "illumination" in an encyclopædia. He was rewarded by the cryptic reference, "Illumination—see fireworks."

GLOW LAMPS.

It may seem strange to reflect that from about the year 1878, when the first practical incandescent lamps were introduced, until a few years ago, when metallic filament lamps came upon the scene, the actual construction of the carbon filament lamp should have remained so essentially the same. Yet we must remember that there were wide gaps in our knowledge of the materials available for the manufacture of the filaments of these lamps which have since been utilised so successfully; these gaps had to be bridged before the newer material could be turned to practical account.

In addition, as M. Blondel has shrewdly remarked, there were several misconceptions which inventors did not learn to avoid. It was, for instance, generally supposed that all that was necessary was to find a substance with a very high melting point, and therefore capable of being carried to a very high temperature of incandescence. Actually we know now that this is a desirable quality in filaments, but at the same time we also know that the carbon tends to vapourise at temperatures very far below that at which it actually melts, and it is this tendency which imposes a practical limit on our possible temperature.

By bringing a carbon filament lamp to incandescence at a voltage higher than that at which it was intended, we could obtain a corresponding increase in efficiency, but only at the cost of its durability and life—long before the melting point is reached the volatisation of the carbon sets in and brings the filament to a premature end. What was really wanted, therefore, was a material that only began to vapourise in this way, and therefore to disintegrate at a temperature above that utilised in the carbon filament lamp.

Nernst Lamp. — Regarding the Nernst lamp, which deserves the credit of being one of the earliest commercial attempts to increase the efficiency of incandescent lamps to any great extent (being introduced about 1897), I have not at my disposal any very novel data which can be made public. It may be said, however, that experiments are in progress with the object of making the filament in such a way as to enable it to "light up" more quickly without the necessity of the inconvenient heating coil and its additional complications.

The Electrical Company have now put on the market an improved form of Nernst lamp of specially small design, in which the four parts of the original Nernst lamp, namely, the body, burner, resistance, and globe are now combined into one unit.

The 220 volt lamp is stated to yield 30 candle-power and to consume abont 0·2 ampères, the efficiency being thus about 1·4 watts per candle. Improvements in manufacture enable the lamp to light up in, approximately, 10 to 15 seconds after switching on the current, and the life of individual lamps under normal conditions is stated to be not less than 400 hours. The average life of a burner has, however, been found to exceed 700 hours. I understand that the company undertake to replace free of charge any lamps which are burnt out under the specific period of 400 hours. The lamp is manufactured for all voltages from 200 to 300, but for the present they are only recommended to be used on direct current circuits.

By the kindness of the Electrical Company, however, I am also able to show you to-night one of the most recent developments in these lamps, namely, a 200 volt, 1,000 candle-power lamp utilising three glowers.

The Osmium Lamp, introduced about 1898 by Auer von Welsbach, to whom we also owe the incandescent mantle, is interesting as being one of the first of the commercial metallic filament lamps of recent date. There were, however, many difficulties in its manufacture—notably its brittleness, and the inability to make lamps for higher pressures than 50 volts—which hindered its development, and the lamps have been practically superseded by others to-day.

Filaments of *iridium*, a kindred metal, have been constructed by Gülcher. Here again, however, it seems to have been found very difficult to make lamps for reasonably high pressures, and the use of such filaments seems to be confined to low voltage lamps for accumulators on motor vehicles, &c.

The Tantalum Lamp, as you know, consists of drawn wire composed of the metal Tantalum.

The consumption of the lamps now on the market, of which you will see some illustrations (kindly supplied by Messrs. Siemens and Co., Ltd.), varies from about 1·8 to 2·2 watts by candle.

To this Company also belongs the credit of having produced a 16 candle-power metallic filament lamp working at 100 to 130 volts, and a 32 C.P. lamp on 200-250 volts. I am given to understand that still further developments will follow shortly. The useful life of the lamp under normal conditions can be taken as about 800 hours. I will refer, in a later part of this lecture, to the behaviour of Tantalum filaments on alternating currents circuits.

There have, however, not been wanting experiments having for their object the improvement of the carbon filament lamp.

Graphitised Filaments.—You are probably acquainted with the researches of Mr. Howell in the United States (Proc. Am. I. E. E. 24, p. 617, 1905) who by a special process succeeded in making a so-called graphitised filament capable of giving a satisfactory light at a consumption of 3 watts per candle. The behaviour of these filaments suggests that we are dealing with an allotropic form of carbon in which it approximates to the qualities of a metal having a positive temperature co-efficient under normal conditions. Had it not been for the immense development of the more efficient metallic lamps, this marked advance would have received more attention than it actually has done.

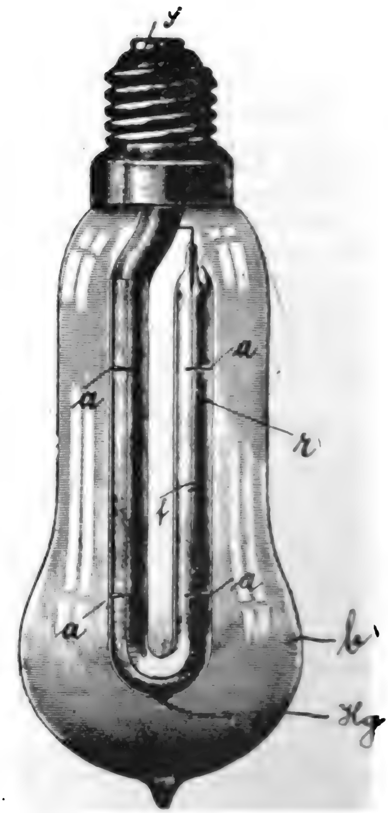
Filaments of Soot, special Carbon Filaments, &c. — Experiments in this direction are still proceeding, and I observe that two German inventors claim to have succeeded in making a peculiarly homogeneous carbon filament from soot produced by the carbonisation of vegetable oils, and also from the materials used in Chinese ink. For this filament a useful life of 1,000 hours with an efficiency of 1 watt per candle (Hefner) is claimed.

The Hopfelt Lamp.—Another interesting attempt to run carbon filaments at an increased efficiency is due to Hopfelt (E.T.Z., Oct. 8th, 1908, *Illuminating Engineer*, vol 1, p. 631) who has utilised a carbon filament burning in an atmosphere of mercury vapour. It is claimed that the high pressure of the latter reduces the tendency to disintegration on the part of the filament, and therefore enables us to run at a consumption in the neighbourhood of 1·5 watts per candle.

It is too early to speak of the possible developments of this method. I have, however, a few here on exhibition in order that you may judge for yourselves.

Since writing the above I observe that a more complete study of this lamp has been published by U. Bordoni ("Atti della Assoc. Ellettrotecnica Italiania," March-April). He, however, describes researches according to which the lamps examined had but a small life.

FIG. 1.



HOPFELT MERCURY-CARBON GLOW LAMP.
f, filament; *a, a, a*, supports for filament; *Hg*, globule of mercury; *b*, outer bulb; *r*, inner tube containing filament.

The Helion Lamp.—An interesting type of lamp is that brought out by Parker and Clark in the United States, termed the "Helion" lamp.

The filament of this lamp is supposed to consist mainly of silicon, which is deposited by a special method on a carbon core. M. Blondel has advanced the suggestion that this may form an eutectic alloy with the carbon (Congrès de Marseille, 1908).

For this lamp it is claimed that a life of over 1,000 hours, at an efficiency of one watt per candle-power, coupled with practically no

diminution in intensity is obtained; at the same time all the advantages of a high resistance filament are said to be secured. More recently still, the inventors claim to have improved the filament sufficiently to enable it to be burned in the ordinary atmospere without any vacuum; they also state that it can be overrun to a very considerable extent without suffering thereby. (*Electrical World*, N.Y., September 5, 1908). In spite of the excellent results recorded, however, we are still waiting for these lamps to be put upon the market on a commercial scale.

Tungsten Lamps. — There are now very many forms of Tungsten lamps on the market. They are called by different names and made by several distinct processes, but although the actual materials are believed to be subject to a slight modification in the case of different firms. it seems to be generally agreed that the metal tungsten is the basis of their composition. The actual processes of their manufacture are, however, extremely complicated, and I cannot hope to attempt to describe them on this occasion.

I should, however, like to refer to those who desire more complete details to a recent paper by M. Blondel (Congrès de Marseille, 1908) and to articles by Dr. H. Weber and Dr. Jacobsohn (*Illuminating Engineer*, London, vol. i., pages 297, 395, 463), in which some very complete data are given. It may, however, be said that there are at least three distinct chief processes. According to the first the metal is reduced to an "impalpable" powder, mixed with some adhesive binding material, and squirted through a very fine die. Subsequently all traces of the foreign binding material are very carefully removed, leaving only the pure metal, the filament being also brought, by a special process, from the non-conducting into the conducting state.

It is wonderful that such good results should have already been accomplished when we consider that filaments so made really consist of a collection of fine disjointed particles fused together.

Another process consists in the deposition of tungsten upon a carbon filament which is brought about by incandescence in an atmosphere of volatile tungsten compounds so that the tungsten gradually replaces the carbon; subsequently by special processes, the last traces of carbon are removed.

Yet another process is the well-known colloidal process of Kuzel, according to which metals are reduced to a special gelatinous condition, such that they can be squirted into filaments without the admixture of a binding material; in this way the arduous process of subsequently removing all traces of impurity introduced are avoided. These lamps have been sold in Vienna under the name of "Sirius," and are to-day sold in London by Messrs. Falk, Stadelmann and Co., Ltd., as the "Sirius-Effesca" lamp.

Although we must admit that most of these methods originated in Germany and Austria, we can comfort ourselves with the reflection that much of the early pioneer work of electrical glow lamps was carried out in London. At the present day too, I am happy to state that the manufacture of these lamps is being taken up in the country. To-night there are on exhibition different types of metallic filament lamps as supplied by Messrs. Boddy and Co. (the Metallik), The Bryant Trading Syndicate, The British Thomson-Houston Co., The Edison and Swan United Electric Light Co., The Electrical Co. (Aegma), Messrs. Falk and Stadelmann, Ltd. (Sirius-Effesca), the General Electric Co. (Osram), The Stearn Electric Co., The Sunbeam, the Westinghouse Co., and the "Z" Electrical Syndicate. Lamps are also sold under the following names, among others, in this country: — Simplex, Meta, Empire, E.M.F., Gral, Z., Auriga, Metfil, Tangent, Metalite, Rugby, Gabriel, Solium, Omega, &c. This will serve to furnish some idea of the choice of lamps available, some of which are now manufactured entirely in this country.

Some qualities of the metal filament lamps of interest are those given by Remané ("Verb. Deutsch. Elektrot.," 1908), and by Satori in a recent article in the *Illuminating Engineer* (Vol. II., p. 386).

As you will understand from these curves (see Fig. 2), there is no physical impossibility in obtaininga consumption of even less than 1 watt per candle-power from the ordinary carbon filament; but you will also observe how rapidly its life is decreased by doing so. The same holds good for the Tungsten lamp, as this diagram clearly shows. It is, however, worth knowing that now that carbon filament lamps are so cheap compared with the most efficient metallic ones, it may sometimes be advisable to overrun them intentionally at, say, 2·5 watts per candle, so as to obtain a higher efficiency, even coupled with a loss of life. This point has been dwelt upon by the correspondent of the *Illuminating Engineer* (Vol. I., December, 1908, Vol. II., January and February, 1909).

But let us ask ourselves what disadvantages the new lamps already possess, and what prospects of improvement we see before us. In reality, when one follows closely the immense technical difficulties with which the manufacturers of metallic filament lamps have been confronted, one can only marvel at the ingenuity with which they have overcome obstacle after obstacle. One of the main problems has been, and is still, the production of a metallic filment lamp of high voltage and low candle-power.

Thus the production of a Tantalum 220 volt 50 candle-power lamp is said to involve the use of wire of a diameter of only 0·04 m/m, and it is a miracle of ingenuity to draw homogeneous wire so fine. Yet Tantalum 250 volt 32 candle-power lamps are already on the market.

An Osram 220 volt 50 candle-power lamp involves a filament of the same order of diameter, coupled in both cases with an extraordinary length of filament.

Several lamp makers now announce that they are in a position to supply 200-260 volt lamps of as low a candle-power as 25-30 candles.

In the United States a 25 watt 100 volt Tungsten lamp has already been produced. As an illustration of the difficulty of this process I may mention that it takes a man a week's careful work even to make the die through which such filaments are forced.

FIG. 2.

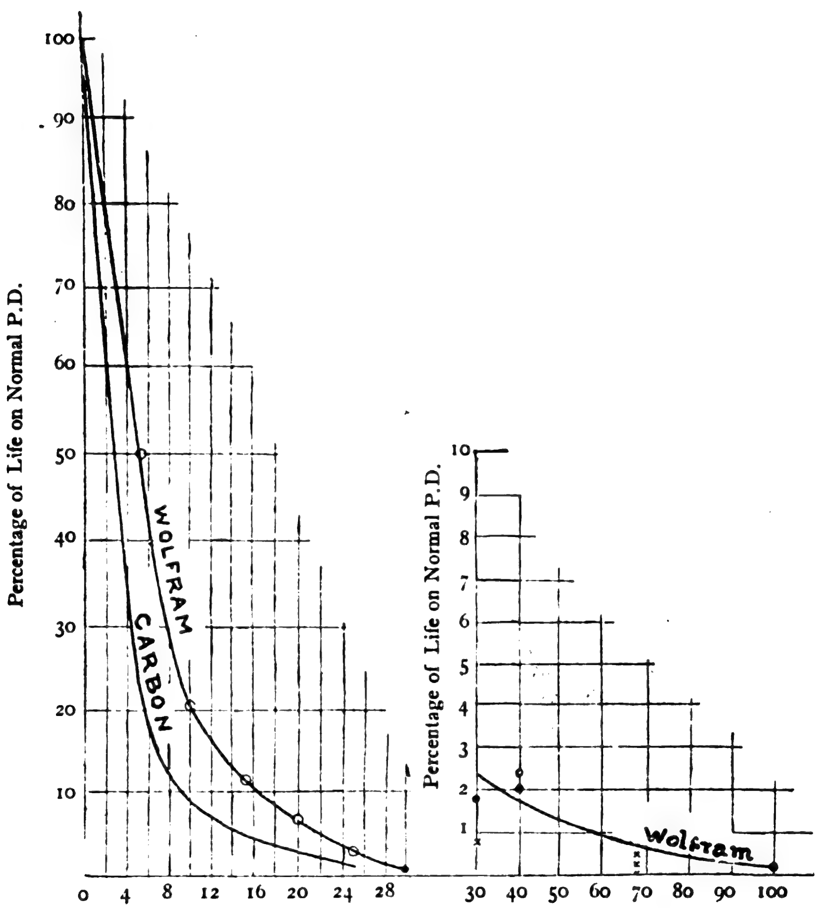


DIAGRAM ILLUSTRATING EFFECT ON LIFE OF OVERRUNNING CARBON AND TUNGSTEN FILAMENT LAMPS. (Satori, *Illum. Eng.*, London, Vol. II. June, p. 386.)

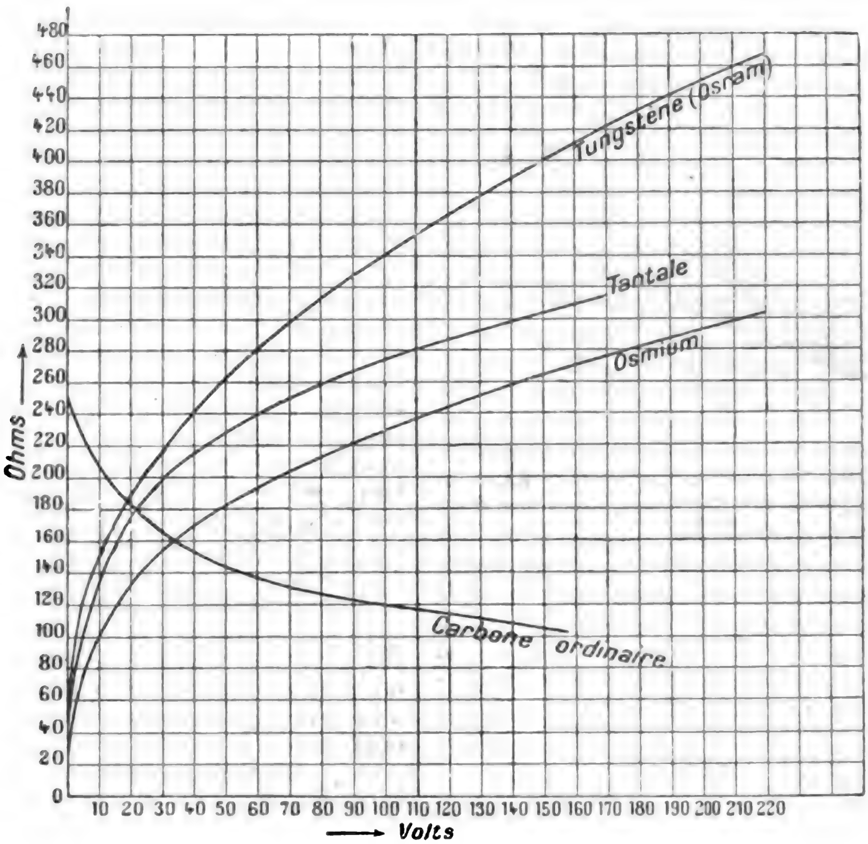
Since the delivery of this lecture I notice that several makers have already brought into the market 16 candle-power, 100-130 volts metallic filament lamps rated at a consumption between 1 and 1½ watts per candle. Indeed, within the last few weeks the announcement

has been made that the Stearn Co. are producing a 200 volt, 16 candle-power, 25 watt lamp. Simultaneously with the improvement in this respect a great reduction in the price has also taken place. I cannot help feeling, as I have already previously pointed out, that it would have been far better if manufacturers devoted their efforts to improving the lamps they have already put on the market, instead of expending misplaced energy in cutting now about the same size as those of carbon filament lamps, so that the original fittings and shades can be used upon replacing carbon lamps by these new types.

The difficulty in making high voltage low candle-power metallic filament lamps rests, of course, mainly in the very low resistance of the filaments compared with carbon. Yet, from one point of view this defect may be regarded as fortunate because of the extremely disturbing

FIG. 3.



CONNECTION BETWEEN RESISTANCE AND PRESSURE OF CARBON FILAMENT TANTALUM, OSMIUM, AND TUNGSTEN LAMPS. (Blondel, Congrès de Marseille, 1908.)

one another's prices. If by the united action of lamp makers and dealers the prices were kept at a steady figure, giving a substantial margin of profit, funds would then be available for adequate experiments with the object of improving the quality of lamps. Progress will naturally be hindered by forcing the pace and supplying an indifferent article simply to meet competition.

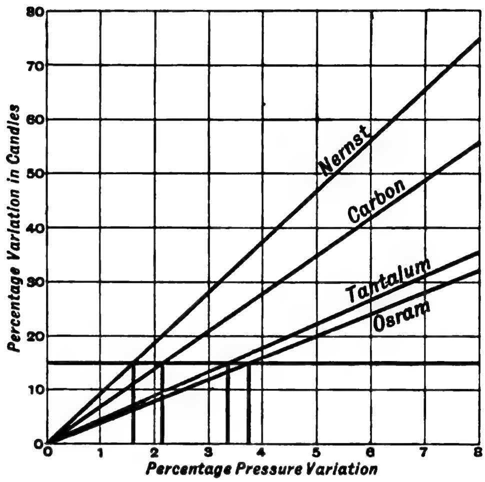
It is also gratifying to observe that the bulbs of some types of metallic filament lamps are effect upon the electric industry which would follow the sudden introduction of, say, Tungsten lamps capable of giving only eight candle-power at one watt per candle at 250 volts.

As I have pointed out previously, the present state of things serves to enable us to tide over the inconvenient transition.

Another quality for which metallic filament lamps are remarkable is the fact that their resistance, unlike that of carbon, increases with temperature; this is indicated in Fig. 3.

Partially owing to this change in resistance we find that a given change in pressure produces a smaller corresponding change in candle-power in the case of metallic filament lamps than in the case of carbon ones. This is advantageous because it may enable the amount of copper in a consumer's leads to be reduced since the thickness of such leads is determined by the fall in pressure allowable up to lamps. (Fig. 4.) Some details of the behaviour of different types of lamps in this way is shown in Fig. 4 and Table I.

Fig. 4.



VARIATION IN CANDLE-POWER DUE TO A GIVEN VARIATION IN P.D. FOR CARBON AND METALLIC FILAMENT LAMPS. (Bohle, *Illum. Eng.*, London, Vol. 1, p. 738.)

TABLE I.

Type of Lamp.	Percentage change in candle-power due to 1 per cent. change in P.D.

Osmium	4·2	..	..	..	..
Tungsten ..	4·0	3·36–3·65	4·0	3·8	4·0

(Blondel, Congrès de Marseille, 1908.)

Percentage change in candle-power due to 1 per cent. change in P.D. in the case of carbon, graphitised, Nernst, and metallic filaments.

On the other hand there is a second effect to be considered. Metallic filament lamps have a lower specific heat than carbon ones and consequently the filaments grow hot and cold with greater rapidity. As a result their momentary physical condition fluctuates to a greater extent when the voltage applied to their terminals varies and, possibly on this account, metallic filament lamps do not give quite such good results on alternating currents as on direct currents. The Tantalum lamp, as is well known, has not as yet been much employed with success on an alternating current circuit. I have been informed by Dr. Feuerlein that this is to be attributed (among other effects) to the attractive action of adjacent filaments on one another.

This gives rise to a continual mechanical trembling, and Tantalum has a property, common to the iron group of metals, of rapidly becoming crystalline under these conditions.

Some experiments recently published by Scarpa ("Atti della Assoc. Elettrotecnica Italiana," January-February, 1909), seem to be in agreement with this suggestion.

I am informed that experiments are being carried out as a result of which it is hoped to overcome this defect. But at the present moment the makers do not recommend these lamps for alternating current circuits at the same efficiencies as for direct current.

An interesting result following from the decrease in resistance of metallic filaments with increasing temperature becomes evident at the moment the lamp is switched on. In the case of a carbon lamp the initial value of the current is much lower than its final value, and we see a lamp gradually light up if it be one of high candle-power.

On the other hand, in the case of a Tungsten lamp the starting resistance is much lower, say, only one-eighth of its final value, and the instantaneous current is, therefore, eight times as high. This is illustrated by the tracings of some oscillograph curves recently obtained by Freeman (*Elec. World*, N.Y., Aug 15th, 1908) and Professor J. T. Morris (*Electrician*, June 7th, 1907), showing the rapid variation of current in a carbon or metallic filament lamp before it obtains its final value. The difference in behaviour of a carbon and Tungsten lamp is, therefore, marked, and it has been suggested that the occasional habit of metallic filament lamps of burning out the moment they are switched on is due to this effect.

One interesting type of lamp recently brought out in Germany contains a small carbon fila-

ment in series with the main Tungsten filament (see B. Duschnitz, *Illuminating Engineer*, Vol. I., page 817). This is shown in Fig. 6.

By this means the inconveniences resulting from being obliged to make a filament perhaps a thousand millimetres long and 0·03 millimetres in diameter, as is necessary in the case of a 220 volt 32 candle-power lamp, are partially avoided, for the small carbon filament supplies the required resistance and enables us to secure a lamp which consumes about 1·5 watts per candle, and yet absorbs less actual current than the 16 candle-power carbon filament lamp.

An incidental advantage in these lamps is that the high cold resistance of the carbon filament prevents the initial rush of current characteristic of metallic filament lamps to some extent, the instantaneous current, during switching on, being only twice its final value.

Fig. 5.

—Oscillogram of Starting Current in 220 v. 5 c.p. Carbon Filament Lamp.

Illustrating Growth of Current through Carbon and Tungsten Filament Lamps when Switched on. (Prof. J. T. Morris, *Electrician*, June 7th, 1907.)

This lamp I have here on exhibition. (Fig. 6, p. 766.)

Transformers.—The mention of this lamp brings to mind another development in metallic filament lighting which has caused considerable interest, namely, the use of Tungsten lamps with a transformer. If an alternating current P.D. of, say, 200 volts be transformed down to

25 we are enabled to get all the advantages of the short and stout low voltage Tungsten lamp, the metallic filament being peculiarly well adapted for low voltages, and we have also the incidental advantage of much greater safety.

On the other hand, this system certainly can not be applied indiscriminately, partly because of the high initial cost of the transformer and expense entailed in the substitution of lamps of the lower P.D., and partly because it is very wasteful to have a transformer in action continuously if only a few lamps are switched on. These drawbacks have been to some extent got over by the introduction of automatic switches which cut the transformer out when no lamps are on the circuit. M. Weissman has also

FIG. 6.

THE "ECONO" LAMP.

recently developed the method of applying a small transformer to a special group of lamps, so that it is switched on only when the lamps are switched on, and is, therefore, always working at its highest efficiency.

This system has much to recommend it, and has been found particularly acceptable in the case of lighting illuminated signs outlined in glow lamps, for in this case it is often immaterial whether we have a 2 candle-power or a 16 candle-power lamp on, and lamps and transformer can be switched on together.

Recently the Rheinisch-Westfalische Elektro-Sparlicht Gesellschaft (Essen, Germany) have put on the market a small transformer and lamp in one unit. By this arrangement each individual point is worked at the highest efficiency. The transformers are constructed to take only one size of lamp, and this non-interchangeability makes it impossible to place a bigger or smaller lamp in the same socket. The introduction of this combined unit has much in its favour in those localities in which electricity is supplied, at a fixed charge per point installed in the building. The above system enables central stations to keep a control over a consumer who might otherwise try to change the size of the lamp for which he is charged for one of a higher candle-power. However, it remains to be seen how far progress in the direction of making high voltage low candle-power lamps will render the use of transformers superfluous.

Other Drawbacks of Metallic Filament Lamps. — There are still a number of defects of more or less consequence affecting the Tungsten lamps. For instance, it must be realised that the fragile nature of their filaments, and the large number of breakages that sometimes occur in transport in consequence are very inconvenient.

In addition, one occasionally finds an exceptional and badly manufactured lamp that blackens very prematurely. It is consoling to learn from a recent utterance of Mr. Hirst (Institute of Electrical Engineers, 1908) that manufacturers are prepared to replace lamps that admittedly fail in this way.

And lastly, I may refer to one difficulty, arising from the great length of the filament in the case of metallic lamps, with which most of you are doubtless familiar, namely, the difficulty of making such lamps burn in any but a vertical hanging position. At one time it was found that any lamp burned in a horizontal or even an inclined position suffered because the filaments softened with increasing temperature, tended to sag, and ultimately came in contact and raised a short circuit. An allied difficulty was due to the fact that the expansion of such a length of filament tended to wrench it away from its support.

Both these effects have been to a large extent remedied by the "Z" and other companies by providing a spring loop capable of taking up this additional sag, and retaining the filament in its correct rigid position. To day lamps for 200 volts capable of burning in any position can be obtained. I will now throw upon the screen the actual filaments of several types of lamps, and you will see how the sag, occurring when the current is switched on, is taken up in the various cases.

I have dwelt upon the subject of glow lamps as far as time permits me to do on the present occasion; for further details I can only invite you to inspect the actual specimens on exhibition, and to make enquiries of the

representatives of the various makes who are present to-night.

Conditions of Lamp Industry in the United States as compared with those in this country.

Before leaving the subject, however, I would like to comment on one respect in which the practice in the United States differs very greatly from that in this country. Over here we have, as you know, many quite distinct makers, but mostly importers and dealers of lamps all competing against one another, and all claiming very special and peculiar merits for the particular types of lamps they represent. At the same time we have central stations all over the country employing a marvellous variety of pressures and other conditions of supply, and feeling very dubious as to the exact influence of the introduction of the new lamps on their revenue. The natural result has been that the central stations and the metallic lamp manufacturers do not co-operate to any extent and do not work in harmony. A particular illustration of this is furnished by the difference in the pressure at the consumer's terminals even in large districts in London. It is not only that the declared pressure varies, but it is also a fact that the latitude which the central stations allow in this nominal voltage also fluctuates very greatly.

Permissible Variation in P.D. at Consumer's Terminals.

The voltage, for instance, may be nominally 200, and yet actual records may show that it is near 210 or even 220 during a section of the night, and this notwithstanding the fact that it is clearly laid down by law that the pressure at the consumer's terminals should not fluctuate by more than plus or minus 4 per cent.

It need hardly be pointed out how unfair this is to the lamp maker, who, if he supplies lamps correctly graduated to suit nominal voltage, soon finds that the life of the lamps supplied gives rise to much complaint.

At a recent meeting of the Institution of Electrical Engineers (discussion of Paper by Mr. C. Paterson, 1907) one of the speakers commented on this difficulty, and let us into a secret of one method of trying to meet it—which will receive our sympathy, if certainly not our entire commendation—of supplying lamps marked for the nominal voltage, but really suited to the average actual value likely to occur in that district.

Instances of Co-operation in the United States.

In this connection I would like to draw your attention to the work of the National Electric Light Association in the United States. All the chief lamp makers in that country, who are, however, comparatively few in number, belong to this Association, which supports a laboratory for the purpose of carrying out common tests on glow lamps for the common benefit. In addition, the lamp makers are in constant co-operation with the central station who, indeed, very generally actually supply lamps to their customers, and who, therefore, are in a position to advise them also as to the best means of employing such lamps in their houses.

The recognition by the National Electric Lamp Association of the value of scientific study is exemplified by the fact that the Association has now installed and proposes to maintain at considerable cost, a special laboratory for the study of illumination from the joint standpoint of the ophthalmist and physicist. It is anticipated that much good work will be undertaken at this laboratory for the benefit of the general public and the lighting industry. This splendid example I would like to see imitated in this country.

Another striking example of co-operation between central station lamp manufacturer and consumer is afforded by the action of the Boston Edison Electric Illuminating Co., to whom belongs the honour of being the first supply company to organise an expert staff of illuminating engineers, from whose advice company and consumer alike could benefit.

During the three months that have elapsed since the inauguration of this department under the supervision of Dr. Louis Bell, the President of the Illuminating Engineering Society in the United States, no fewer than 450 applications for assistance have been received from customers, and advice was given free. It is also interesting to know that this number included no less than 19 churches.

We commend to the electric lighting industry of this country the far-seeing policy of our neighbours in the United States.

Another aspect of this question which is causing some anxiety to those in a position to know is the approach of a wholesale reduction in prices of lamps, coupled with the accompanying danger that a large number of cheap but inferior lamps may be put upon the market in this country (possibly the discarded examples of lamps used abroad), just as

happened when the carbon filament lamp was first developed.

The Need for a Standard Specification.

We have now a standard specification by which the consumer may profit if he chooses to do so, while buying carbon filament lamps. Some experiments in this direction have been made in Germany, having for their object the framing of a similar standard specification to be applied to metallic filament lamps, and I understand that attention is being devoted to the matter by the National Physical Laboratory in this country. In any case the time is coming when the desirability of such a standard will be very keenly felt. The great difficulty, however, in drafting a specification and in giving it practical effect lies in the fluctuation in the conditions to which the lamps may be subjected.

As explained above, we may mark on a lamp the conditions with which it ought to comply when properly treated; but, when it is placed on a circuit on which the voltage is only nominally and not actually that marked on the lamp, we shall, naturally, not obtain the results that compliance with the specification is supposed to secure.

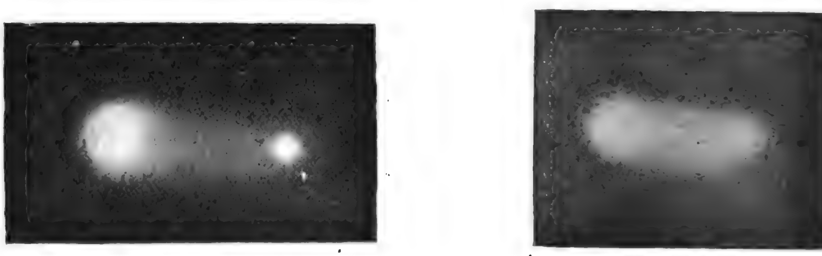
Arc Lamps.

In turning to the subject of arc lamps, I am again impressed by the extent of the material at my disposal, and the short time in which to make reference to the subject. Naturally, my remarks can only be very general, and I cannot enter into details of mechanism but only into general principles.

Two of the main factors of the old open carbon arc lamp on which attention has been concentrated, have been the luminous efficiency of the carbons and their life. We can, of course, always increase the efficiency of a carbon arc by reducing the diameter of the carbons, and so securing a higher temperature of incandescence. But by so doing we also increase their rate of burning away correspondingly.

In the ordinary carbon arc, as you are doubtless aware, the great majority of the light is thrown from a white hot incandescent spot of a positive carbon which we call the crater; the light from the arc itself, and even from the negative carbon, is relatively small. We have, therefore, to deal essentially with thermal radiation of an incandescent solid, and under these conditions the luminous efficiency is bound to be small because we produce a mere jumble of vibrations in which heat waves which are useless from the luminous point of view, predominate.

Fig. 7.



Ordinary Arc. Flame Arc.

Illustrating the appearance of Arcs between Ordinary and Flame Carbons respectively.
(Andrews, Inst. of Elec. Engineers, 1906.)

Incandescent Vapours.—Recourse has therefore, been had to a second possible wa of increasing efficiency, namely, by the use c the principle of luminescence and the fre natural vibrations of a vapour instead of solid. This was accomplished by introducin a suitable volatile chemical substance into th carbons.

Flame Carbons.—Many attempts were mad in this direction, both in the direction of im pregnating the carbons with a solution, and i providing them with a suitable chemical core

Under these conditions it was found to b possible to obtain a bridge of highly luminou vapour, from which the greater portion of a ligl is received. There were, however, many diffi culties in the application of this principle. F instance, the early carbons were not sufficientl homogeneous and burnt with a flickering ligh In addition the chemical materials tended t

form a fusible non-conducting slag on the top of the carbons which interrupted the action of the arc.

This last difficulty was largely overcome by the introduction of inclined carbons.

Fig. 7, which represents some date given by Mr. Leonard Andrews in a paper before the Institution of Electrical Engineers three years ago, makes clear the difference in the nature of the arc between pure carbon electrodes and the flame arc. In the latter case the vapour is a source of light, and in addition it is necessary to use a much longer arc of perhaps as large as three-quarters to one inch in length. Under these conditions we avoid the shadow from the negative carbon, characteristic of ordinary arc lamps, and thus save a considerable amount of light that would otherwise be wasted.

On the other hand, it has been pointed out that the distribution of light so secured is unfavourable for street lighting and, therefore, M. Blondel has recently brought out a patent type of carbons which enables a highly efficient white arc to be obtained between vertical electrodes. Carbons of this type are utilised in the Crompton-Blondel arc. (Fig. 8.)

The efficiency of a flame arc is far greater than that attained by the old type, reaching, under favourable conditions, as much as 0·2 watts per candle-power (M.S.C.P. naked arc). Some recent figures of Professor Morris on this subject are presented in the following table:—

Efficiency of Various Types of Carbons and Arc Lamps.

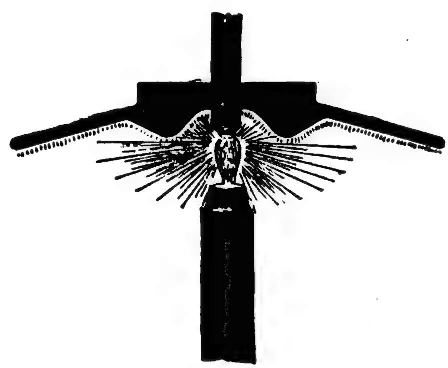
(Morris, *Illuminating Engineer*, Sept., 1908).

	M.S.C.P. per Watt.
Carbons.	
High Grade Flame Carbons ..	2·9 to 3·3
Lower Grade ,, ,, ..	1·5 to 2·5
Ordinary Carbons Open	About 1
,, ,, Enclosed ..	About 0·6
Lamps.	
Lamp with High Grade Flame Carbons Enclosed	3·9
Ditto Open	3·5 to 3·7
Lamp with Auer Carbons	2·5
Lamp with Lower Grade Flame Carbons	1·4 to 2·5
Lamp with ordinary Carbons Open	About 1
,, ,, ,, Enclosed	About 0·75

Since the first commercial introduction of a successful flame by Bremer, many different types of flame lamps have been evolved. I can only make passing reference to a few of these, such as the Excello, Crompton-Blondel, Gilbert, Oliver, &c. The essential characteristic of all flame lamps is that the light is mainly, though not entirely, derived from luminescent vapour.

Efforts to Increase Burning-hours of Flame Carbons.—Even in the case of flame arcs, however, the gain in the efficiency was only secured with an accompanying increase in the rapidity of the wasting away of the carbons. Enormous candle-powers were obtained, but the first lamps produced only burnt for about six hours without re-carboning, and even so extremely long carbons had to be used, thus making the overall length of the lamp inconveniently large.

Fig. 8.



The Crompton-Blondel Arc.

Oliver Magazine Lamp.—The design of flame carbons has got over this difficulty to some extent, but only partially. An ingenious method of meeting the difficulty was that adopted in magazine flame lamps, of which the Oliver lamp was an example. In this case a succession of carbons is stored within the lamp, and the wasted carbon being automatically replaced is thus used up. Evidently a lamp on this principle can burn for a considerable time without re-carboning. On the other hand, mechanism of this type is inclined to get out of order.

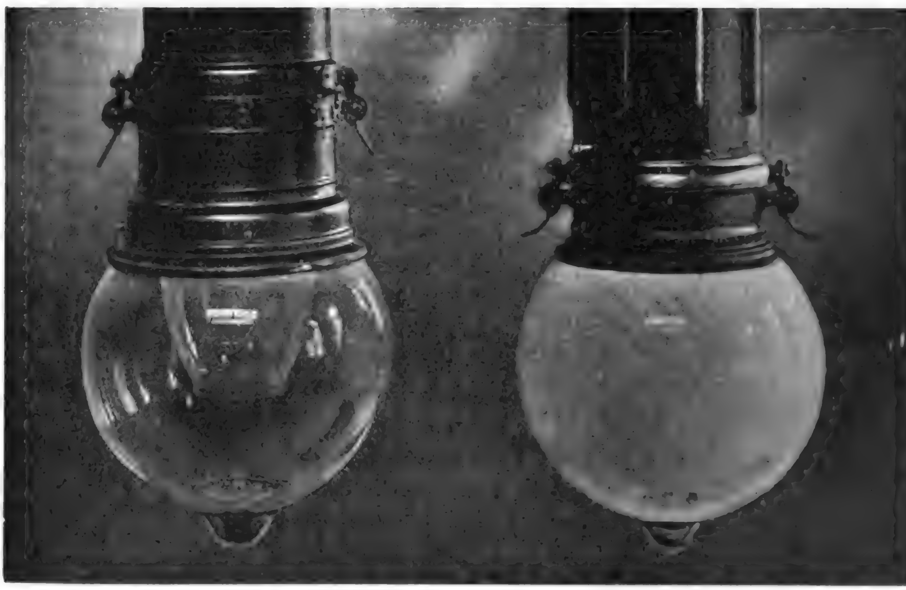
Enclosed Flame Arc Lamp.—It might naturally have been supposed that an attempt would be made to enclose flame lamps as had been done successfully in the case of the arc between pure carbons. In the United States in particular, where labour is dear, lamps of this type had had a great success. Unfortunately the deposition of fumes on the globe of the lamp and the quickly increasing opacity as a consequence, and also the fact that the efficiency of most flame carbons was

considerably diminished when air was excluded, prevented this plan being feasible. Indeed, the condensation of fumes inside the globe has been found to be a defect in most flame arc lamps of the ordinary variety.

More recently, however, a modification has been made by the Union Electric Company in the Excello lamp, involving the introduction of an inner globe, which causes the fumes to be carried away and condensed elsewhere; the same firm utilise a type of inner globe which, being prismatic, serves the purpose of modifying the natural curve of light moved and very long burning hours are secured. A general view of this lamp is shown in Fig. 10, p. 771.)

Lamps with Metallic Electrodes.—Another distinct direction in which the researches of arc lamps have progressed during recent years has been towards the complete replacing of carbons by metallic electrodes. Ladoff, Blondel, and others have done much work in this direction. The best known commercial type of lamp dependent on this principle, however, is the magnetite arc brought out by the General Electric Company in the United States.

Fig. 9.



Excello Deposit-Free Globe.
Appearance of ordinary and deposit-free cover after 100 hours burning.

distribution, so as to render it convenient for street lighting.

Two pairs of carbons burning consecutively are also used, and this is said to enable the lamps to burn for 34 hours without re-carboning; in a very still atmosphere as much as 42 hours has even been obtained. It is also stated that the efficiency of this lamp is of the order of 0·17 watts per M.H.C.P. In Fig. 9 will be seen the appearance of the globes of two identical lamps, one fitted with ordinary globe and the other with the new deposit free type, after 100 hours burning.

Very recently, too, Mr. Denman Jones has brought out a type of enclosed flame arc, by the aid of which the gases are completely re-

This lamp utilises a negative electrode composed of a suitable mixture of magnetite and oxides of the rare metal titanium and other substances. A very long luminous arc is obtained, the quality of which, however, depends entirely on the constitution of the negative electrode. The positive electrode merely consists of a slab of copper. It has no influence on the quality of the light, nor does it waste away. The negative, however, wastes away at such a slow rate that the lamp, it is said, can be burnt 500 hours without re-carboning.

It is also said that the quality of the light, unlike that from most flame carbons, is extremely white; also that it is good for geographical purposes. (It is interesting to observe that the

lamp has just been adopted for the street-lighting of Boston, as the result of exhaustive tests by the authorities in that city.) This, therefore, represents a departure in the direction of securing efficiency coupled with long life.

Miniature Arc Lamps. — Before leaving the subject of arc lamps, reference may, perhaps, be made to one other interesting development in arc lighting, namely, the introduction of miniature enclosed arc lamps taking a small current of perhaps 1-2 ampères only. It was long felt that there was a need of some source having a candle-power intermediate between that of the carbon filament and the arc lamp.

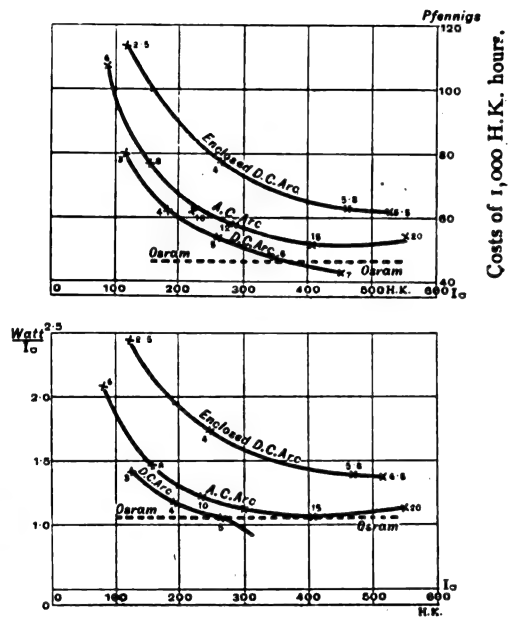
FIG. 10.

THE JANDUS REGENERATIVE ENCLOSED FLAME ARC LAMP.

The introduction of flame carbons only resulted in the production of lights of more enormous candle-power than ever, while it was found difficult to make carbon filament glow lamps of high candle-power. The Nernst lamp, it is true, did something to fill the gap, but its complexity was a disadvantage. Shortly afterwards there arose a rapid succession of small enclosed arc lamps of this kind called by various names, the Miniature, Mignon, Rignon, Baby, Lilliput, &c.

The Regina Arc Lamp.—The Regina Arc Lamp Company claim to have achieved an improvement in their Regina, Helia, and Reginula enclosed lamps by securing a more complete exclusion of the air than had been previously found possible, coupled with a reduction in the diameter of the carbons used. It is claimed, for instance, that the Regina lamp consumes only 0·8 watts per M.H.S.C.P., and will last for 250 hours without re-carboning.

FIG. 11.



COMPARISON OF ENCLOSED ARC LAMPS AND HIGH CANDLE-POWER OSRAM LAMPS. (H. Remané, Verband Deutscher Elektrotechniker, 1908.)

The numbers attached to the points on the curve represent the current in Ampères taken by the various Arc Lamps.

A consumption of only 0·3 watts per M.H.S.C.P. therefore can be obtained if one is content with a burning period of only 15 to 20 hours. An example of the extremely simple character of the mechanism of these lamps is kindly exhibited by Messrs. Marples, Leach and Co., to-night.

Comparison of Small Arc Lamps and High Candle-power Tungsten Lamps.—More recently still, however, a change in the situation has been brought about by the introduction of high candle-power Tungsten lamps, which rival the most efficient enclosed arc in efficiency and are without the disadvantage of

requiring occasional attention. The relative merits of both types of lamps has been recently treated by H. Remanè (E. T. Z., Aug. 20th, 1908), some of whose results are exhibited in Fig. 11.

HOME INDUSTRIES.

The Coal Industry.—The coal strike that threatened to affect the whole of the United Kingdom has been averted. The minimum wage asked for by the Scottish miners has been conceded, whilst the variation and limit of wages above that minimum are to be arbitrated upon. The agreement is for three years. At one time last week the country was very near what would have been nothing short of a great national calamity, for with the coal pits idle every leading industry in the country would be affected. The dispute now so happily settled will give strength to the suggestion of a Wages Board for the whole of Great Britain, having for its object the ending of those great fluctuations which occur in the coal trade where the price is up to 15s. or 16s. a ton one year, and down to 6s. or 7s. a ton another year. It would be of enormous advantage to the trade of the country if manufacturers and others were able to enter into their contracts knowing that the price of coal will not be materially interfered with. Whilst there is general satisfaction at the settlement of the dispute the crisis has lent colour to the contention of those who say that agreements between masters and men for the purpose of regulating wages work well enough whilst trade is good, but fail when the men are asked to accept lower wages. The Scotch coalowners only asked of the men what the agreement under which masters and men worked entitled them to ask, just as they previously conceded the increase of wages to which the men were entitled under the agreement. And as has been said more than once in these Notes the Eight Hours Act, which was intended to benefit the men, has, in fact, gone near to doing them serious injury, because those who supported it in Parliament, at any rate its responsible authors, did not realise the difficulties of putting it into operation without endangering the relations of employers with employed. It was only business men intimately acquainted with the trade who foresaw the complications that have followed its being put into force. In these days one does not often see quotations from Sir Archibald Alison, but a passage in his autobiography may be quoted in this connection. Having discussed the arrestment of wages in Scotland, to which throughout his strenuous life Sir Archibald was stoutly opposed, he goes on to say, "This leads me to remark how great an evil all persons practically engaged in the administration of affairs find it to be, that laws are in general passed in the legislature by persons almost entirely unacquainted with their practical operation when put in force . . . The speculative part of the assembly, whose feelings prompt them to support measures calculated for the general good, are very often destitute of the practical knowledge necessary to carry their views into effect, and vehemently support measures seemingly beneficial, but which in reality have often in the end a pernicious effect. The most obvious way of rectifying this great evil, which materially neutralises the good effect of free institutions, is to compose the Cabinet for the most part of persons trained in the administration of affairs, like the intendants of provinces in the old French monarchy—a system which produced a Sully, a Colbert, a Torcy, and a Luvois. But how such a system is to be reconciled with the necessities of government in a constitutional monarchy, depending on the majority of a popularly elected assembly, to be swayed mainly by the oratorical talents of its members, constitutes a difficulty which probably will never be wholly overcome."

Textile Workers and Half-Time.—The chief subject dealt with in the annual report of the United Textile Factory Workers' Association was the employment of children in cotton mills, and it is not surprising that regret should be expressed at the result of the ballot on the half-timer's question which gave a large majority in favour of maintaining the present system. It cannot come as a surprise to those who have studied the question that the system has a deep and strong hold on textile workers. The report says that the reason of the opposition to raising the age at which young people may begin to work in cotton mills is difficult to explain, but is it? "It is a sad fact," writes Mr. Allan Clarke in his book, "The Effects of the Factory System," "that the majority of parents in Lancashire regard children only as commercial speculations, to be turned into wage-earning machines as soon as the child's age and the law will permit. For this they oppose the raising of the age of half-timers; for this resent all legislative interference, either educational or hygienic, in the matter of their children." Two years ago the Half-time Council found that there was a progressive gain of height and weight in the all-day school children of both sexes over the half-timers of similar ages. Similar observations were made lately upon 1,000 children in each of these classes, with the following average results:—

	All-day School Children. Height. ft. ins.	All-day School Children. Weight. st. lbs.	Half-timers. Height. ft. ins.	Half-timers. Weight. st. lbs.
12½ years	4 7½	5 4½	4 7	5 3
13¾ "	4 7½	5 6	4 7	5 4
13–14 "	4 9½	5 11½	4 8½	5 8¾

This shows the half-timer at 14 to be much less in height and 2¾ lbs. less in weight than the all-day school child of the same age. Nor is it only that the half-time deteriorates physically. The effect of factory life upon the morals of both boys and girls is deplorable, whilst educationally the half-time system

stands self-condemned. The Conference adopted a resolution which appeals to all parents to make some sacrifice in the interests of the physical and educational attainments of the children, and to support the movement for increasing the age of work to thirteen years.

Cotton Ginning and Baling.—Two bales of American cotton that have been on view in the Manchester Royal Exchange show a considerable improvement on the old. These bales were ginned and compressed by the Modern Gin and Compress Company. It is claimed for this style of ginning that it raises all low cotton at least one grade. In the old system of ginning a brush is used for taking the lint off the saws, under the new system an air blast is used, and in the place where the brush usually is (directly behind the saws) there is a cylindrical chamber into which the dust and rubbish found in low cotton are driven by centrifugal force. In brush gins some of this dirt is carried into the cotton by the brush, and so on into the bale.

Artificial Nitrates. — An American has just patented in this country an invention for the manufacture of artificial nitrates. It is claimed that nitrate of lime can be produced at a cost of about £4 14s. a ton, the market price of Chili saltpetre being about £9 15s. a ton. Until now the principal attempts that have been made to fix atmospheric nitrogen may be classed as (1) processes in which atmospheric nitrogen is burnt to nitrous or nitric acid; and (2) processes in which atmospheric nitrogen is combined by means of carbides, obtained by fusing together in an electric furnace metals or metallic oxides and carbon. The cost of the nitrogen so obtained has been comparatively high, except where power can be obtained from waterfalls at a very low cost. The patent referred to above describes a process and apparatus by means of which sulphur may be burned on a commercial scale so as to remove all the oxygen from the stream of air supplied for its combustion. By this means, it is claimed, nitrogen of great purity can be obtained, and the inventor says that in practice he has rejected all nitrogen-gas which did not reach a purity of 99·6 to 99·8 per cent. Also by placing iron filings in the receiver for a few days the ·2 of oxygen may be removed, leaving absolutely pure nitrogen. Cyanide of potassium can, it is claimed, also be produced at a cost of about 8½ cents a pound, the market price being about 22 cents per lb.

The Hop Industry.—The disastrous result of last year's operations led to a large reduction of the area in hop cultivation this year, and the very unfavourable weather of the present summer makes it very unlikely that there will be anything like an average yield in 1909. Some gardens have been abandoned already on account of the aphis blight, and many are in a precarious condition because the damp weather prevents the killing of the aphis. Systematic washing prevents the ravages of blight, but constant washing is a costly business, and many growers, disheartened by the experience of last year, have decided to let the crop take its chance. Even where the aphis has been held in check the yield will be small, but having regard to the restricted area under hop cultivation this year in America, as well as this country, prices are likely to be good. It is to be feared, however, that there will be nothing in the circumstances of the present year to arrest the decline in hop cultivation which has been going on for the last twenty years, and which, in another twenty, is likely to leave the country without any hop fields, even in Kent.

QUESTIONS AND ANSWERS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

ANSWERS.

COPRA.—There is, according to the results of some experiments of mine some time ago, no great difficulty in preventing the formation of the "mould" (*Penicillium*) referred to by "Malay," in the *Journal* of 30th ult. In cases where the odour (which, though fragrant, is somewhat persistent) is not an objection, impregnation of the copra, and especially of the sacks, casks, or cases containing it, with oil of thyme *(Ol. Thymus vulgaris)* is the most effectual method. The oil should be applied in a fine spray, about half a fluid ounce per cwt. of copra being sufficient for this purpose. As an *odourless* application, a warm saturated solution of boric acid answers well. The copra should be well washed, soaked, or sprayed with this, and sun-dried, before it is packed. A little finely-powdered boric acid should also be dusted over the top layers of the copra.—W. LASCELLES-SCOTT.

Chemical and Physical Laboratories,
Little Ilford, Essex.

BLEACHING STRAW FOR HATS.—Assuming that "Chittagong" desires to treat the fibre of the Tamil or "Talipot" palm-leaf (*Borassus flabelliformis*), or "plaits" derived therefrom—for there are several others to which the term "Palmyra Palm," is improperly applied—I think I can furnish him with the desired information. But the details vary in certain

respects with the condition of the material, hence it might be as well if he would favour me with a few specimens of the actual plaits to be treated. I may remark that, some years back, I had occasion to conduct some researches upon this very question for the late Dr. J. Forbes Watson, Director of the India Museum, to which I was then Consulting Analyst. Speaking in general terms, it may be said that no form of "sulphur-bleaching" proves so satisfactory with any "Palmyra" plaits, as with the common "straws." There are two classes of process giving good results with "Palmyra," which may be respectively designated as the "ozonic" and the "nascent oxygen" methods, the latter being an essentially chemical one. I am acquainted with the "secret" details of both, and shall be happy to send a further reply on receipt of "Chittagong's" specimens.—W. Lascelles-Scott.

Chemical and Physical Laboratories,
Little Ilford, Essex.

NOTES ON BOOKS.

Notes from a Painter's Life. By C. E. Hallé. London: Murray, 1909. 6s. net.

The chief interest in Mr. Hallé's sketch is certainly in the account he gives of the founding and carrying on of the Grosvenor Gallery and the New Gallery. This is a record of permanent value. Besides, there are many pleasant notes on people he has known and things he has seen. By his own account his relations with his numerous friends and acquaintances were always pleasant. At all events, the unpleasant side is left unrecorded, "*Horas non numerat nisi serenas*."

A History of Art. By Dr. G. Carotti. Vol. II. (Part I.) Early Christian and Neo-Oriental Art. European Art North of the Alps. Translated by Beryl de Zoete. London: Duckworth and Co. 5s. net.

The first volume of this work, which dealt with ancient art from the Memphite age to the later Roman age, was noticed in these columns in December last. In the present volume some sixty pages are devoted to early Christian art, and the remaining two hundred and sixty to neo-Oriental and European art. From the scope of the book it will be seen that Dr. Carotti makes no claim to describe with any minuteness his subject—indeed, he freely admits that his work is elementary and introductory in its intention; but, as the translator observes, "the value of such a panorama depends perhaps less on its fulness than on the stimulus it affords the adventurous imagination to more extensive researches." Dr. Carotti is eminently qualified to sketch in large outline the history of art; while for those who desire to pursue the subject, or any portion of it, in greater detail—and to stimulate such a study is, no doubt, the author's principal object—the bibliography at the close of the volume should prove invaluable. Three hundred and sixty illustrations add much to the usefulness of the book: the only pity is that they could not have been reproduced on a somewhat larger scale.

GENERAL NOTES.

The Architectural and Topographical Society. — The Architectural and Topographical Society, which was founded about a year ago, is appealing for a minimum sum of £500, "to ensure the effective continuation of its work until such time as the annual subscription list shall be equal to the necessary disbursements." The society's object is to make complete historical records of the ancient buildings of these islands from the introduction of civilisation to the year 1800, and already in the short period that has elapsed since its establishment, the society has published complete accounts of the buildings in seventeen parishes. The recent appointment of Royal Commissions to make an inventory of the ancient monuments of England, Scotland, and Wales shows that the State appreciates the need for such work, while further testimony to its value is furnished by the fact that many of the leading institutions interested in the subject are subscribing to the Architectural and Topographical Society. The appeal is signed by the Earl of Plymouth, Lord Avebury, Sir Aston Webb, Mr. Thomas G. Jackson, and other well-known authorities, and it is to be hoped that the society will be successful in raising the modest sum necessary to carry on a work of such great national interest and importance. Subscriptions should be sent to the Secretary, 33, Old Queen-street, Westminster, S.W.

British Machinery in Japan.—It is satisfactory to find that the British share of machinery sent to Japan in 1908 increased from 52 per cent. in 1907, to 59 per cent. This large proportion was mainly due to increased purchases of cotton-spinning machinery, but except in the cases of electric and paper-making machinery, and to a lesser extent as regards pumping and sawing machinery, the United Kingdom holds a long lead over her two nearest competitors, the United States and Germany. In electric machinery Great Britain has dropped behind, and in his report on the trade of Japan, just issued, Mr. E. F. Crowe, Commercial Attaché to his Britannic Majesty's Embassy at Tokio, says that the outlook is not very promising, as one of the largest American concerns is about to combine with an already established Japanese engineering works, and start manufacturing locally on a big scale. The number of spinning companies in Japan, at the end of 1908, was thirty-five, with 1,358,000 working spindles, of which 1,310,000 were ring and the balance mule. Several of the leading spinning companies have now taken to manufacturing.

Journal of the Royal Society of Arts.

No. 2,960. VOL. LVII.

FRIDAY, AUGUST 13, 1909.

All communications for the Society should be addressed to the Secretary, John street, Adelphi, W.C.

NOTICES.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

The Council of the Royal Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the committee of that fund in 1876, on condition that the interest thereof be spent in prizes to "Students of Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damasks, Chintzes, &c., regulated by the principles laid down by Owen Jones."

Competitions, under the terms of this Trust, have been held annually since 1878.

The next award will be made in 1910, when six prizes are offered for competition, each prize to consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's bronze medal.

The prizes will be awarded on the report of the examiners in the national competition of the Board of Education. The designs must be submitted in the usual manner to the Board of Education, South Kensington, S.W., by the 1st of April, 1910. They must be marked "In competition for the Owen Jones Prizes," and must comply with the regulations of the Board of Education.

No candidate who has gained one of the above prizes can again take part in the competition.

Notice of the offer of these prizes has been sent to the Schools of Art connected with the Board of Education; and copies of the circular can be obtained on application to the Secretary of the Royal Society of Arts, John-street, Adelphi, London, W.C.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

MODERN METHODS OF ARTIFICIAL ILLUMINATION.

By Leon Gaster, A.M.I.E.E.

(Editor of the *Illuminating Engineer.*)

PART II.*

VAPOUR LAMPS.

Introduction.—It will be remembered that at the beginning of Part I. I referred to the existence of two distinct methods of generating light—by incandescent solids and by luminous gases; I have also mentioned how we may expect to secure more efficient results by the utilisation of radiation of the latter variety.

A flame lamp, as we have seen, utilises both types of radiation, and accordingly exhibits one disadvantage of luminescence, namely, the fact that we usually succeed in producing one portion of the spectrum with greater intensity than another, and therefore get light of a colour which differs considerably from daylight, and might even be practically bizarre.

The Mercury Arc Lamp.—I have now, however, to speak of another type of lamp, which seems to utilise luminescence alone, namely, that employing metallic vapours. It may be said at once that the only metal which has been successfully employed in this way, is mercury.

As in the case of incandescent lamps it may again be mentioned that not a little of the early pioneer work in this department was done in England, some of the earliest efforts being ascribed to Rapieff in Russia, and to Way and, more recently, to Bastian in Great Britain. The lamp was brought to a more practical stage by the subsequent experi-

* The Course consisted of four lectures, delivered on February 15th and 22nd, and March 1st and 8th. In re-arranging the material for publication in the *Journal*, the lecturer has preferred to divide it into six parts.

ments of Arons in Germany, and Cooper-Hewitt in the United States. Both of these investigators utilised a long tube containing mercury vapour, which is essentially the same as that used in the mercury vapour lamps of to-day.

There have, however, been a number of very ingenious inventions regarding the regulating mechanism of these lamps, into which I cannot enter in detail. A few of the most recent types of lamps of this kind are shown here by the kindness of the Westinghouse Company to-night.

The chief point of interest in the most recent type introduced by this firm is the introduction of a new automatic system of starting the lamp without "tipping," the arc being started by the impression of instantaneous high P.D. across its terminals.

The efficiency of these lamps is difficult to determine, because of the peculiar character of the light, and also because the extended nature of the source makes accurate photometry very difficult. It has, however, been stated that a consumption as low as 0·6 watts per candle-power has been obtained, and this was long thought to be the limit, since both an increase and a decrease in the pressure of the mercury vapour in the tube proved to lead to a fall in the efficiency.

The great length of tube (those of 110 volt lamps are nearly 1 metre in length and 3 to 4 centimetres in diameter), though promoting diffusion of light, is a disadvantage in some respects.

The greatest disadvantage under which these lamps labour, however, is the peculiar colour of the light. A line spectrum pure and simple is obtained, the greater bulk of the radiation being concentrated in three lines into yellow, green, and blue respectively, and the red element being almost entirely absent. This line spectrum is, of course, characteristic of luminescence.

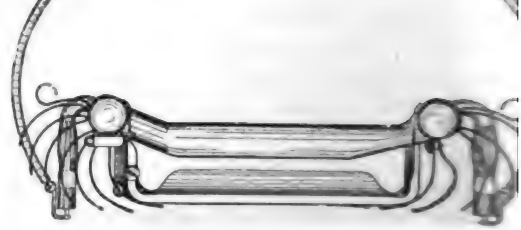
I cannot dwell upon all the attempts that have been made to improve the colour of the light. They are many. For instance, it has been proposed to mix lithium salts in the mercury in order to provide red lines in the spectrum; also to modify the spectrum by the use of special electrodes; also to derive red light by the degradation of the ultra-violet rays given by the lamp by means of fluorescence. None of these methods appears yet to have crystallised into anything very practical.

The Küch Quartz-Tube Lamp.—Recently, however, an interesting advance has been made in Germany by Dr. Küch. (Paper read before the Verband Deutscher Elektrotechniker 1907.) Hitherto, if the pressure within the lamp was increased beyond a certain point, the increase in temperature caused glass of an ordinary variety to melt, and therefore brought the lamp to a premature end.

Quartz-Tube lamps, intended mainly for the production of ultra-violet light, and not for ordinary purposes of illumination, had previously been introduced by Heraeus, in Hanover, Germany.

FIG. 12.

General Appearance of Küch Lamp.



Small Quartz Tube.

THE KÜCH LAMP. A Mercury Vapour Lamp utilising a small tube composed of special quartz glass.

Dr. Küch, however, constructed a tube of very refractory special quartz glass which would stand a much higher temperature than ordinary glass; it was then found that the efficiency increased as the power given to the lamp was increased, in accordance with the curve shown in Fig. 13.

It will be seen that the consumption per candle-power, after rising to a maximum, begins to fall again, until eventually a value of about 0·27 watts per M.S.C.P. is attained.

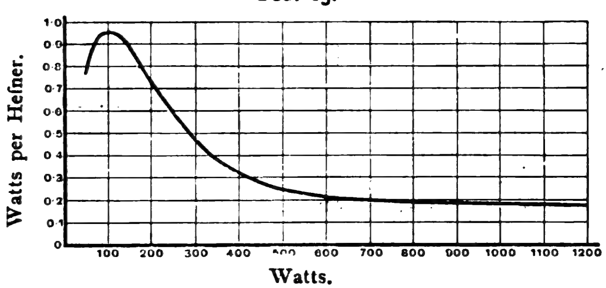
The quartz 110 volt tube is only about 8 centimetres long and 1½ centimetres in diameter. I may say that the glass of this tube represents a very considerable item in the total cost of the lamp.

many for purely photographic purposes, some of them, such as the Heraeus lamp, employing quartz glass; others, like the Uviol lamp, utilise an envelope composed of a newly-discovered glass, which transmits ultra-violet energy.

The Moore Tube. — And now I have to mention a very interesting type of an illuminant recently brought out in the United States by Mr. D. Macfarlane Moore (Am. Inst. of Elec. Engineers, 1906).

It has, of course, long been known that gases can be made luminous when subjected to an electrical discharge in a highly rarified condition. The ordinary Geissler and vacuum tubes are illustrations of this principle. To

FIG. 13.



CURVE ILLUSTRATING EFFECT ON EFFICIENCY OF KÜCH LAMP OF INCREASING WATTAGE AND TEMPERATURE.

Another interesting characteristic of the lamp is the fact that at the high temperature and pressure existing within the lamp luminescence is partially replaced by ordinary incandescence, and the line spectrum broadens out into a more or less continuous one, with the result that the colour of the light is distinctly improved, and contains a certain amount of red rays.

Another striking peculiarity of the lamp arises from the fact that quartz glass allows ultra-violet light to pass through, whereas glass of the ordinary variety is gradually decomposed by it, or degraded by it into heat-energy. As a result the quartz-tube lamp has a very powerful action on the skin and eyes, and is also believed to possess special uses for the destruction of bacteria, the sterilisation of water, &c. For ordinary purposes of illumination it is necessary to screen the quartz tube with an absorbing glass envelope, which transmits the visible radiation, but largely absorbs the ultra-violet light.

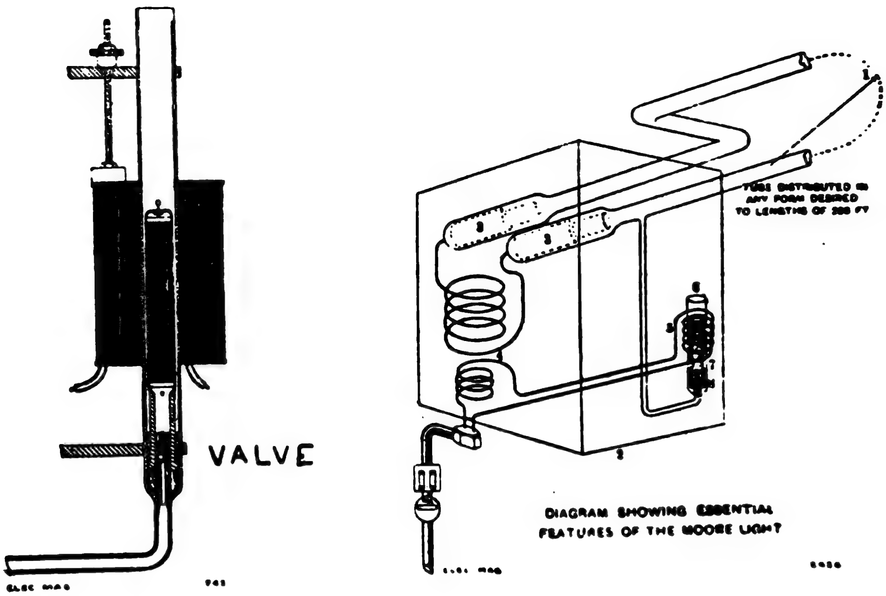
It has been mentioned that lamps of a similar character have been devised in Ger-

Tesla and others had occurred the idea of utilising this effect in order to secure an efficient illuminant. It was, however, found that the condition of the gases within the tube quickly changed, partly owing to the absorption of gas by the electrodes, and means had, therefore, to be adopted to control automatically the conditions of the gaseous contents of the tube. These devices, however, were for long unreliable.

To Mr. Moore belongs the credit of having very carefully studied the conditions and qualities of gases most favourable to the production of light, and the invention of an extremely ingenious form of valve by the aid of which the pressure of the gas within the tube was maintained exactly constant. The essential details of this valve and the lamp in general are shown in Fig. 14. During my recent visit to the United States I had the privilege of seeing these lamps in action.

The illuminant consists of a long tube, which may be 30 ft. or 40 ft. in length, filled with suitable gases at a very low pressure and subjected to an electrical high tension discharge

FIG. 14.



DETAILS OF MOORE TUBE.

FIG. 15.

MOORE TUBE INSTALLATION LATELY IN USE IN THE COURTYARD OF THE SAVOY HOTEL, LONDON.

from a small electrical transformer. If a house is lighted by this system the tube is supposed to ramify round the rooms up the staircase, &c., and, in fact, entirely to replace the ordinary wiring.

The consumption per candle-power of the tube varies according to the nature of the gas used; so does the colour of the light. Thus a tube filled with nitrogen yields light of a yellowish, pinkish colour. But by using carbon-dioxide Mr. Moore claims to obtain a beautifully white light which resembles daylight more closely than any other known illuminant.

Fig. 15 represents the Moore tube installation recently in use in the courtyard of the Savoy Hotel, and is, I believe, the only installation put up in this country. This was described by Dr. Fleming in an early part of the *Illuminating Engineer* (Vol. I., Jan., 1908, p. 19), and he states that a consumption of 1·78 watts per candle-power was obtained. The advocates of the system, however, contend that this does not truly represent the value of the light because its diffuseness and low intrinsic brilliancy enable one to secure better results, as far as the eye is concerned, than photometrical experiments would suggest.

The Relative Costs of Different Illuminants.—Having described so many electrical illuminants I may, perhaps, be expected to give some idea of their relative costs as compared with gas lighting, &c. I may explain that I myself only regard Tables of this kind as of very general interest, because the actual decision in any practical case depends very largely upon the local conditions. This is brought out by a Table containing some results of Monsieur Blondel in a paper to which I have previously referred.

You will also see that the relative costs of gas and of electricity can vary very greatly, even when lamps of the same type are considered.

Cost of Gas and Electric Lamps.

(Assuming Gas Costs 0·2 Fr. per cubic metre, Electricity 0·7 Fr. per KW. hours.)

	Incandescent Gas.		Incandescent electric lamps. Carbon. 32 C.P. for 300 hours.		Incandescent electric lamps. Tungsten. 32 C.P. for 1000 hours.

P, price of *bulb* in the case of incandescent lamps; *renewal of glower and ballast* in the case of Nernst lamps; renewal of *electrodes* and *trimming* for arc lamps; *tube* for vapour lamps.

OTHER METHODS OF GENERATING LIGHT—PHOSPHORESCENCE AND FLUORESCENCE.

There remains one conceivable method of generating lighting which many of you may consider fanciful, but which, nevertheless, seems to me to possess great scientific possibilities, and, indeed, has been carried to wonderful perfection for certain purposes by Mr. Hammer in the United States and others. I allude to the phenomena of phosphorescence and fluorescence.

ultra-violet into visible light energy which takes place only while the stimulus is applied.

Phosphorescence, on the other hand, is usually taken to indicate an effect of this kind which continues after the stimulus is removed, so that we may excite a phosphorescent substance, and subsequently use the light that continues to be emitted.

Mr. A. C. Cossor has kindly arranged for the exhibition of a few experiments illustrating these phenomena. Here, for instance, are

some specimens of Willemite, which fluoresce under the rays of the Uviol tube. A still more interesting example of induced fluorescence is the effect of only 5 milligrams of radium in exciting quite a large piece of this substance. Now that the lights are turned down you will observe a distinct green luminous appearance of the Willemite, which appears as the radium is brought near, and disappears again as it is withdrawn.

It has been proposed to modify the spectrum of the quartz mercury lamp by painting the tube with fluorescent substances.

Professor S. P. Langley, who studied the nature of the phosphorescent light from a firefly, characterised it as the most efficient illuminant in existence, and the researches of Nichols and others suggest that for some reason or other phosphorescent materials almost invariably contain the greater part of their radiation within the visible spectrum. It may be that these researches will lead to new methods of illumination in the future.

GAS.

INTRODUCTION.

In dealing with the programme of my lecture on gas, I find myself again confronted with a subject which is extremely vast, and to many aspects of which separate and exhaustive Cantor lectures have been devoted by my predecessors.

For instance, Professor Vivian Lewes alone has dwelt on the practical aspects of gas lighting, the theory of the incandescent mantle, and other allied subjects, at great length, and I should like to refer those of you who wish to receive fuller details on these points, to the original lectures.

I may, however, make clear at the very beginning of this lecture, that I propose to restrict myself entirely to gas lighting proper, and not to deal with generating problems and distribution, except in so far as they are immediately connected with illumination. I shall not, therefore, trouble you with an exhaustive description of the processes by which gas is produced, nor with particulars of the composition of ordinary town gas, water gas, producer gas, or any of the other varieties of gas that have played a more or less direct part in gas lighting.

HISTORICAL.

It may, however, be interesting to give a few particulars of the early development of gas lighting in Great Britain and other countries, and in this connection I should like to refer you to an interesting article by Dr. R. Böhm (*Illuminating Engineer*, February, 1908), and also to some remarks on this subject in Mr. W. H. Y. Webber's book on "Town" gas.

One of the very earliest records of the manufacture and storage of illuminating gas, is that in the Transactions of the Royal Society for 1739, when the experiments of the Rev. Dr. John Clayton on this subject were communicated.

Dr. Dundonald, it is also known, carried out some experiments on the subject in 1787, but William Murdoch, who took up the subject a few years later, and who lighted his factory in Redruth in 1792, and his factory at Soho, Birmingham, in 1802, is regarded as in many respects the father of the industry. Subsequently the Chartered Company was formed in London in 1810, by Winzler, a Moravian, who had become interested in the subject, and travelled to London to give his ideas practical shape, and in 1813, Westminster Bridge was lighted by gas for the first time.

A name which, like that of Murdoch, will always be inseparably connected with the early beginning of the gas industry in this country, is that of Mr. Samuel Clegg, a pupil of his, who afterwards carried out his work, in connection with the Chartered Company, with indomitable perseverance and ingenuity.

England can, therefore, claim to have done much of the early pioneering work in gas lighting, though similar work had been done in Paris, by Lebon, in 1784, and in Germany even earlier; it was not, however, until the 19th September, 1827, that the famous street of Unter den Linden, in Berlin, was lighted by gas.

It has often been said that nothing was so stimulating to the development of gas as the rise of electricity. On the other hand, electrical engineers (who have certainly had sufficiently great initial difficulties of their own to overcome) ought to remember with gratitude the work of the gas companies in overcoming early prejudices, and paving the way for their future efforts. At the time when the Chartered Gas Company was formed, the idea of an illuminant transmitted to a distance was one that the general public found it impossible to conceive, and Clegg, in his early efforts, was hampered by an incredible degree of misunderstanding as to what lighting by gas really consisted of. In addition, he had to face the difficulties of securing materials, and to devise means of overcoming unexpected obstacles.

For instance, Clegg is said to have been at one time unable to obtain the necessary metal piping, and to have had recourse to strings of old musket barrels screwed together.

For a time, there was no means of measuring the gas supplied; consumers hired their lights at a yearly rental, and there was much misunderstanding and dissatisfaction. The early difficulties of gas in London were accentuated by the existence of several competing companies, who apparently were not above exceedingly unscrupulous tactics in competing with one another. Mr. Webber, for instance, relates how one company would occasionally instal a show lamp, free of charge, in order to attract a consumer, and were not above attaching it to the mains of a rival.

Actions like these led to a species of guerilla warfare between the competing companies. Gangs of navvies were employed for offensive and protective purposes, and the streets were in an almost continuous state of upheaval owing to their exertions. Eventually, however, an amalgamation of these various companies was effected, and the supply of gas began to resemble more closely the conditions of the present day.

Early Type of Burners.

The earliest method of burning gas was, of course, by the use of the so-called flat flame burners, which we should now consider extremely inefficient, for they yielded only about two to three candle-power per cubic foot of gas, even under the most favourable conditions. Of course, however, it must be remembered that gas, unlike electricity, may vary in quality in each district. For instance, the Act of 1860 prescribed that the town gas burned under certain specified conditions in a standard Argand burner should give 15 candle-power; but the rich local cannel coal in Scotland was capable of yielding as much as 20 or even more candle-power.

Similar results could, of course, be obtained by enriching the gas by the addition of some volatile hydrocarbon. For instance, in the "albo-carbon" burner, the gas must pass over naphthalene, which presently became volatile in the heat of the flame, and mixing with the gas emerging from the burner considerably improved its quality. It was, however, but a cumbrous device.

Somewhat better results than those mentioned above could also be obtained from the Argand burner, but this again occasioned a more delicate and unsteady flame. Yet another early improvement was in the direction of the so-called regenerative lamps, in which the gas was heated by the flame before it passed into the burner, and a greater flame temperature and improved candle-power were obtained as a consequence. The Wenham lamp depended on this principle.

Table of Efficiencies of Various Burners.
(W. Grafton, Practical Gasfitting.)

Type of Burner.	Specific Consumption. (Candle power per cubic foot of gas per hour.)
Flat-flame, Batswing..	4–6·1 (with 30 candle gas)
Ordinary Argand	2 : 7–2·9 (with 16 candle gas)
Standard Argand	3 : 2–3·35 (with 16 candle gas)
Albo-Carbon light	5–6
Regenerative lamps ..	10–12
Acetylene	generally 35, best conditions 48.

High-pressure incandescent	40–50
Keith high-pressure Light	60–70

The Coming of the Incandescent Mantle.

It was, however, not until the introduction of the incandescent mantle and the Bunsen burner that any really great progress seemed possible.

I need not enter in any detail into the wonderful researches of Auer Von Welsbach. The lectures of Prof. Vivian Lewes before this Society have given us an insight into the theory of the mantle, as far as it was known at the time of these lectures.

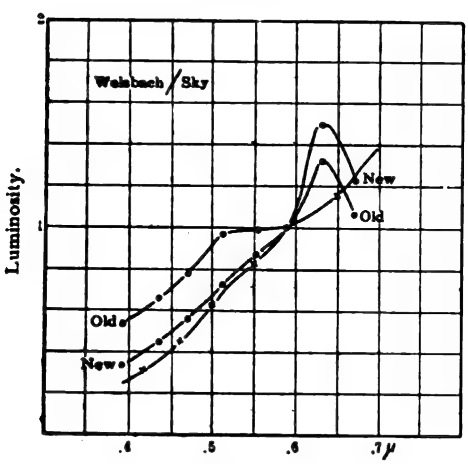
Another instructive paper dealing with the theory of the radiation of the mantle in some detail, was that of Professor Rubens, before the British Association, a few years ago.

It has been suggested that the effect is due to pure thermal incandescence, and that the temperature of the mantle is far hotter than that of the Bunsen flame. Again, it has been supposed that catalytic action takes place among the oxides which are present in the mantle. It is also known that the rare earths are peculiarly capable of showing luminescence, and that only when small impurities are present does this luminescence take place, and lastly, it has been pointed out that the Bunsen

flame is rich in the ultra-violet rays that are supposed to call this luminescence into play. Yet it does not appear that we have arrived at a complete understanding regarding the action of the mantle at the present day.

Colour of Light from Mantles.—Even after this discovery, however, the mantle was far from perfect. Its luminosity deteriorated very quickly, and the quality of the light was of an unpleasant greenish colour. To-day these drawbacks have been very largely removed. The following figure for instance,

FIG. 17.



SHOWING SELECTIVE RADIATION AND PECULIAR COLOUR OF OLD TYPES AND MANTLES.

(Nichols, Trans. Illum. Eng. Soc. New York, May, 1908.)

shows the results of Nichols, for mantles of the present day compared with old-fashioned ones as regards the colour of the light produced. It will be seen that the more old-fashioned mantles yielded a spectrum showing considerable selective radiation, and a corresponding deviation from daylight, which is much improved in the later varieties.

Durability of Mantles.—Other incidental difficulties have been the tendency of mantles to burn into such a shape as not to be completely encircled by the flame.

In this connection, it is somewhat interesting to observe a recent device consisting of an infusible conical core, which is placed over the crutch of an incandescent mantle, and is said to guide the flame on to the mantle itself, and to result in an improvement of 20 per cent. in efficiency. [Since writing the above, I observe that Mr. C. Forshaw, in a paper read at the annual meeting of the Gas Institute this year, describes some experiences of cores of this kind, which are also satisfactory.]

After referring to the other qualities of mantles of importance, perhaps I may be expected to give some details of life tests. I may, therefore, refer to some tests undertaken about two years ago by Böhm (*Das Gasgluhlicht*, 1905), according to which you will see that relatively efficient results could apparently even then be obtained for 300 to 600 hours of life. (Fig. 18, p. 784.)

As in the case of electric glow lamps, however, one feels that practical conditions are widely different from those prevailing in laboratory tests. Makers of lamps in England, at the present day, feel that one of their chief needs is a really good mantle, those in even ordinary burners requiring renewal on the average every 200 hours. There are so many respects in which a laboratory test is exceptionally favourable to the performances of mantles. For instance, reference need hardly be made to the effect of even a slight vibration; this, it is true, has been reduced by the many ingenious anti-vibration devices which Mr. George Helps, of Nuneaton, Messrs. Parkinson and Cowan, and others, have devised. In addition, as Mr. Wild has recently shown (*Journal of Gas Lighting*, April 2nd, 1907; *Illuminating Engineer*, 1908, p. 783) the results from any mantle depend very greatly on such factors as the pressure and quality of gas available, the type of chimney used, and the adjustment of the proportions of gas and air. The variations in these conditions really make it essential for a gasfitter to adjust each burner to suit the local requirements. (Fig. 19, p. 785.)

In addition, I need hardly say that the occasional blowing out of accumulated dust in the burner, is necessary. In public lighting, too, even the best lamps are not always unaffected by gales of wind, which have a very important influence on the question of renewal. Altogether it is highly probable that the termination of life of a mantle is usually determined by breakage, rather than diminution of candle-power, just as is not infrequently found to be the case for metallic filament lamps. Probably too, as in this case, variations in pressure are not without influence. It has even been suggested that a governor ought to be installed at the meter of each and every consumer.

New Types of Mantles.—Besides the other improvements referred to in mantles, notable advances in their durability have lately been achieved. The introduction of the Ramie

mantle about 1898 was regarded as a great advance.

Two years ago a new departure in incandescent lighting was introduced by the Plaissetty Company in the form of the Monarch soft or non-incinerated mantle. The advantages of a soft mantle for convenience in packing and immunity in handling and transit are obvious. The greatest danger to inverted incinerated mantles, namely, the risk of fracture at the ring in packing, is claimed to be avoided. But the greatest advantage offered by the soft mantle, it is said, is the latitude which it gives in burner development. By the use of a non-incinerated fabric, shapes and sizes can be obtained, which are practically impossible in an incinerated form.

For a soft mantle certain conditions must be satisfied :—

1. The illuminating salts should be compact and in oxide form.

2. The fabric should contain the minimum of cellulose.

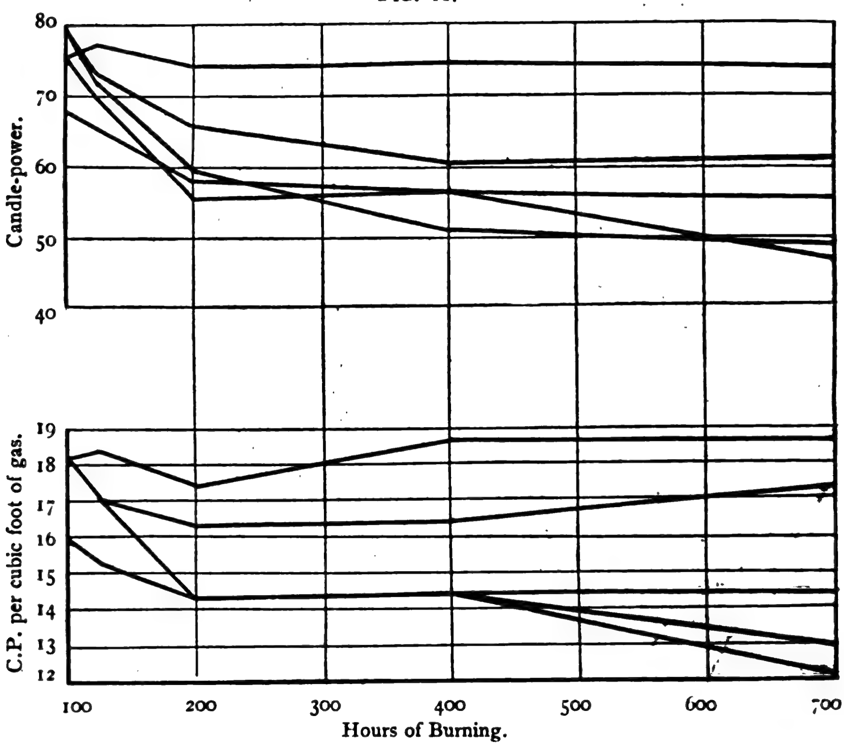
3. The fabric should be shaped and the cellulose easily burnt out.

Another type of artificial silk mantle recently brought out, that of the Cerofirm Company, is stated by Böhm (*Illum. Eng.*, June, 1909), to be a great advance, having like the Plaissetty mantles, good elastic properties, together with improved efficiency and a whiter quality of light than was obtained previously. This is said to be due largely to the special nature of the impregnating salts used, which, after burning off, leave a very fine and durable surface of oxide behind.

Next I may mention an interesting new development, namely, the Hella Bushlight, which, as you will see by the example kindly supplied here to-day, consists not of a mantle but of a bundle of rods composed of suitable rare earths. (See Patents Nos. 3785 and 9622 of 1908.)

The great claim made for this system is, that, while yielding an efficiency approaching that of ordinary mantles, the illuminating apparatus itself is exceptionally durable.

FIG. 18.



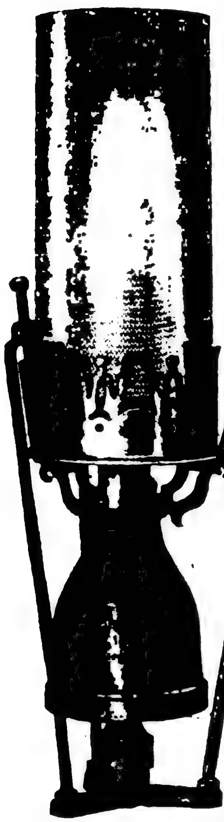
LIFE-CURVES OF INCANDESCENT MANTLES (Böhm).

DEVELOPMENT OF THE BUNSEN BURNER.

I may now make some reference to the development of the Bunsen burner, the other important factor in the incandescent light.

The efficiency yielded by an incandescent mantle depends to a very large extent on the flame temperature obtainable, and the possibility of securing perfect combustion of the gas supplied. The original Bunsen burner only consumed about one part of gas to two of air, whereas the average kind of town gas requires about 5½ to one for complete combustion. By suitably designing the burner we can make a

Fig. 19.



Type of Anti-Vibration Holder. (Messrs. Parkinson and Cowan.)

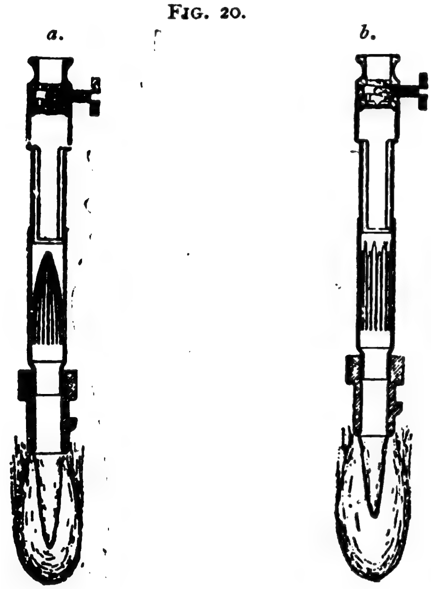
mixture of about one of gas to three of air, but any attempt to produce a poorer mixture than this causes the flame to light back, if special provision is not made to avoid it. The device introduced into the ordinary incandescent burner to avoid this possibility merely consisted of a wire gauze acting on the principle of the Davy safety lamp.

Other details in the burner have been devised for the purpose of securing an intimate mixture of gas and air. For instance, in the Welsbach-Kern burner, a tapering cylinder is added to the burner in order to give the gas and air opportunity of mixing completely, and a peculiar twisted head is fitted with the object of producing a swirling motion of the mixture as it appears at the nipple and is burned.

Inverted Burners.

Within the last few years a very great advance has been effected by the introduction of inverted burners. The early experiences of this burner were not entirely satisfactory, and there were many initial difficulties to overcome—so much so that even in 1906 there were many who doubted whether the burner would ever become a commercial success. For

Fig. 20.



a. Sketch of Inverted Bunsen Flame when first lighted, thermostatically controlled.

b. Sketch of Inverted Bunsen Flame after burning ten minutes, thermostatically controlled.

(Whitaker, Trans. Ill. Eng. Soc., New York, Dec., 1907.)

instance, the tendency to light back appeared to be accentuated, there was a tendency to produce a hissing noise, and the conduction of heat upwards to the fitting caused it to wear out very rapidly. Most of these difficulties were got over by suitable designing of the mixing-chamber, &c., though other special devices are necessary for the solution of one theoretical difficulty, namely, the fact that the burner, after burning say ten minutes, becomes so much hotter as a whole than it was originally, as to call for slight adjustment of

proportions of gas and air in order to obtain the most perfect results.

A very ingenious method of controlling the proportions of gas and air, and of getting over this difficulty has been described by Litle and Whittaker (Trans-Illuminating Eng. Soc., New York, 1907); it involves a special thermopile-controlled valve, by means of which the proportions of gas and air necessary for complete combustion are automatically regulated. (Fig. 20, p. 785.)

In passing it is interesting to note that Clegg, very early in the history of gas lighting, devised a self-closing burner with thermostatic

FIG. 21.

action for the purpose of shutting off the gas whenever the flame became accidentally extinguished in order to satisfy the fire insurance authorities (Webber, "Town Gas and its Uses," page 28).

The inverted incandescent mantle, however, is of course to-day an accepted fact, and possesses very distinct merits. For instance, apart from improved efficiency, the attachment of the mantle by means of its entire rim is distinctly preferable to the system characteristic of the upright burner of merely hanging the mantle on a crutch.

I cannot find time to refer to the many devices by which the difficulties inherent in inverted burners have been overcome. A few examples of such devices are exhibited here to-night. For instance, the Hands cooled burner is provided with deflecting wings which conduct the heat away and prevent discolouration of the fitting. The principal advantage claimed for this burner is that its winged deflections serve the purpose of preventing discolouration of fittings, and keep the head of the burner cool. In addition, the air and gas

FIG. 22.

FIG. 23.

TYPES OF BLAND INVERTED BURNERS.

adjustment is claimed to be exceptionally easy, the head always remaining perfectly cool after it has been burning for hours.

A test, I am informed, has recently been made by one of the largest gas companies in this country, according to which a burner was fitted on a polished brass adapter and was left burning from 7 a.m. until 10 p.m. for a period of six weeks. At the end of that time the

finish of the adapter was found to be not discoloured or injured in any way whatever. (Figs. 22, 23.)

In the Bland burners, again, a patent anti-lighting-back arrangement is provided, and there is also a special carrier to grip and support the mantle, which is not attached to the actual burner, with, it is claimed, the result that the life of the mantle is prolonged, because the shocks occasionally administered to the burner are not communicated to the mantle directly.

FIG. 24.

OMAR INVERTED BURNER. (Moffat.)

Other modern types of inverted burners on exhibition are the Omar and Mascot types of Messrs. Moffats, Limited. One essential detail of these burners is the use of a perforated outer metal casing with which the products of combustion are not allowed to come in contact owing to the use of an opal glass collar. In this way it is claimed the burner retains its original appearance for months without becoming visibly discoloured or tarnished.

In the Mascot burner, in addition, the air is slightly warmed before reaching the mixing chamber, some of the waste heat of the burner being utilised for this end. This serves the double purpose of producing a good velocity of the gas and air mixture and favourable conditions of combustion, and at the same time of cooling the parts of the burner over which the mixture passes and preventing consequent discolouration.

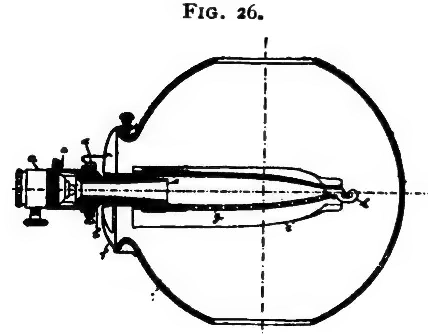
In addition, inverted mantles have a smaller and more compact form, and seem not to deteriorate and split so readily. The advan-

FIG. 25.

MASCOT INVERTED BURNER. (Moffat.)

tage on which most stress has been laid, however, lies in the improved distribution of light, the maximum candle-power being usually obtained in a downward direction. The exact nature of the distribution curve

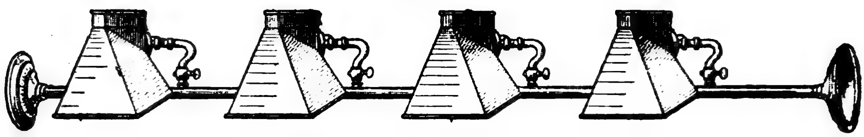
FIG. 26.



"TUBUS" HORIZONTAL BURNER.

depends to some extent on the shape of the burner. They may be longer than they are broad, and it is then possible to obtain a good downward component, and yet at the same time stronger intensity at a downward angle;

FIG. 27.



"TUBUS" BURNERS AS ARRANGED FOR SHOP LIGHTING.

this, of course, is the nature of curve we mainly desire for street lighting, and inverted mantles, as will be mentioned later, have recently been applied for this purpose, with success in Berlin, and more recently still in Fleet-street, London.

It may be new to some of you to learn that a firm in Berlin manufacture a type of burner with a mantle in a horizontal position (Czudnochowski, *Illuminating Engineer*, Vol. 1., 1908, p. 582). It is called the Tubus burner, and is claimed to be specially suitable for the illumination of shop windows, where a strong downward component is desired. (Figs. 26, 27.)

A SUNSET ON MATHERAN.

BY SIR GEORGE BIRDWOOD, M.D., K.C.I.E., LL.D.

This ethnographical vignette was originally a footnote on the name of the late Honourable Jugonnathjee Sunkersett, of Bombay, in my Introduction to Mr. Talyeikhan's "Representative Men of India" [W. and H. Allen, 1880]; and is here reproduced, with my latest emendations, as supplementary to the account given by me in the issues of our *Journal* of October 11th, and November 29th, 1907, of the "Burst of the Monsoon" in Western India.

The idolatry of the Hindus is a moot point with most Englishmen, and with Europeans generally. I may not allow myself to enlarge on the topic here, nor is it necessary, as the following anecdote will suffice to indicate my own conclusions on the subject, impressed on me as they have been by many similar experiences of my life in Bombay.

The late Hon. Jugonnathjee Sunkersett was an orthodox Hindu, of the most uncompromising temper; but owing to some service I was able to render him in 1857, I enjoyed his entire confidence; and there is no man in whom I have ever taken a deeper personal interest, or for whom I could possibly have a more affectionate and steadfast regard. We were so intimate together that he would freely admit me to his presence while engaged in his private devotions with his domestic Brahman; only, on such occasions, I sat down just beyond the threshold of the door leading from his bedroom—in his Girgaum house—into the room in which he worshipped the ancestors of his family, and the greater deities of the official Brahmanic Pantheon; and seated there opposite me, stripped to the skin, with the officiating Brahman, and the images of his gods before him, and all the utensils of idolatrous worship, he would explain every detail of it to me as it proceeded.

Now, the great longing of his heart was that before he should see death, he might be blessed with the birth of a son to his only son, Venayekrow Jugonnathjee, familiarly called Rowjee. Years had followed years, but only girls had been born to Rowjee, and the birth of a man child began to appear hopeless. Jugonnathjee Sunkersett himself had visited every shrine in Western India, praying for a grandson, and had even extended his pilgrimages for the purpose to Benares, and I believe to Muttra and Hardwar; and he never saw me without introducing the subject into our conversation. Such was the state of matters when, being on a visit to the hill station of Matheran, and curious to ascertain the ritual of the orgiastic worship said to be enacted there by the outcast jungle tribes—chiefly cow-herds, and cutch [extract of *Acacia Catechu*, W. and A.] collectors—before the uncouth altar to "Pisnath Deo,"* [*i.e.*, Pasha-Naths, 'Pasture Lord'] in the dark grove of evergreen ironwood trees [*Anjun*, *Memecylon edule*, Rox.], at "Danger Point," on the west side of the hill, just above and to the left of "The Waterfall," I concealed myself for the purpose behind a rent in the wall of piled blocks of basalt enclosing the grove. A number of poor, abject creatures had gathered there in the dread gloom, and were about to kill a scared-looking cock, when suddenly who should come from opposite my hiding place, trotting straight into the grove, but the Hon. Jugonnathjee Sunkersett, followed by a mounted orderly (for he was a Member of the Legislative Council of Bombay), and two running peons. I thought at first that he was there, like myself, from curiosity, and was about to go forward to greet him; but the peons immediately placed themselves at the head of his horse, and he himself dismounted, and stepped up before the dreary and degraded shrine. He was a man of the Scytho-

* This is one of, if not, indeed, the most fascinating of all the words in the whole cycle of verbal affinities among the pan-Aryan languages: going back to the Sanskrit *pa* "protector," as in Gopala "the Cowherd," the Persian Padshad "Lord sovereign;" the Greek δεσπότης, "lord;" πάστη, "food," and παστός, "porridge," and πανός "bread;" Πάν, Pan; the Latin "pater" father, "patria" native country, "patronus" patron, "pastura" pasture, "pabulum" fodder, "panis" bread, Pales, Penates, and Palatinus [Mons]: and the English, (1) through German, Palgrave, foster, father; (2) through Latin by French, appanage, pantry, pasty, pattypan: (3) through Latin direct, see above, and innumerable other words; (4) through Greek, panic, patronymic, patriarch; and (5) through Persian, pasha, bashaw, bezoar-stone, *i.e.*, Pad-zahar "Lord over poison."

Aryan type, and of splendid appearance, from his shoulders upwards higher, wherever he was, than the people about him; and there he stood, in the light of a sloping ray of the declining sun that stole in between the dark trunks of the ironwood trees, long-robed, and high-turbaned, and girded round his loins, a living presentment of the "magnificent son of Akbar." But in another instant he was wringing his hands in an agony of prayer, with the burning tears streaming down his handsome, massive, but now deeply seared face; his wan, beseeching eyes looking right up towards the heavens high above that closely grown canopy of deep green, polished *Anjuni* leaves. Feeling myself to be the spectator of a scene I certainly ought not to witness, I stealthily withdrew from the spot, strolling on leisurely toward the bazaar. I had not gone on my way more than a quarter of an hour when, just before reaching the "Clarendon" Hotel, I became aware of the clatter of galloping horses approaching from behind me, and presently I heard my name being joyfully shouted out after me. Almost before I could turn round, the Hon. Jugonnathjee Sunkersett and his escort were upon me, his face lighted up in the deep-toned brilliance of the setting sun, with the most proudly radiant look of gladness.

"Oh, Settjee," I said, responsively to his mood, "you have good hope of a grandson."

"Indeed, yes," he replied, "it is just what I wanted to tell you, Birdwood."

"But," I resumed, "what solid ground have you for your assurance?"

His answer was: "Solid ground of assurance! Why God Himself has told me!"

I was astounded by the reply, and—remembering what I had secretly seen—could say nothing for my emotion; and I left him to talk on awhile like a happy child, until by devious paths—but as much as possible still pressing eastward—we at length arrived at "Alexander (now called Alexandra) Point." This Point is a little more than a mile east from "Danger Point," and commands the whole of the picturesque vale of the Chouk river, trending away south-westward, between the main mass of Matheran and its treeless north eastern spur, called, from its flinty surface, Garbut.

The twilight had now passed in the valley below us into a purple tint, rising higher and higher to the great grove [Ram Bagh, "God's Garden"] of wide-spreading mangoes, and towering *Jambools* [*Syzygium Jambolanum*, W. and A.], lordliest foliage of the woodlands of Western India, and the other fine forest trees hanging upon the east side of the hill, half way down the steep, and thread-like, rock-cut and splintered track of the old zig-zag ghat road to Chouk. The ardent purple tint had welled up to this level. Above it the umbrageous top of Matheran was flushed with the clear reflection from the refulgent orange light yet aglow in the west, turning all its exuberant leafage to a rich mystic green, of gem-like illumination. In the advancing night, thus momentarily irradiated with the still enfolded brightness of departing day, the whole enchanted mountain and valley seemed as if filled with the visible glory of over-shadowing Deity; and Sunkersett at once became silent before the profoundly solemnising, wondrous scene. Silently he watched the primitive hill-men returning by the precipitous and slippery Chouk ghat road to their scattered huts in the rapidly darkening depths of the valley below; each one, as he advanced to the head of the dangerous descent, bending lowly down, and reverently, towards the sun's far sunken flame:—

"Through Ages hymned by Hindu devotee."

The tumult of his soul was hushed, and at the last—as we turned to retrace our steps homeward—from out its depths he thoughtfully, and in his frequent oracular manner, observed: "Yes, just as our five fingers go back to one and the same arm, so all religions go back to one and the same God." Thus closed what was to prove an ever memorable day with him, and with me, for, remarkable to relate, with the completion of nine months from that date, a grandson, the deferred hope of all the years of his prime, was born to Jugonnathjee Sunkersett. The patient heavens had heard his prayer, and now their answer was not weak. And then, the great hope of his life having been fulfilled, straightway a change came over him. He was a man of strenuous energy, the most masterful natural capacity, and undisguised ambition and pride. He was not only the leader of the Hindus of Bombay, but after the death of the great Sir Jamsetjee Jejeebhoy,* of the whole Native community. But now he laid aside all worldliness, and unobtrusively and determinedly submitted himself to the great longing for death that seemed to have taken complete possession of him; saying, on my once venturing to remonstrate with him for thus yielding himself up to die, and, in so saying, using almost the very words of the Greek writer:—"It is not difficult, Birdwood, but easy; for the road is not crooked, but straight; and not up and then down, but all downward; and an unfearing man may walk it blindfold." No! He had seen the salvation of God, as sought by himself; and now all he desired was to depart in peace.

---

* How great they all were, the Bombay Parsis of that golden prime of their glory!—Cursetjee, the second Jamsetjee Jejeebhoy, the "perfect gentleman," his brother Rustomjee, the absolute incarnation of their great father's philanthropy, but not of his genius in business; C. F. Paruk; C. N. and C. R. and B. F.. and D. F. and M. F. and M. H. Cama ["the six Camajees"]; Cowasjee Jehanghir; Nusserwanjee M. Petit; Byramjee Jejeebhoy; C. M. Limjee: A. C. and H. C. Dady; D. P. and H. B. Wadia; F. N. Patel; D. F. Karaka, the historian of the Indian Parsis; Manockjee Cursetjee; Nowrojee Furdonjee; Sorabjee Shapoorjee; S. J. Sett,—all dead men now;—and brightest and best of all the sons of that morning of fresh-gathered greatness and glory, Dabadhai Naoroji, who still lives, through a third generation, in the all-cheering light of his long life of fearless and unfailing uprightness and devotion in the highest service of his exiled race and their foster country.

Soon afterward he died; and then they made very great burning for him. I thought it would have given me a cruel shock; but it was attended with none of the horrors—the awful reverberatory furnace, the repulsive, factory-like chimney, and all the soulless mechanism—of cremation in Europe. Except that milk was used instead of wine, the ritual was essentially that observed by Homer in the burial of Patroclus; and, so far from being pained, when it was all over, and I looked up into the clear and brilliant heavens above, I was soothed by the reflection that no taint of earthly corruption would ever be associated with the memory of my friend, for all that had been mortal of him was now part of the vital air and the cheering sunshine around and about me; a consideration naturally suggesting the inspiring hope that if human self-consciousness was indeed immortal, the freed spirit of Jugonnathjee Sunkersett was already with the "Father of Lights," the "Ancient of (undying) Days." It is impossible not to be deeply interested in such men, and when you know them for what they really are, not to have the sincerest friendship and admiration for them. As for their idolatry, my whole mind was changed toward it after that answer given by Jugonnathjee Sunkersett near the "Clarendon" Hotel:—"Solid ground of assurance! Why, God Himself has told me!" And this out of the mouth of a man I had just seen in that wizard wood of *Anjun* trees, praying, apparently, to a hideous heap of foully-ruddled and stinking idol stones!

Henceforward I knew that there were not many gods of human worship, but one God only, who was polyonomous and polymorphous, being figured and named according to the variety of the outward condition of things, ever changing and everywhere different, and unceasingly modifying our inward conceptions of them. We all are His offspring: and every place is His temple.

THE TUSCAN LACE INDUSTRY.

The lace industry in Tuscany was revived about thirty years ago by some manufacturers from Liguria, who had for some time the monopoly of the trade in Florence. These pioneers of the newly-revived industry had many serious difficulties to overcome. In the beginning the principal difficulty was the inability to secure women labourers. Straw-braiding was the most profitable at that time in Tuscany, and enabled the women to occupy all their spare time plaiting straw, while attending casually to their household duties. Straw-plaiting is like knitting, as it can be accomplished by the plaiter almost automatically while walking about and attending to other matters. Naturally, so agreeable an occupation was preferred to lace-making. However, the gradual decline of the straw-plaiting industry, owing to competition in production from other countries, reduced wages so materially that the women were finally compelled to take up a more profitable occupation. In the meantime various Tuscan ladies became deeply interested in the condition of these people, now deprived of their former occupation of straw-plaiting, and through personal and financial aid, taught many women the reviving trade of lace making. According to the American Consul at Florence, a school was opened consisting of some twenty pupils, under the patronage of Contessa Gabriella Spalletti-Rasponi, and having secured the co-operation of Francesco Navone of Florence, their work soon found a market. Signor Navone greatly appreciated the beautiful models which were presented for his inspection, models which had been secured from old heirlooms by the patroness, and promptly undertook the management of the school. He secured designs of the best patterns in the museums of Europe and has since had them carefully copied by the clever Tuscan women. The old "filet" lace has been particularly successful, and at the time of the last exhibition at Paris some reproductions of old "Italian filet" were exhibited with such success that the making of "filet" is now a speciality. From Florence this method of lace-making has been introduced into Venice and also into France, and the lace is now manufactured in both places on a large scale. It is particularly in request for the adornment of table linen, curtains, bed linen, pillows, &c., and the finest qualities in gowns and underclothing. Another school has also been opened in Tuscany under the patronage of Contessa Spalletti-Rasponi for the manufacture of linen embroideries. This is also under the management of Signor Navone, who has combined the Tuscan lace and embroideries most artistically. Both of these schools have prospered so remarkably within the last ten years that they now employ several hundred working women. The work is given to the women under contract, is made at home, and when finished is brought back to the school, where it is promptly paid for in accordance with an agreement previously settled. The women themselves have arranged a co-operative corporation with a capital of about £1,000, which aims to provide for the relief of the sick members, medical attendances, medicines, and to alleviate the poverty of the less fortunate and of the needy; also a provident bank has been recently opened through the payment of small sums by each working woman and 10 per cent. on the value of the work executed. Besides these two schools lace is manufactured in most of the principal towns of Tuscany, the work being promoted and encouraged by the Society of Women's Industries and by many charitable ladies. The convents also produce much beautiful lace and many simple varieties are made by the peasants. The output of this industry is for the most part sold to foreign visitors, especially Americans, who are considered the best customers; also to dealers from France, Germany, and the United States, who in former times confined their purchases to Paris, London and Berlin, now send to Florence important orders. The industry continues to grow steadily.

THE LITHOGRAPHIC STONE INDUSTRY.

The business of quarrying, and preparing for market, of lithographic stones is carried on near Solenhofen, about forty-five miles south of Nuremberg, on the main railway line to Munich. The town is an unimportant one of about 1,300 inhabitants, the stone quarries being in the hills at the back of the town, at a level of some 1,500 feet above the sea. So far as is now known, the area in which these stones are found is not more than four or five miles long by two or three miles wide. In this limited area quarrying has been carried on for more than a century, and from it practically the world's supply of lithographic stones has been obtained. The stone is a species of compact limestone of peculiar texture, and of a yellowish grey or bluish grey colour, hard bluish stones being the more valuable. It is found in layers, varying in thickness from half an inch, or even less, up to six or seven inches. The layers extend from near the surface of the ground to a depth of seventy-five or one hundred feet, or even more, and are apt to be much broken by fractures or seams, and layers of worthless rock and earth. The American Consul at Nuremberg says that in the best quarries not more than one-twelfth of the material removed is marketable stone, and much of this is of little value because of the small sizes in which it can be found clear of cracks or flaws. The quarrying is carried on by several different firms and by a company. About twelve hundred workmen are employed in the varions quarries and in the work of cutting and dressing the stone for market. The stones are lifted carefully from their position in the quarries in various marketable sizes, and are then carried to buildings near by. Here the surfaces—for some markets one, and for others both—are ground down, chiefly with coarse sand rubbed on by heavy machines, water being constantly applied during the process. One establishment has recently introduced a heavy machine fitted with a carborundum planer, which rapidly smoothes the surface of the stones as they are passed backwards and forwards under the planer. The stones are further smoothed by machinery and by hand, the edges being neatly trimmed and corners rounded. If the stones are six or seven inches thick when taken from the quarries as is sometimes the case, they are sawn through once by heavy saws fitted on the edges with diamonds, and worked by steam power. In recent years the thinner stones, which would break under the pressure to which they are subjected in printing, are, in some cases, securely cemented to other stone slabs, thus giving the requisite strength. It is a notable fact that the industry has never been a source of great profit to those engaged in it. The explanation is that the amount of dead work in the quarries is large, and the proportion of perfect stone of marketable size so small as to leave little margin of profit at the prices at which the stones are sold. It frequently happens that after a stone has been ground smooth, or perhaps been sawn through at considerable expense, a chalky vein, small pebbles, or other defects appear in the surface, greatly lessening its value. These defects become apparent when a damp sponge is passed over the surface of the stone. Those interested in the lithographic stone industry say that the demand for this product has not rapidly increased in recent years. At the present rate of quarrying they believe the supply at Solenhofen should last from one hundred to two hundred years, or even longer. The stones are at present exported to all civilised countries of the globe. France, Italy, the United Kingdom, and the United States are the largest importers, in the order named.

HOME INDUSTRIES.

Imprisonment for Debt.—The Report from the Select Committee on Debtors (Imprisonment) Bill which has just been issued is not likely to satisfy those who look upon the existing law as working monstrous injustice to the poor, or those who consider that in the interest of the poor themselves its repeal is not desirable. The Committee devoted most of their attention to a consideraton of the question of committals under Section 5 of the Debtors Act, 1869, and they find that, whilst modifications are desirable, the Act itself is beneficial. Indeed, they go so far as to say that "the law as it is appears useful and salutary, and its administration by judges and magistrates just." Elsewhere they speak of the "overwhelming advantages of procedure under the Debtors' Act," but they are constrained to admit that "it is being abused by certain classes of traders." The evidence shows that "there has been a great increase in the vendors of jewellery, expensive watches, and all sorts of publications on the terms of payment by instalments at prices often many times in excess of their market value." Here we get to the crux of the evil. The Report does not allude to it but the fact remains that much of the rubbish bought from tallymen and others by the wives of the labouring class is bought without the knowledge of the husband who, as often as not, is kept in ignorance not only of the transaction, but of subsequent county court proceedings, until they have reached the point where concealment is no longer possible, and the innocent man finds himself under an obligation to pay a sum of money he does not possess, and cannot borrow, or go to gaol. The Report recommends that the existing law shall be altered so as exclude creditors from making use of Section 5 of the Debtors' Act except in cases where their judgment debt has been obtained either for necessaries or for damages for torts. It is pointed out that the duty of deciding what are necessaries is one constantly performed by Judges in regard to infants, &c., and there is no reason to suppose that the Judges would be either unable or unwilling to perform it in cases of debt. The amendment of the existing Act in this particular should go far to rectify

the abuses now complained of. To abolish imprisonment for debt altogether would, in the opinion of the Committee, be unwise.

The Necessity for Credit.—The Committee argue strongly that the abolition of the power to imprison for debt would deprive the working classes of the credit now given them by tradesmen. They point out that Parliament has "distinctly recognised the necessity for credit," and they cite the opinion of "a very large majority of the County Court Judges," that "the abolition of the power of imprisonment for debt would tend to affect injuriously the credit now given to the working classes, a credit which in the time of strikes or depression of trade is most beneficial to those who are thrown out of work." But it is to be noted that some of the Judges are opposed to the policy of the Act on the grounds (1) that the Judges have too wide a discretion in exercising the power vested in them by the Act; (2) that the evidence upon which the Judges act is very untrustworthy; and (3) that it is very mischievous in the effect which it produces, as tending to foster a very unhealthy system of credit. It will no doubt be said by the strenuous opponents of imprisonment for debt that the Committee has attached excessive importance to the value of credit in obtaining goods, and that it is much better for the workman to wait for things he wants, other than food and clothes, until he can pay for them. The Committee would seem to be much of this opinion, seeing that they recommend that there shall be no imprisonment for debt except in cases where the judgment debt has been obtained for either necessaries or for damages for torts.

Compulsory Pilotage.—Referring to the law of compulsory pilotage, the Royal Commission on the Port of London reported that it is "so honeycombed with exceptions and exceptions to exceptions that the whole law is in a chaotic condition, and is a fruitful source of litigation and trouble." At least one of the Commissioners was in favour of abolishing compulsory pilotage, and there was much in the evidence tendered to the Commission on the point to support the recommendation. The Commission, however, were not, as a body, prepared to support such a drastic proposal, and contented themselves with recommending the transfer of the business of licensing London pilots to the London Port Authority. The Government have left all pilotage matters as they were, but they have now appointed a Board of Trade Committee to inquire and report as to pilotage in the United Kingdom. Pilotage is compulsory in 64 of the 110 districts of the United Kingdom (of which two-thirds are the Trinity House districts), and there is no power in any pilotage authority or the Board of Trade to increase the area of compulsory pilotage, though there is to diminish it. It may be taken that the Board of Trade Committee now sitting will recommend that simplification of the pilotage laws so long asked for by the commercial community.

The Premier Brewery.—The history of Arthur Guinness and Son, Limited, and of the firm that preceded it, is interesting in many ways, and is recalled by the dividend recently declared. The business represents the largest brewery in the world, its immense profits are earned without the help of the tied-house system, and it is Irish. Since the formation of the company, now some twenty-three years ago, there has been almost an unbroken increase in profits. For the year ending June 30th, 1888, the first complete year of the company's existence, the net trading profit was £791,000, and the dividend on the Ordinary stock was 15 per cent., at which it remained for the next six years. For 1895, the dividend was raised to 16 per cent., and from that figure it advanced until for the year ending June 30th, 1908, it was 27 per cent., the net trading profit for that period being £1,209,000. It appears from the accounts that for the past twelve months the results were not quite so good as before, but the dividend was 14 per cent. This seems a heavy falling off from 27, but is not so in reality. A year ago the Board decided to capitalise £2,500,000 of reserves, by which the ordinary capital was raised from £2,500,000 to £5,000,000, the new security being issued to the stockholders as a bonus. The amount of stock held by each proprietor being doubled, the dividend, supposing a maintenance of the earning power, was necessarily halved, so that the 14 per cent. of the present year represents the high-water mark of dividends, being equal to 28 per cent. on the capital as it stood last year. At the present price of 390, the yield to the purchaser is 3¾ per cent.

Cotton Mill Accidents.—Several statistical tables have just been issued by the Accidents Committee of the Master Cotton Spinners' Federation relating to accidents in cotton mills during the twenty months ended February 27 last. The membership of the Federation represents 39,530,502 spindles, and the accidents reported were 19,075. Of those who suffered them 51 per cent. remained at work, 49 per cent. left work, 7 per cent. returned within seven days, 42 per cent. were away from work more than fourteen days, and 3 per cent. over seven days and under fourteen. Out of the total accidents, 10,378 occurred in the mule room; next come 2,749 frames in card room, 1,590 card engines, 797 ring spinning, 569 weaving, 388 winding and ruling, 276 warehouse, 207 cotton room, 259 blowing room. The number of accidents to males was 14,147, to females 4,925. A table of the returns shows the ages of the injured persons. Males stand thus:—12 years, 2·38 per cent.; 14 years, 8·29 per cent.; 20 years, 3·15 per cent.; 25 years, 3·60 per cent.; 30 years, 1·84 per cent.; 40 years, 1·46 per cent.; 45 years, 1·54 per cent.; 50 years, 1 per cent.; 60 years, ·24 per cent. With the females the percentage at 14 years was 10·07; 15 years,

8·05; 16, 8·27; 17, 8·73; 20, 4·03; 30, 1·80; and 40, ·90 per cent. In both cases it will be observed that the younger the age of the worker the more accidents are reported, 14 years heading the list. A settlement has been come to with the Home Office respecting fencing carding engines.

Sale of Sailing Ships.—A large number of British sailing ships have been sold recently, mostly to Norwegian and Italian owners. The feature of the sales has been the low prices that have been accepted. *Fair Play* gives some instances. A vessel of 1,499 tons register, built in 1885, which changed hands in August, 1906, for £4,400, has recently been sold for £2,800. A steel barque of 1,352 tons register, built in 1890, was sold in April of last year for £3 6s. 7d. per ton register, whereas in June this year a steel barque of 1,346 tons register, but built in 1895, was sold for only £2 9s. per ton. A steel barque of 1,519 tons register, built in 1893, fetched £3 4s. 6d. in June last year, but last month all that could be obtained for a similar vessel was £2 9s. 8d. per ton. In July last year an iron ship of 1,742 tons register, built in 1885, realised £2 7s. per ton. Last month a German iron barque, 2,250 tons register, which was sold in July, 1907, for £7,500, or at the rate of £3 7s. 8d. per ton, only fetched £3,350, or £1 9s. 9d. per ton. These figures demonstrate the heavy depreciation which has taken place in the value of sailing ships recently, due, of course, to the great difficulty of making them pay with the freight market in its present condition.

QUESTIONS AND ANSWERS.

Readers in search of information which cannot be obtained from the usual sources are invited to make their wants known in the *Journal*, in the hope that they may be assisted in their difficulties by their fellow members.

On all communications must be written the name and address of the sender, not necessarily for publication, but as a guarantee of good faith.

Each question or reply should be written on a separate sheet of paper, and should bear such signature of the writer, and such address as he wishes to appear.

Questions which can be answered from the usual books of reference, will not be printed.

ANSWERS.

COPRA (see pp. 756 and 773).—"Malay" will be interested to hear that M. Dybowski, Director of the Paris Colonial Gardens, has been conducting experiments in the preservation of copra from mould by means of sulphurous acid. Some samples so treated in 1905 still show no signs of deterioration. In June last he made a further trial on a consignment of 3,000 coconuts imported from the Malay Archipelago. The nuts, after being cut in two, were exposed to the action of the sulphurous gases by means of the Marot apparatus. The operation has been repeated on successive batches, and it now seems to be proved that under the sterilising influence of this gas the original condition of the copra is maintained.—H. M.

THE CACAO BEETLE, *Steirastoma Depressum* (see p. 565).—The cacao beetle is a very serious enemy to cacao, sometimes causing the death of the trees. It is quite generally distributed through the West Indies and Northern South America where it is usually known as a pest when cacao is cultivated on a large scale. The egg is laid in or on the bark of the cacao tree. The larva or grub of the cacao beetle when full-grown is about 1½ inch in length and ⅜ inch in width at its largest part. It is whitish in colour. The head is dark-brown, small, and equipped with powerful jaws or mandibles with which it tunnels its way through the wood.* The segments of the body are prominent, giving the larva a wrinkled appearance. There are no legs or feet, but on the dorsal and on the ventral surface of each segment there is a small area, slightly roughened, which, being pressed against the sides of the tunnel, enables the larva to work its way along. The pupa is formed in the tunnel made by the larva. The adult is a black and grey beetle, about ⅝ to ⅞ inch in length, and $\frac{5}{16}$ to ⅜ inch in width.† The antennæ are longer than the body, the segments swollen at the apical ends, the basal segment quite stout, the others slender. The head is broad; the thorax broad, flat above, with short stout projections on each side. The wing covers are strongly ribbed longitudinally and each is tipped with a short spine. The legs are long, the femora much swollen the tibiæ slender, the dorsal joints broad, flattened, and fringed with fine hairs. The ground colour is black, the gray being due to fine whitish scales, which are easily abraded; a fresh specimen, consequently, is much higher in colour than one that has been rubbed.

Life History.—According to Mr. Henry A. Ballou, B.Sc., Entomologist on the staff of the Imperial Department for the West Indies, no observations seem to have been made as to the length of time spent in the egg, larval, and pupal stages, nor as to the season of egg-laying, and greatest abundance of adults. The damage done to cacao trees by the cacao beetle is two-fold: (1) by the adult beetle, and (2) by the larva or grub. The adult beetle feeds to a considerable extent on the tender bark of young

* In my experience the larva never tunnels in the wood, but only in the thick fibrous bark of the cacao tree.—W. M. M.-S.

† These dimensions are rather under the average. The measurements of a large cacao beetle are 1¼ inch length and ⅜ inch width.—W. M. M.-S.

plants and young twigs and branches of bearing trees. This alone amounts to considerable damage, especially in a young plantation. But not content with that, the beetle deposits its eggs in any tiny crack or crevice in the bark of the tree, a favourite spot being the junction of two branches or where a branch joins the main stem. The egg hatches, and the larva burrows into the bark, where it feeds and grows and developes. It feeds on the fibrous portions of the bark down to the cambium layer, burrowing a tunnel in the bark below the outer corky layer. The tunnel may be made in any direction. It may be worked around in a complete circle enclosing a small space of two or three inches diameter; in a line parallel with the stem of the tree or the branch; but the greatest damage is done when the tunnel is made completely around the stem or branch. The direct damage by the larva results in the weakening of the tree, caused by the sap-flow being cut off; or in the death of the branch, or the whole tree. The effect on the young plants and young branches of bearing trees by the nibbling of the tender bark by the adult beetle, is considerable; and in a short time they present a very scraggy appearance. An indirect result from the attacks of the cacao beetle, is the liability of the trees to fungus disease from the spores entering the wounds made by the adult beetle, and the larva.

Remedial Measures.—(1.) Careful inspection of the trees and destruction of the larvæ. For a few days after the larva begins to tunnel in the bark of the tree there is no outward indication of its presence. The first sign is a gummy oozing from the entrance to the tunnel, which is very small. After several days, as the tunnel increases in length, the portion left behind by the larva begins to decay and fall in, and the presence of the larva is then plainly indicated. A small pocket-knife is the most convenient tool for cutting out larvæ. The tunnel must be carefully followed up and cleaned out, and the larva killed. The sides of the tunnel must be pared smooth, and an antiseptic dressing of resin oil, or coal tar and resin oil mixed in the proportion of one to four, applied to it. The method of wire-probing, recommended some years ago, is not of much practical use; for the direction of the tunnel is not apparent, and one never knows in what part of the stem or branch the larva is located, until the tunnel is followed up by cleaning out. (2) Catching the adult beetle by hand. During the day, the beetles may be seen resting on stem and branches, where they may be picked off by hand, or knocked off to the ground with a light thin bamboo rod, and caught. They may be caught in the same way on their favourite feeding places other than the cacao trees. They may be found on the heaps of freshly-picked ripe pods, on heaps of broken pod shells, on fresh prunings of branches lying on the ground, and on the stems of the *Pachira aquatica*, a tree that is much used for shelter belts in Grenada. The boys who are sent out to catch the adult beetles do not take only those that are in the open, as described above, but employ a method of dislodging the beetles from the topmost branches and from among the foliage where the majority of the beetles are resting, hidden from sight. A sharp, short vibration of the tree, caused by stamping with the foot against the stem, causes the beetles either to drop to the ground or fly to another tree, when they are seen, followed, and captured. (3) Cacao beetles do not like dark, damp places, so that it is wise to prune so as to obtain an even canopy of shade over the stems and main branches of the trees. All open spaces in a cacao field should be planted closely with tall-growing catch crops such as bananas. The borders of a field are generally more infested with beetles than the middle portions. Cacao beetles are fond of a sunny westerly slope, and it is from these places that it is most difficult to get rid of them. They are generally more in evidence during the dry months of the year. On one estate which the writer controls, containing about 200 acres of cacao, as many as 120,000 beetles, larvæ and pupæ, are destroyed every year, and this at a cost of about £50. On a neighbouring estate as many as 200,000 are destroyed annually. It is difficult to estimate correctly the loss to an estate through the ravages of this pest for the reason that it is seldom that a cacao tree is killed outright or even in a short period by beetle attacks. Generally a branch dies off here and there and the trees, if well cared for, will recover in a short time. When the attack is persistent, the trees gradually get into a poor condition and may eventually die.—W. M. MALINS-SMITH.

Diamond Estate, S. Mark's,
Grenada, B.W.I.

OBITUARY.

ARTHUR LEE, J.P.—Mr. Arthur Lee, J.P., of Bristol and Hayes, died suddenly on the 31st ult., at his residence, 37, Woodville-gardens, Ealing, at the age of 57. Mr. Lee was head of the well-known firm of Messrs. Arthur Lee and Brothers, Limited. He served for some years on the Bristol Chamber of Commerce, and was elected President in 1901, the year in which the Royal Edward Dock was opened. He was largely instrumental in forming the Port Extension Committee, which was established in 1899, and out of which grew the Port Extension League. He was also for four years a member of the Bristol Town Council.

Mr. Lee joined the Society of Arts in 1899, and in December, 1904, he read a paper on "The British Canals Problem," for which he received a silver medal. He also occasionally took part in discussions at the Ordinary Meetings of the Society.

Journal of the Royal Society of Arts.

FRIDAY, AUGUST 20, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

H.I.M. THE EMPEROR OF RUSSIA.

At the invitation of H.R.H. The President, H.I.M. The Emperor of Russia has been pleased to accept election by the Council as an Honorary Royal Member of the Society.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

MODERN METHODS OF ARTIFICIAL ILLUMINATION.

By Leon Gaster, A.M.I.E.E.
(Editor of the *Illuminating Engineer.*)

PART III.*

High-pressure Gas-lighting.

I now come to one method of improving the efficiency of incandescent gas lighting, which, perhaps more than any other, has led to immense developments in recent years, namely, the use of high-pressure gas. There is no inherent advantage in using high-pressure gas except for the purpose of producing a more intimate mixture of gas and air coupled with a greater velocity of gas issuing from the burner, and therefore increased flame temperature with more perfect combustion.

Time will not allow me to enter into details as regards the many different systems of compressing the gas for subsequent use in this way, but I may make mention, among others, of the Scott-Snell, Sale-Onslow, Millenium, Grätzin, Pharos, and Keith and Blackman systems.

In the last-named system, of which I am privileged to show you quite the latest development to-night, a very compact type of compressor is used, which is driven by electricity, water, or from a belt, as may be desired.

Fig. 28.

Grätzin Inverted High-pressure Lamp.

The result of leading gas into the burner at a high pressure is a great gain in efficiency, and pressure as high as 55 inches of water is actually in use at the present day. For instance, the illumination of Kingsway and

* The Course consisted of four lectures, delivered on February 15th and 22nd, and March 1st and 8th. In re-arranging the material for publication in the *Journal*, the lecturer has preferred to divide it into six parts.

Aldwych, on the Millenium system, utilises a pressure of 54 inches, while the Sale-Onslow system at the new Victoria Station, uses 50. The new Keith inverted lamps just installed in Fleet-street are also run at a pressure of about 50 inches. It is true that the Salzenberg lamp, brought out in Germany, utilised a pressure of as much as one atmosphere, but it does not seem to have ever developed into a practical condition.

One point of interest in connection with the Keith apparatus, is a lubricating device, by means of which the compressor, once charged with oil, does not require a fresh supply for some considerable time. The compressor shown at this lecture is fitted with this automatic lubricating device.

The main point of advantage claimed for the inverted lamps, of course, is their high candle-power, as much as 73·6 candles having been obtained by some tests with ordinary town gas. However, only 60 candle-power per cubic foot is claimed by the makers. The lamps are made in all sizes from 60 candle-power to 1,500 candle-power, with single burners.

The high efficiency claimed is said to be obtained to a large extent by means of a pre-heating device, whereby the gas and air mixture is passed through a heater fixed on the bottom of the burner tube, as near the mantle as possible. It takes the form of two shallow cones, fixed base to base, with a diaphragm between, perforated at the outer edges. This has the effect of spreading out the mixture of gas and air over a large area of highly-heated surface before reaching the nozzle. The heating of the gas and air mixture takes place progressively, for as the mixture gradually moves forward it is brought into contact with surfaces which are more highly heated than those it has just left. At the same time, the heater has the effect of taking heat from the nozzle, and so prevents it becoming too highly heated at the tip.

An additional effect is obtained by heating the secondary air supply as highly as possible before coming in contact with the mantle. By this means as much of the waste heat as possible is utilized to give a regenerating effect.

To overcome the resistance of the burner, due to the large expansion of the heated mixture, and the high velocity at which it is necessary for the mixture to issue from the nozzle, a 4 in. Mercury Column Gas Pressure is required.

The larger lamps, if desired, can be arranged with "Automatic Distance Lighters," which enable them to be lighted and extinguished by the increase or decrease of the pressure occasioned by the starting or stopping of the compressors, or any other method of controlling the pressure at the lamp.

Fig. 29.

Keith Inverted 1,500 C[illegible] High-pressure L[illegible]

The largest lamp which [illegible] at this lecture is fitted with this [illegible]istance lighter device.

The advantages of hig[illegible]ighting where high candle-power [illegible]red are very obvious, though the[illegible] few inconveniences attached to the [illegible]

No doubt experience is teaching us to reduce the percentage of mantles broken in this way. Some particulars of the breakage of mantles and globes occurring when lamps are switched on suddenly, and the methods by

which these troubles were avoided in the case of high-pressure inverted mantles used in Berlin, have recently been given by Drehschmidt. (*Illuminating Engineer*, Vol. I., 1908, [illegible]51; *Journal of Gas Lighting*, Aug[illegible], 1908.) Mantles, however, are as a[illegible] specially strongly woven or even doub[illegible] order to resist high-pressure.

One point of some importance in the design, of high-pressure incandescent gas lamps, has been the adoption of lanterns containing two or three distinct mantles, giving in all, the same candle-power which a single big mantle would do. This method has several advantages. For one thing, a small mantle is in general not so liable to injury, and lasts longer

Fig. 30.

Illumination of Fleet-street by Keith High-pressure Gas Lamps.

than a large one; it may, in addition, be more efficient. Again, when three mantles are used, the breakage of one of them is not so serious, as there are two healthy mantles left burning. When there is but one mantle in the lamp, on the other hand, an accident to it puts the light out altogether. Yet another merit of the three-mantle arrangement is that it is possible, at a certain hour at night, to arrange for the extinguishing of two out of the three, thus effecting a saving without plunging the streets into complete darkness. This method of partly extinguishing the lamps is now used in Berlin, and other towns in Germany.

The Relative Merits of Pressure-Gas and Pressure-Air.—A considerable amount of discussion has recently taken place round the question of the relative merits of using compressed air or compressed gas in the burner; both, as we have seen, are capable of leading to the intimate mixture of gas and air which we desire to produce. Klatte, of the Pharos Company, has strongly recommended the use of high pressure air, urging several advantages. (*Illuminating Engineer*, Vol. I., 1908, p. 956, and references.) For instance, the original gas pipes can be used, and in the event of anything going wrong with the high-pressure air system, the light is diminished only and not extinguished.

When we use high-pressure gas, on the other hand, an accident to the compressor may have serious consequences, and the tendency to leakage is, of course, greater than with low-pressure gas. In addition, it is urged that the necessity for employing special meters for high-pressure gas, and other inconveniences in supplying the system to private consumers, is avoided by the use of high-pressure air. On the other hand, high-pressure air systems require two pipes, an arrangement which is not always convenient. It is interesting to recall that the method was adopted many years ago by the United Kingdom Lighting Trust in this country, and is still in use at the present day.

Another system to which reference may be mede is the Selas, in which a mixture of gas and air is compressed and supplied to the burner The system involves the mixing of gas with air, and therefore essentially differs from ordinary high-pressure systems. The gas, coming through the meter, passes into a mixing apparatus, in which it is automatically mixed with air in the proportion of two parts of gas to three parts of air, and this mixture then passes into a compressor, from which it is delivered into the service-pipes at a pressure of 10 inch water-gauge. The chief advantage claimed by the Selas system is its great economy and the variety of burners. The upright burners range from 25 up to 5,000 candle-power, the efficiency being 50 candle-power per cubic foot per hour. This efficiency is claimed to be realised even with the smallest burner. The pressure being only 10 inch water, any ordinary pipes may be used, and the leakage, if there be any, cannot be greater with Selas at 10 inches than with ordinary gas at 2½ inch pressure.

Self-contained Highly Efficient Lamps.

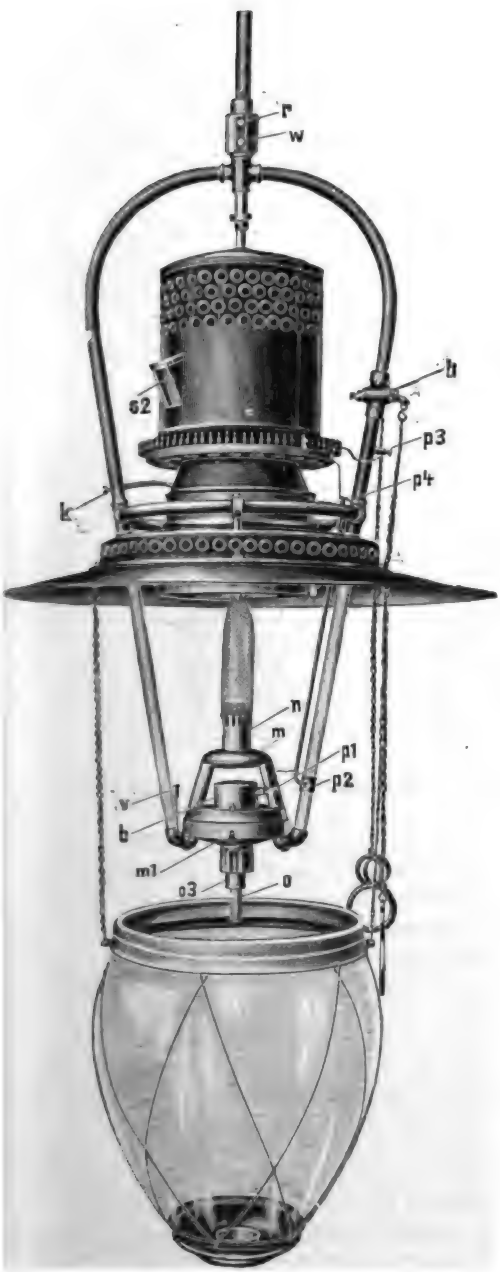
In any case, whether we use high-pressure air or high-pressure gas, it is usually necessary to make some alteration or addition to the system of mains. Attempts have therefore been made to introduce into ordinary gas lamps local pressure raising or regenerative devices. Thus Scott-Snell many years ago devised means of pre-heating the air supplied to the burner and securing a forced draught. Lucas sought to produce an increased draught by the use of special long chimneys, but this simple device rendered the lamp inconveniently long. More recently, the same lamp has been modified by the ingenious application of a thermopile, the junction of which is placed near the flame and supplies current to a small electrically-driven fan at the base of the lamp; while another improvement consists in a device to enable the junction of the pile to get heated without being actually in the hot zone of the flame. It is stated that the thermopile will last 1,000 hours before it requires renewal.

It will naturally be recognised that the heat-resisting properties of the metals used in the thermopile are the chief consideration, and therefore metals like copper, nickel, and aluminium are selected, and the life is considerably prolonged. The current required is but small.

As a result of the air sucked in by the electric fan at the base of the burner, a flame of very high temperature and a correspondingly high efficiency is obtained. At the same time the cool air drawn in by the fan keeps the base of the burner and the actual working parts cool, and promotes their wearing power.

For this lamp it is claimed that a minimum candle-power of 1,200, obtained at the consumption of only 30 cubic feet of gas per hour, is arrived at. It is also pointed out that the

FIG. 31.



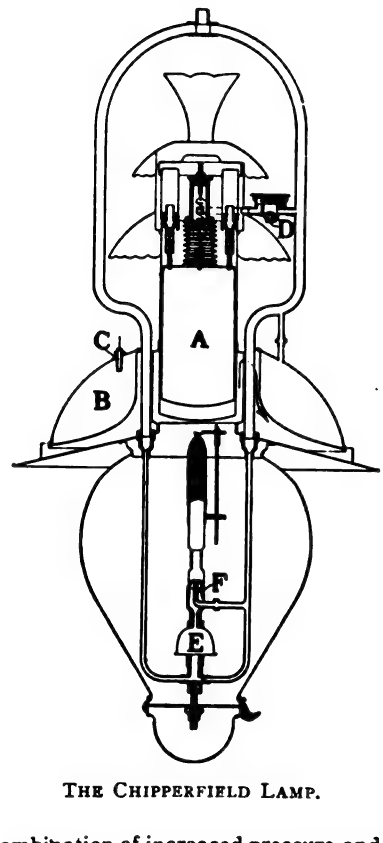
DETAILS OF LUCAS THERMOPILE LAMP.

[The gas enters through the regulator at *r*, passes through the cock *h* into the mixing chamber *m*, and finally through the burner at *n*, and so, after heating the mantle, up the chimney. In this is fixed the thermopile *t*, the current generated in which is carried by the wires p_1, p_2, p_3, p_4, to *m*, a small electro-motor, rotating about a vertical axis at a speed of 2,000 revolutions a minute. This motor is coupled directly on to a small fan, which creates the required draught.]

lamp is of comparatively small size, absolutely self-contained, and can be used with any pressure and quality of gas off the ordinary supply pipe.

Yet another type of portable high-pressure lamp is the Chipperfield, which utilises what is equivalent to a small hot-air engine placed above the burner; this automatically pumps air under pressure into the heated reservoir,

FIG. 32.



THE CHIPPERFIELD LAMP.

the combination of increased pressure and pre-heating resulting in a considerable increase in efficiency.

In the top of this lamp there is a movement worked by the waste heat of the burner which causes the air to expand in the cylinder, A, thereby forcing the displacer to rise.

Attached to this displacer are two valves which, when the air displacer is at the highest point, exhaust the expanded air, and when the displacer is at its lowest point draw in cool air. Attached to this displacer there is also a metal concertina which, when on the down stroke, draws in air through an inlet and outlet valve at D, and on the displacer rising the concertina compresses the said air, and passes it back

through the above-mentioned valves to a reservoir, B, which takes all the fluctuation out of the light.

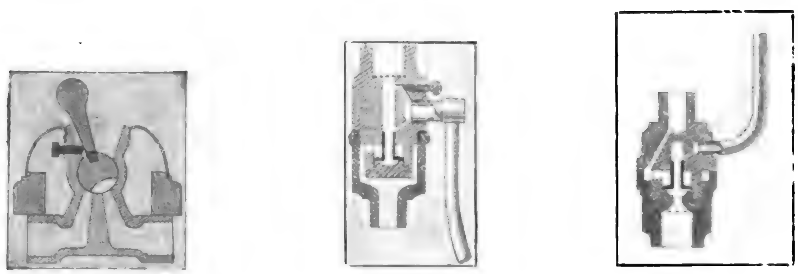
The reservoir is fitted with a blow-off valve, C, adjusted to a pre-determined pressure of 32 inches. The lamp is fitted with an air and gas nipple of special design, F, which enables the gas to be regulated by a turn of the cap. The air is regulated by a sleeve on the Bunsen tube. The movement can be replaced in less than five minutes by simply disconnecting one union.

[Since the exhibition of this lamp, fitted with the upright mantle, at the lecture, I have been given to understand that the firm are bringing out an inverted type from which good results have been obtained.]

Wolf gas is yet a third system of a kindred nature (*Illuminating Engineer*, Vol. I, 1908, page 681); it consists principally of such hydro-carbons as ethylene and ethane, and is claimed to be influenced to an exceptionally small extent by external temperature.

These liquid gaseous illuminants claim exceptionally high calorific value, oil gas being stated by Mr. F. D. Marshall to yield 8,000 to 10,000 units, and Blau gas over 13,000. This may account for the extremely high illuminating efficiency claimed, for it is stated that the equivalent of over 100 candle-power per cubic foot per hour has been obtained by using Blau gas.

FIG. 33.



DETAILS OF THE NORWICH DISTANCE-LIGHTING SYSTEM. (G. HANDS AND CO.)

LIQUID GAS SYSTEMS.

I may next say a few words about a system of gas lighting which has recently come into prominence, namely, the use of liquid gas of various kinds. To this I may refer again in my next lecture. Compressed gas of this description is mainly employed in cases in which portability is extremely desirable—for lighting railway carriages, &c. The coming of the inverted mantle and the possibility of making mantles which would withstand the vibrations of trains has led to considerable development of this method.

One of the older systems in this country is the Pintsch oil gas system, in which oil gas is subjected to a pressure of about 6 to 7 atmospheres per square inch.

The Blau gas again is a special liquid illuminating gas produced by the distillation of mineral oils, such as crude petroleum; the gas is in this case compressed at the exceptionally high pressure of 100 atmospheres, 20,000 litres being reduced to the bulk of 50.

AUTOMATIC IGNITION AND EXTINCTION.

I now come to one development in gas lighting which will be recognised to be of exceptional importance at the present day, namely, automatic ignition. If there is one respect in which electricity has claimed to possess a great advantage over gas lighting, it has been the ease with which electric lamps are lighted or extinguished. Naturally, therefore, efforts have been made to extend the same facilities to gas lighting.

One of the simplest systems of this kind has been the arrangement, employed in the Norwich system of gas lighting, of which I am enabled, through the kindness of Messrs. G. Hands and Co., to show you an example to-night.

In this system no air tubes or electrical wires are required. The switch itself, being in the form of a bye-pass cock, is inserted in the supply pipe to the fitting which it is required to control, and an automatic valve is applied to the nose-piece of the fitting, for the purpose of directing to its proper course the small quantity of gas which is required for a pilot light.

Thus the actual gas pressure supplied controls the valve in the nose-piece of the fitting, and turning on the full pressure is sufficient to enable the lamp to light up. The manipulation of the lamp inserted in the pipe provides either a bye-pass or allows the gas to flow freely to the burner. The system claims to be a very permanent one, only requiring trifling attention. In this case the resemblance to the ordinary tumbler electric switch is strikingly carried out.

Pneumatic and electrical methods of ignition recently formed the subject of a valuable paper by Mr. T. J. Litle, at the Second Annual Convention of the Illuminating Engineering Society of the United States (the *Illuminating Engineer*, Lond. Vol. I., 1908, p. 1025). The pneumatic system, he said, was not usually supplied to the ignition at distances of more than twenty yards, which is, of course, amply sufficient for an ordinary household, though special pressure-raising devices may be used to act on a lamp in a very large hall. Of course, the pneumatic systems pre-suppose the use of a pilot flame. In passing I may refer to a method of utilising a single pilot flame for the cluster of several mantles in the same lamp.

Another method which has been the subject of a considerable amount of experiment is electrical ignition. According to the usual system the kindling is accomplished by a jump-spark from an induction coil or magneto-generator. At the discussion of the paper by Mr. Litle just referred to, many divergent expressions of opinion were to be noted, some professing to have found the system completely satisfactory, while others found it very irregular.

It need hardly be pointed out that this is one of those cases in which the gas engineer has found it to his advantage to study the kindred subject of electricity. In the discussion of Mr. Litle's paper it was very generally agreed that previous failures had been largely due to deficient insulation. Failures may also be due to a spark occurring in the wrong position in the burner, and, therefore, failing to ignite the gas.

I am pleased to say that, by the courtesy of Mr. George Keith, I am able to show you the automatic electrical ignition used with the newest Keith lamps, which is, I believe, exhibited here in public for the first time. This latest form of controlling and ignition can be performed electrically, and possesses several novel features, one of the advantages being that it dispenses altogether with the use of bye-passes.

The arrangement on the lamp consists of a tubular body which is part of the down-stem, containing a permanent magnet fitted with a brass valve at the bottom, which drops into a seat and holds it tight by its own weight against gas getting into the burner. Above this permanent magnet is fixed the core of an electro-magnet, the coil of which is fixed on the outside tube. Conducting wires from one pole of the necessary battery fixed in a convenient spot are taken to each lamp, the return current passing through the gas-piping itself. The permanent magnet is therefore lifted or repelled by the passing of the current in certain directions, accordingly as the gas is required to be on or off in the lamp, and at the same time the same current passing through the platinum filament contained in a small chamber fixed on the burner nozzle ignites the gas.

It is hardly needful to point out that any automatic system for lighting interiors must be absolutely reliable. A very wide field, however, has been opened out in the automatic control of public lighting in the street.

Street lighting forms an essential part in the revenue of gas works, and therefore it demands a great share of consideration, not only on account of this revenue, but also because of the safety of public thoroughfares. This is particularly the case on account of the improvements made in electric lamps and the consequent increased competition of electric light.

With electric illumination all, or nearly all, lamps are operated from a central point. This arrangement makes it possible, if desired, to deviate at any time from the fixed lighting schedules or arrangements entered into with lighting authorities, making street lighting independent, and applicable to existing circumstances, due to meteorological and local requirements. These conditions will have to be transferred to gas, if gas wishes to maintain permanently its acquired position as a popular illuminant in competition with its rival, electricity. Various forms of apparatus and devices were resorted to a few years ago for the purpose of lighting and extinguishing street lamps. They utilised either electricity, gas pressure, or clockwork. Street lamp lighting by electricity has not yet found favour, on account of the great expense connected therewith, whereas the employment of gas pressure for operating distance-lighting has proved itself very reliable and free from objections.

A few years ago, the first experiments were made to use additional gas pressure for operating distance-lighters.

Experiments in the construction of pressure distance-lighters to operate by pressure waves led to the result of constructing two main kinds, one with a diaphragm, and one with a float or cup, on which the wave can exert its force. Some particulars of the use of the Alder and Mackay system in Tipton have been given by Stephenson (*Journal of Gas Lighting*, March 10th, 1908), who found that a very great saving in labour and in breakages of mantles, rods, and glasses was achieved by the introduction of the system.

In this case an increase of pressure of 1 in. to 1½ in. was maintained for about half a minute to a minute and a-half, and the wave seemed to travel practically instantaneously. An interesting result of this pressure-raising method is that at a certain hour of night, when the public lamps are extinguished, the lights of private consumers are also temporarily affected. It is stated that no objections were raised on this score; indeed the consumers rather welcomed this gratuitous information that midnight was at hand.

A very interesting automatic lighting and extinguishing apparatus for street lamps, is that of Dr. Rostin, which is employed very extensively in this country. In this case, the automatic arrangement consists of two valves which float in a special non-freezing and non-evaporating mixture of glycerine and water. A certain definite increase in pressure beyond the point to which the inlet valve is adjusted, has the effect of admitting the gas to the working bell, which turns on a main cock. It will be noted, however, that if afterwards the pressure falls a small amount, as may quite likely happen when it is lowered after lighting time, a rise before midnight does not have the effect of lighting up when the lamps are not supposed to work.

It may be remarked that the valves in this case have no actual work to do, and no friction to overcome, and therefore work quite correctly, the actual pressure on the cock being accomplished by the gas let into a bell, and pressing on a suitable diaphragm.

Another modern type of automatic control, depending on a wave of pressure, is the Bamag system, which I am also privileged to show here to-night. In this case, the exact pressure at which it is desired that the apparatus should regulate, may be adjusted by setting the pointer on the dial, and the apparatus can be

Fig. 34.

The Rostin Automatic Distance Lighting and Extinguishing Apparatus.

controlled either by a rising or falling wave of pressure.

Clockwork systems controlling street lighting, by which the lamps are turned out and lighted at a pre-determined hour, have also been utilised very frequently. These methods have certain advantages, being, perhaps, more reliable than others depending on a wave of pressure.

On the other hand, they have the disadvantage of being too automatic; they turn on and off the light at a certain hour, but on an exceptional occasion, for instance, when a fog is on, they, of course, do not take account of the fact, whereas an instrument controlled from the station can be made to do exactly what is wanted. Such clockwork methods have, however, also found a field for advertising signs, which can be left burning on the premises without the shopkeeper or his assistant being actually there. (Figs. 36*a*, 36*b*.)

Perhaps, in passing, reference may be made to the discovery of Welsbach, that a mixture of finely divided iron and cerium in suitable proportions yields sparks when rubbed; it is anticipated that an automatic lighting device may be based on this principle, but the apparatus is not yet in a commercial stage.

[Since the delivery of this lecture a communication by Wunderlich has appeared, describing the practical application of a very similar process, *Journal für Gasbeleuchtung*, May 15.]

Before leaving this subject mention may be made of the various attempts that have been made to try to produce some apparatus which should be absolutely self-lighting. It has long been known, for instance, that spongy platinum, when exposed to a stream of gas, becomes heated, and may kindle the latter into a flame. Unfortunately, the heat of the flame tends soon to injure its quality. For this reason a device was adopted by means of which, as soon as the flame was lighted, the spongy lactive material was caused to fly out of the heating area. Even this, however, soon deteriorated, owing to the effect of atmospheric moisture, &c., and other causes.

To-night I have on exhibition one of the newest types of self-lighting gas mantles of this kind, which is said to be exceedingly permanent if certain illuminatory precautions

FIG. 35.

PHOTOGRAPH OF WINDOW ILLUMINATED BY SYSTEM SHOWN IN FIG. 36a.

in the use of the mantle are taken. I am informed, however, that some difficulty may be experienced in applying this device to very poor gas containing but few hydro-carbons. However, we can regard this only as an interesting attempt to solve the problem.

FIG. 37.

SELF-LIGHTING MANTLE. (J. MAYER.)

STREET LIGHTING.

It may, perhaps, be expected that I should say a few words about one use for gas lighting which is receiving considerable attention at the present time, namely, street lighting. I have already referred to the recent developments in the City of London, where the Keith high pressure inverted lamps have just been installed in Fleet-street. An interesting detail of this installation is the manner in which the lamps are attached to the house by means of brackets, instead of being suspended on lamp-posts.

An analogous method of avoiding the use of lamp-posts is, of course, the suspension of flame arc lamps above the roadway on wire cables in Cannon-street. This method is now very widely employed on the continent. It has several obvious advantages but is not so easily applicable to gas lamps, though, as will appear later, it has recently been used in Germany.

The competition between high-pressure gas and flame arcs for street lighting has been very keen both here and on the Continent. Many of you may know of the report issued by Mr. Voysey on the lighting of the City of London (*Illuminating Engineer*, Vol. I, 1908, p. 605). Whatever we may feel as regards Mr. Voysey's conclusions, I think it is of interest to observe that these results are fundamentally based on actual measurement of illumination in the streets.

In Berlin an interesting situation is presented by the fact that the gas generating station is owned by the city, while the electric lighting companies are private, but pay handsomely for their privileges, and are, therefore, a valuable source of income to the city. Recently the use of the Blondel flame arcs under the hands of Dr. Bloch has given rise to very good results, while Dr. Drehschmidt has recently described the developments in high pressure in inverted gas lighting which kept step with the development in electricity in this city.

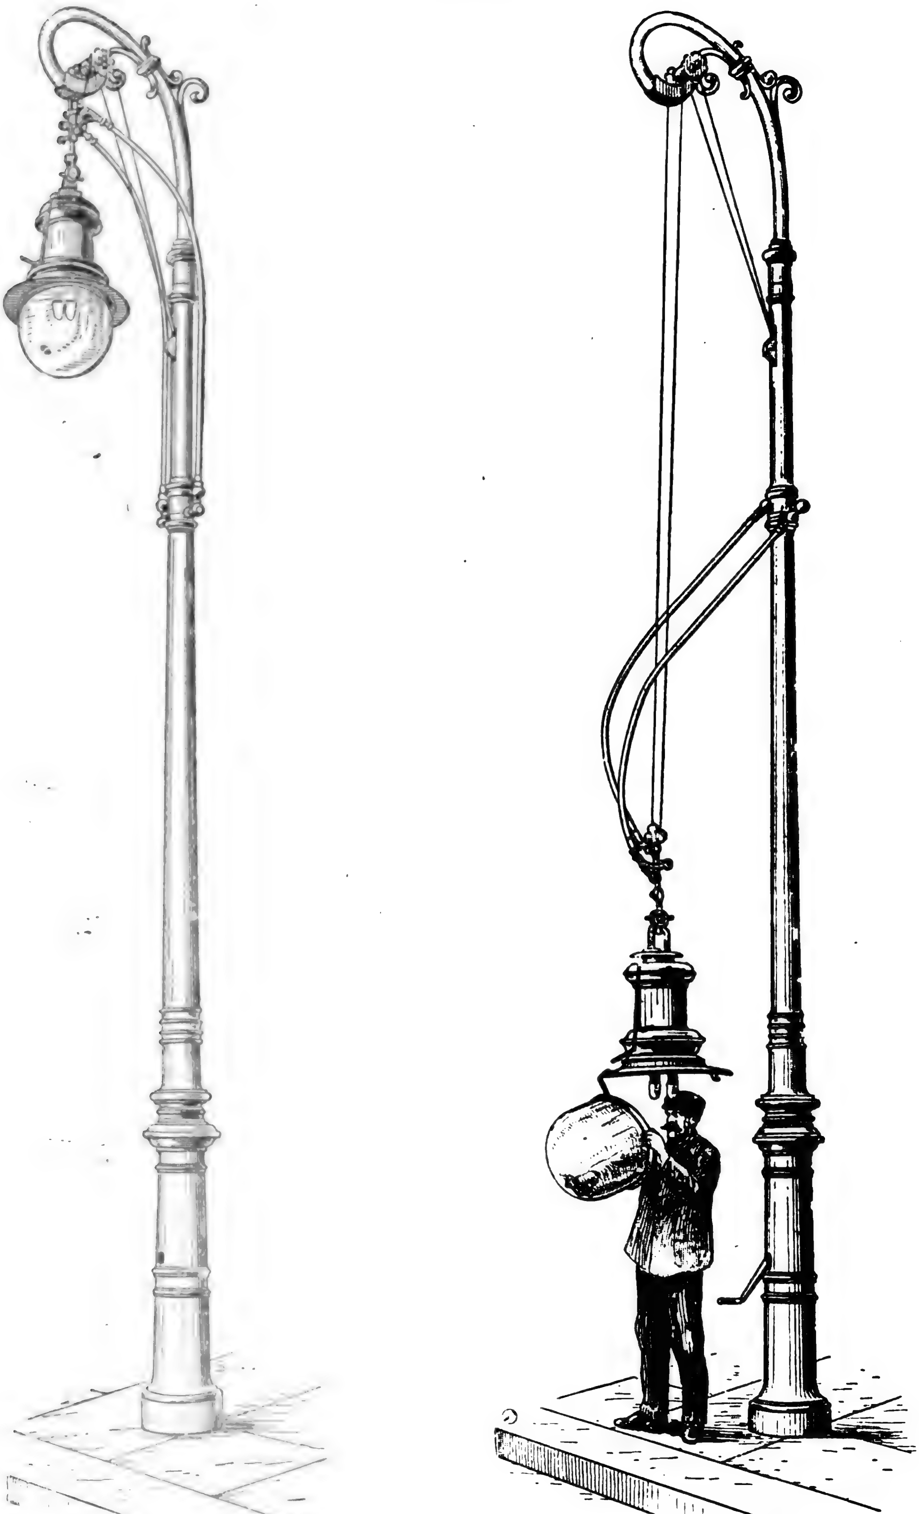
A very valuable precedent has recently been established by the authorities in the city of Boston, U.S.A., who dispatched experts connected with various systems of lighting to make a tour of the Continent and report on existing methods of street illumination, before taking any decision on the matter. It need hardly be pointed out how essential are the services of *experts* in order to prepare reliable data for the guidance of municipal authorities, and the city will doubtless reap the benefit of their foresight.

[Since the delivery of this lecture a deputation appointed by the Streets Committee of the Corporation of London has paid a visit to the Continent, with the object of examining the lighting of the chief cities in Europe, and has published its experiences. The method of street lighting preferred by the deputation consists of inverted high pressure incandescent gas lights, centrally placed in the street and equipped with raising and lowering apparatus; where this is not possible electric lighting is recommended.

The suggestion that high pressure incandescent gas lamps should be raised and lowered for attention in the same way as arc lamps is somewhat novel, and has given rise to some surprise; I have nevertheless recently seen and had an opportunity of inspecting a form of apparatus which is now being manufactured by Messrs. Ehrich and Grätz, in Berlin, and which is said to enable this to be satisfactorily accomplished.

I have also had an opportunity of observing

FIG. 38.



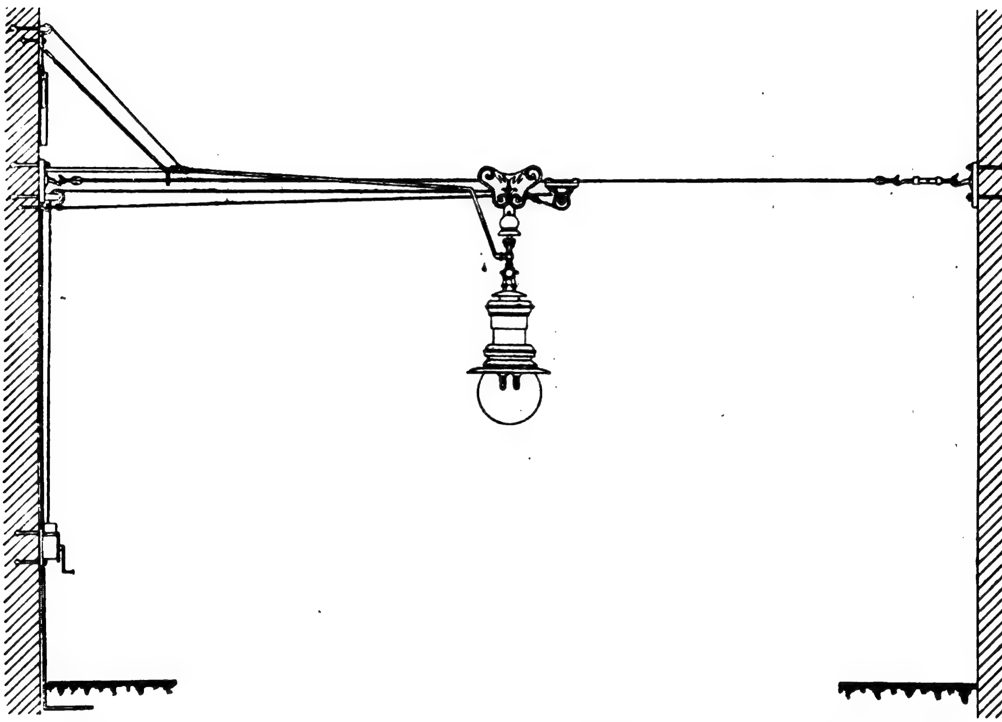
ARRANGEMENT ENABLING HIGH-PRESSURE GAS LAMPS TO BE LOWERED IN THE STREETS TO RECEIVE ATTENTION. (MESSRS. EHRICH AND GRÄTZ, BERLIN.)

this system in the experimental stage in the streets of Stuttgart, in Germany. I have, however, been informed by several Continental experts that the method is not yet so satisfactory in the case of high-pressure gaslighting as it has been found to be in the case of electric arc lamps. A considerable amount of experiment has been necessary in order to make the arrangement practicable, and to avoid possible leakage at the joints, deposits in the piping in winter, corrosion, &c. Formerly a flexible tube, enabling the lamp to be lowered, was used, but more recently it has been found preferable in Stuttgart to employ a jointed gas-pipe, and to arrange for the lamp being brought to the side of the street, before being lowered. In Stuttgart, both high-pressure gas and high-pressure air systems have been used, the latter, however, necessitating the use of two distinct pipes to convey the gas and air respectively.

In adopting a system of this kind, however, it must be borne in mind that the polar curve of light-distribution of flame arc lamps differs considerably from that of incandescent gas-lamps, and that the method and height of suspension that is found satisfactory for the one, may not be equally so in the case of the other. And, in addition, it may be suggested that when it is found desirable to instal high-pressure gas lamps fairly low down in the streets, they should be equipped with some form of diffusing globe; otherwise the effect is apt to be glaring. It may be mentioned that this deputation did not contain any experts connected with the various methods of lighting examined; therefore, while recognising the importance of the precedent established by municipal authorities studying for themselves systems of illumination, one must be cautious in advocating too sudden and extensive modifications in existing systems of lighting the streets of London, as a result of their experiences.

It need hardly be said, moreover, that it would be unwise to attempt the lighting of all varieties of streets on any uniform special plan such as that outlined above, and it is to

FIG. 39.



METHOD OF SUSPENDING HIGH-PRESSURE INCANDESCENT GAS LAMPS ABOVE ROADWAY

(The lamp is shown hung across the road in its normal position. When requiring attention, the jointed piping enables the lamp to be drawn aside to the pavement and lowered.)

Fig. 40.

be noted that further experiments in the streets of London are to be conducted before any final decision is taken. The question is who ought to undertake these tests, so that we may accept the results as unbiassed ?]

A Calorific Standard.

Prof. Morris in a recent article suggested that entirely different results would naturally be obtained if the gas used was London gas, or the much richer gas employed in Edinburgh. This leads one to comment on what is now felt to be a rather curious anomaly in the present conditions of gas testing, that we still test gas in terms of its illuminating value, while, as a matter of fact, now that incandescent gas mantles are so widely used, it is the calorific value in which we are mainly interested.

The question has already arisen how far we shall continue to abide by the legislation of the past, or whether we shall not eventually entirely abandon the test of illuminating value, and be content with producing non-luminescent gas of a high calorific value producible at a distinctly cheaper rate.

This matter has been the subject of much discussion in this country, and very careful consideration in the United States, where a recent Committee of the American Gas Institute reported upon it at great length. I believe that in Chicago a calorific standard has already been set up.

In this country, legislation of recent years has made several concessions to this point of view. For instance, in 1900 the South Metropolitan Gas Company succeeded in promoting a Bill authorising them to reduce the illuminating value of their gas from 16 to 14 candles, and last year a notable step was undertaken by the Edinburgh and Leith Gas Commissioners in agreeing, in accordance with Mr. Herring's recommendation, to reduce the candle-power of the gas in that town from the high value of 20 to 14. The Gas Light and Coke Company have also now definitely recognised a calorific test in addition to tests of illuminating power.

Although this method of insisting only on an illuminating value of gas, when calorific value is all important, may seem rather strange, yet there are certain difficulties which will probably lead to only a gradual change in existing regulations. For instance, it is urged that one of the chief advantages of adhering to a standard of illuminating value is that any appreciable percentage of inert gas is immediately detected by the decrease in illuminating value.

Although an immense amount of work has been done on the subject of gas calorimetry in this country, it seems to be admitted that the process is far from being such a simple one as the illuminating test at present employed, and that until recently sufficiently accurate instruments for the purpose were not available. However, there are indications that a change will soon come.

In Germany, too, I was given to understand by Dr. Drehschmidt that calorific tests are regularly undertaken by the gas company in Berlin, and a systematic record of the qualities of the gas, in this respect, constantly kept, in order that any deterioration in heating value may be immediately recognised and detected.

I notice, however, that Herr Lebeis, in a paper recently read in Berlin, and reported in the *Journal für Gasbeleuchtung* (August 14), remarks upon the fact that in different districts both the pressure and the calorific value of the gas supplied are often found to differ very considerably; consequently a type of burner which is satisfactory in one locality may not be equally so in another. The same point is emphasised in a recently published address of Mr. H. O'Connor (*Gas World*, Aug. 14), who indeed goes so far as to assert that "a burner which was a good one in one town might be an absolute failure in another."

Lebeis describes an interesting modification of the incandescent burner which is intended to avoid this difficuly, and which he terms the "Aerostat." This consists essentially of an arrangement covering the inlet holes of the burner which contracts and expands with the heat, admitting more or less air, and automatically maintaining the most favourable conditions for combustion. In this it seems to resemble the thermostat described by Litle and Whitaker in the United States. (See p. 786). Besides allowing for differences in calorific value and pressure of the gas supplied, this arrangement is also intended to compensate for the alteration in the conditions which prevail when the burner has only just been lighted and is cool, and those which are present when it has reached its normal hot state. These new burners are made for small candle-powers, as low as 33 mean hemispherical candle-power.

[This matter of a calorific standard has just been commented upon in the annual address of the President of the Gas Institute, who foresees its ultimate adoption. A very interesting

paper by Mr. C. Forshaw, delivered on this occasion, illustrates most forcibly the fact that there are other factors, apart from calorific value, such as flame-temperature, shape, and volume, which affect the performance of an incandescent gaslight. Mr. Forshaw also demonstrates how the incandescent illuminating power of two gases, hydrogen and carbon monoxide, may be very different under apparently similar conditions, even though both have approximately the same calorific value. Mention may also be made in this connection of the exhaustive experiments of M. Sainte Claire Deville, who has recently published an article in *The Illuminating Engineer*, July, 1909, summarising his views on the subject.]

Relations between Company and Consumer.

In my first lecture I referred to the valuable work of the Boston Edison Electric Illuminating Company, in assisting the consumer and undertaking to advise him how to use his lights to the best advantage.

This attitude has also been adopted by gas companies in the United States, and, I am happy to observe, by the most enterprising companies in our own country as well. For instance, the Gas Light and Coke Company and other companies here fully realise the necessity of keeping the consumers thoroughly satisfied, and undertake for a small charge to maintain their gas burners and mantles in a satisfactory condition.

The educational value of such a provision is proved by the fact that consumers not infrequently eventually learn something of the adjustment of burners and mantles from the company's representative, and prefer to save money by undertaking the supervision themselves. On the other hand, it must be confessed, that they do not always realise the real economy of renewing mantles promptly as soon as the candle-power has begun to fail.

The Gas Light and Coke Company make a practice of renewing mantles when their initial candle-power has dropped 25 per cent. This usually occurs after about 200 hours burning. We have thus an interesting analogy to the "useful life" of glow lamps, which is usually assumed to be the time that elapses before their candle-power is reduced by 20 per cent. from their original value.

The Company still undertake the supervisio of some 200,000 burners, and it is probable that very many more customers will now look after their own installations who were originally educated by the Company to do so. It is also interesting to learn that the Company make a practice of thoroughly testing mantles supplied to customers, by a rigid specification involving both tests of life and candle-power, and showing resisting power against vibrations.

In my present lecture I think I have said sufficient to indicate the exceedingly wide scope and scientific nature of the problems with which the gas profession has now to deal, and the enterprising manner in which many of them have been met during the last few years. In conclusion, I would like to emphasise one point which follows as a natural consequence, namely, the necessity for making provision for the adequate education of the young men of the future.

During the last year a great figure in the gas industry, Sir George Livesey, has passed away, and I think some mention might be made on this occasion of the admirable decision of the Gas Institute, and those who attended a special meeting with the object of honouring his memory. It was decided to create a professorship of gas engineering in his memory at Leeds University; the necessary arrangements have now been made, and this professorship may be regarded as an accomplished fact.

I hope that this will lead to the prosecution of many researches of great value to the industry with which Sir George Livesey was so long associated, and that manufacturers will promote the welfare of the scheme by encouraging those who take advantage of these facilities.

DEW-PONDS.

The August number of the *Geographical Journal* contains an interesting paper by Mr. Edward A. Martin, F.G.S., on "Dew-ponds," the subject, it will be remembered, of a paper read before the Society last session, by Mr. George Hubbard, F.S.A., which led to a considerable amount of correspondence in these columns. While agreeing to a large extent with Mr. Hubbard as to the general principles on which these ponds are constructed, Mr. Martin differs from him as to the precise process by which they obtain that portion of their supplies which comes from fog and dew. According to Mr. Hubbard, dew cannot be received by a pond unless the temperature of its surface has fallen to the dew-point. Mr. Martin's view is stated in the following paragraph:—

"The effect of radiation of heat from a pond upon the air above it must be regarded, I think, in a different light to the effects of radiation of heat from

the earth's surface, *e.g.*, the down-land. In the latter case, the heat rises with vapour out of the interstices of the soil, and is dissipated into space. The soil being cooled, brings about the cooling of the stratum of air in contact with it. When the cooling reaches the dew-point, the best radiators receive a deposit of dew. But as regards radiation from the surface of the pond, we have seen that the surface temperature is such that it can seldom have effect in cooling the air above it, since the air is already at a lower temperature. The cooling of the air must have been due to other causes, and I doubt if equilibrium between the two is ever obtained. Take one of the cases mentioned. At 9.50 p.m. the water was, everywhere in the pool, at 61°. The air immediately above it was 56°. The water was, no doubt, losing heat, but the air was losing it more rapidly, and the temperature of the air would easily fall below dew-point some hours before that of the water did the same. In that case, the point of saturation being reached, the stratum of air must give out some of its moisture, and this would be rapidly assimilated into the pond. If evaporation of the pond were proceeding at the same time, this would tend to cause the point of saturation of the air to be reached the earlier. So I am inclined to think that dew may be received by a pond on its surface even while the pond-water itself has not yet fallen to dew-point. On the other hand, if it can only receive dew by chilling, as it is often said to do, the air above it, I cannot see how pond-water can ever reach a temperature at night time lower than in the air above it, which would be necessary, if there is anything in this alleged chilling, so long as there is no change in the weather. It could only happen after some hours of freest radiation, and by this time probably the early sun will have begun to warm the air, the effect of this being to increase the amount of vapour which the atmosphere could hold without being saturated, and hence removing all possibility of precipitation."

The point deserves to be further investigated, for it possesses not only a scientific interest, but, in view of the possibility suggested by Mr. Hubbard of employing dew-ponds to supply water in certain lands which at present are waterless, a very practical one also.

FORTHCOMING INTERNATIONAL EXHIBITIONS.

Some interesting information with reference to forthcoming international exhibitions in various parts of the world has recently been given by the representatives of the United States Government in the countries concerned. To commence with the exhibition to be held in Brussels in 1910, it is reported that more foreign participation has been secured than for any former Belgian exhibition. The exhibition grounds are situated on the south-eastern end of the Bois de la Cambre, a short distance from the centre of the city of Brussels. The grounds occupy nearly two hundred acres, and are directly reached by a new extension of the Avenue Louise. Space has been secured by Belgium, the United Kingdom, Germany, Italy, Netherlands, Canada, China, Denmark, Spain, Portugal, Guatemala, Turkey, Uruguay, and Persia. The last Belgian international exhibition, held at Liège, granted space to exhibitors amounting to over one million square feet. In Berlin an international exhibition will be held in 1911, beginning on March 18th and closing on May 15th. The exhibits will represent means of traffic and travel by land and sea, the equipment of conveyances and lodging places for the convenience of the travelling public. The authorities permit any city to install an exhibit demonstrating the methods of lodging, instructing, and entertaining foreign visitors. One of the aims of the exhibition management will be to attract the attention of foreigners to the various places of interest in Germany. The scope of the exhibition is indicated by the following divisions under which exhibits will be grouped:—(1) Railways, sleeping-cars, special trains, dining-cars, steamships, and equipments; (2) tourist agencies; (3) societies for the improvement of travel, tourist clubs; (4) summer resorts, baths, and places of recreation; (5) lodgings and maintenance; (6) guides and tourist literature; (7) industries connected with travel, including cars, boats, airships, bicycles, and saddlery; (8) travelling equipments, comprising utensils, luggage, travelling apparel, outfits, photographic, optical, and similar apparatus; (9) expeditions and discoveries; (10) cinematographic reproductions and lectures. In Norway, an exhibition will be held at Bergen from June 1st to September 15th, 1910. This exhibition will be devoted to tourist and domestic industry exhibits. Foreign firms who make a business of furnishing hotels, foreign steamship companies interested in Norway's tourist traffic, and firms dealing in sporting goods, may, under certain conditions, exhibit goods through local representatives. In Mexico there is to be a celebration in 1910 of the centenary of the country's independence. The people as a whole, are even now, it is said, taking an interest in the coming celebration. In Matamoros, for example, collecting boxes are placed in various public places for receiving voluntary contributions. One or two entertainments have also been given to raise money for the same purpose. As far as can be learnt, the actual celebration will take place on September 14th, 15th, and 16th, 1910. Some of the larger cities will probably have two or three weeks devoted to the "fiestas," but on this matter each town will probably make its own plans. In Panama, much interest is already being taken in the proposed world's fair to be held in the city of Panama in 1915. It is stated that a number of prominent men have consented to be honorary presidents and vice-presidents, and that several meetings have already been held. One of the wealthy landowners of the Republic has given a beautiful site of three hundred acres in the Sabanas.

WOOD-PRESERVING PROCESSES IN GERMANY AND FRANCE.

Various methods of applying preservatives to railroad ties and telegraph poles have been in practical use in Europe for more than twenty years. It would be difficult to find in any advanced European State a single railway, telegraph, or telephone line the ties and poles of which have not been impregnated with an antiseptic composition. Figures are published relating to twenty German telegraphic lines, the impregnated poles of which were set at various intervals from 1877 to 1893. Of those set in 1877 about 35 per cent. were still sound and in use after twenty-six years service, and of those set from 1891 to 1893 there are records of five lines upon which all the poles are still standing. The American Consul-General at Hamburg says that the Bavarian postal service, after thirty years' experience, certifies that the known average life of impregnated poles in Bavaria is seventeen years and a half, and the German Imperial Administration calculated, in 1903, that the known average life of such poles was about sixteen years. In the meantime the work of impregnation is being more perfectly performed, so that future statistics will show better results. In France, the Eastern Railway Company announced, in 1889, that in the twenty-four years preceding 67 per cent. of its untreated oak ties had been replaced, while only 16 per cent. of such as had been treated with creosote had been removed. Beech ties properly impregnated, according to the chief engineer of that railway, have an average life of thirty-five years. More recent conclusions reached in the same system were to the effect that 80 per cent. of creosoted beech ties were good after twenty-seven years of service, while only 54 per cent. of oak ties treated in exactly the same manner were good after twenty-four years of service. The results of impregnation appear so conclusive and undisputed that it would be futile, says the Consul, to present further details on the subject. In recent years the most useful preservative agents in use have been chloride of zinc, creosote, and bichloride of mercury, applied by imbibition, or by impregnation by injection forced by the pressure of the air. This second method of treatment generally consists in placing the wood in closed metallic recipients from which the air is pumped, and the liquid then introduced under high pressure. Until comparatively recently, it was very common to treat wood by injection under pressure of chloride of zinc, diluted with water. While this antiseptic is efficacious, it loses its qualities and becomes hygroscopic. To overcome these disadvantages, creosote was added to the mixture, and under the title of "mixed impregnation" this system has been adopted for the treatment of white wood ties which are too cheap to warrant the use of creosote alone. Hard wood ties, on the other hand, are impregnated with creosote alone, the general effect of which is to close the pores, coagulate the sap, and kill the micro-organisms in the wood. The use of creosote alone is quite unusual in the treatment of telegraph and telephone poles, because of the odour, tendency to melt and run under the sun, and objections raised by the men employed to deal with them. It is common therefore to use bichloride of mercury (the French Government use sulphate of copper), the efficacy of which has been known since the middle ages, when it was used to arrest decay and the action of insects. At the Himmelsbach plant, near Freiburg, this is used in 66 per cent. solution. The wood is plunged into timber or cement receptacles, and there remains from ten to fifteen days. In this plant, moreover, treated poles are given a special coating of some unknown antiseptic, which extends about two feet above, and two feet below the point where the pole enters the soil. This application protects the part where the variations in humidity commonly attack the pole. In the Himmelsbach establishment, there are tanks for impregnating forty ties at a time, under pressure; these tanks being about sixty-five feet long, and over six feet in diameter. Their baths for treating telegraph poles are ninety-eight feet in length.

HOME INDUSTRIES.

The Whisky Industry.—The final report of the Royal Commission on Whisky and other potable spirits does nothing to confirm the rather general opinion that most of the spirit sold in public-houses, and the cheaper priced bottles, is deleterious in its rawness, and adulterated. On the contrary the evidence before the Commission "failed to establish that any particular variety of whisky was specially deleterious." Statements were not uncommonly made that raw spirits, and the cheaper variety of spirits consumed, for instance, at fairs, were specially liable to be deleterious, and to cause "some of the more severe symptoms of intoxication," but this evidence generally amounted to little more than a mere statement. As to adulteration, the Commissioners "were unable to obtain evidence pointing to the presence of any known deleterious substances in excessive quantity in these spirits (whiskies which had been obtained by Excise officers at fairs and public-houses in low-class districts in England, Scotland, and Ireland), or that any foreign substances had been added to them." What "excessive quantity" means in this connection is a little obscure, but the general conclusion is plain and reassuring. It is the conclusion arrived at by the Select Committee of 1890-1, who in their report say, "Your Committee arranged with the Inland Revenue that about fifty samples of spirits should be collected from public-houses, shebeens, and fairs, in various parts of the country to ascertain whether adulterations of a pernicious character might be put into them by the retailer before being given out to the customers. It is pleasing to say that not a single case of such adulteration was found. They varied greatly in strength, being from 14 to 30 under proof, but the spirit was normal."

Absence of Adulteration.—The Commissioners were appointed to inquire whether in the general interest of the consumer, and in the interest of the public health, or otherwise, it is desirable to place restrictions in the materials or processes which may be used in the manufacture or preparation in the United Kingdom of whisky; to require declarations to be made as to the materials, processes of manufacture or preparation, or age of any such spirit; to require a minimum period during which such spirit shall be matured in bond; and to extend any requirements of the kind mentioned to any such spirit imported into the United Kingdom. To all these questions the answer of the Commission is in the negative. They find that there is little or nothing to be added to the Report of the Select Committee on British and Foreign Spirits appointed by the House of Commons in 1890, presided over by Sir Lyon Playfair, and quoted above. As to "What is whisky?" the report takes a middle course. It does not altogether agree with the purists that whisky is a very strictly defined thing—spirit produced in a pot still from either malted barley, as in the case of Scotch whisky, or from barley malted or unmalted, with certain additions of other cereals, as in the case of Irish whisky. The quantity of spirit made in Scotland or Ireland from malt alone, or from a mixed mash of unmalted grain, has been far in excess of the quantity made from any other description of materials, and in recent years practically no spirit has been distilled at any Scotch or Irish distilleries from any materials other than malt and grain. "The general conclusion," say the Commissioners, "therefore, on this part of our inquiry is that 'whisky' is a spirit obtained by distillation from a mash of cereal grains saccharified by the diastase of malt; that 'Scotch whisky' is whisky, as above defined, distilled in Scotland; and that 'Irish whisky' is whisky, as above defined, distilled in Ireland."

Shop Assistants.—The Shops Bill introduced by the Home Secretary last week will not be passed this Session, and is not likely to pass without substantial amendment. The Bill has been introduced, as the Home Secretary explained, with the object of promoting discussion in the country, "and to obtain, if possible, something like unanimous support for its principles." The evils the Bill is intended to grapple with are admitted, but in the attempt to remedy them on the lines of the present Bill it may be found that the "small man" would suffer grievously. The basis of the Bill is that a shop assistant shall not, save as provided by this Act, be employed about the business of a shop for more than sixty hours (exclusive of meal times) in any week. The limitation of hours would not affect the larger shops to any appreciable extent, but it would be otherwise with the small man. The hours of laundry workers, for instance, are very long, and more than cover the whole time during which shops would be open if the Bill becomes law. Now they go to the little shops, but those under the Bill would be closed as well as the large ones. While an assistant's working week might be limited to sixty hours, it would be difficult to debar a man who, perhaps with the assistance of his wife, is conducting a small business, from the opportunity of making a little more money by hard work. There would be difficulty too with those shops in which branch post offices are conducted. Under the Bill shops would for the purpose of the transaction of post office business be exempted from the provisions of the Act to such extent as the Postmaster-General might certify for the purpose. It will seem to many a little incongruous for the law to insist that the needs of the people in respect of the purchase of food can be met by shops closing early, while for the sale of postage-stamps shops have to remain open until later hours. It is sought to meet the difficulty as to the Jews by giving the Secretary of State power by order to declare any area specified in the order to be an area inhabited largely by Jews, and in any such area it shall not be obligatory to close a shop before two o'clock in the afternoon on Sunday if the shop is closed for serving customers from sunset on Friday to sunset on Saturday.

The Thames Steamboat Service. — Now that another attempt is being made to run a Thames steamboat service, it may be interesting to note the history of successive attempts to supply and maintain a Thames passenger service. The first venture of the kind was undertaken by the City Steamboat Company, which was registered in 1845. It commenced with eight boats, and paid an average dividend of 10 per cent. for thirty years, giving a bonus of one £10 share for every two shares held. In 1875 it was merged into the London Steamboat Company, and at the time of its disappearance as a separate organisation it possessed 17 steamers built out of profits. The London Steamboat Company amalgamated, in addition to the City Steamboat Company, the London, Westminster, and Vauxhall Steamboat Company the Sun Steamboat Company, the Westminster Steam Packet Company, and the Waterman's Steam Packet Company. It started with a capital of over £400,000, and its gross earnings for 1876-77-78 were £115,000, £117,000, and £118,000 respectively. Then came the disaster to the *Princess Alice*, and the steamboat service of the Thames has never recovered it. The Thames and Channel Passenger Company took over the business of the London Steamboat Company and undertook to pay 10 per cent. on its first and 7 per cent. on its second mortgage debentures, and to build a new vessel each year. It failed; the gross receipts for 1879 being only £72,000. The Thames and Channel Steamship Company was formed to take over its assets, but only lasted a few months. The River Thames Steamboat Company then took over the boats, ran them for two years, and went into liquidation. In 1888 the Victoria Steamboat Company was formed, to be soon followed by the River

Thames Steamboat Company, which was equally unsuccessful. The County Council's experiment has ust ended in the disposal of the last of its boats at a rubbish price, fourteen having been recently sold for £5,500.

A Ring-Spinners' Association.—As mentioned in these Notes some time ago, it is proposed to form a Ring-Spinners' Association for the purpose of keeping up prices, and the preliminary steps are now being taken. It is to be assumed that the promoters of the Association expect to be able to obtain a great majority of the ring-spinners for it would be difficult, if not impossible, to maintain prices with any large number of outside weak sellers. If the Association were unable to obtain their minimum prices they would have to make stock or stop machinery. Spinners will not stock at high prices. A meeting will be held on the 24th August to authorise the Provisional Committee to proceed with the formation of the Association, to submit proposals, and to elect a general committee. But how will minimum prices affect markets where Lancashire has to meet competitors untrammelled by such limitations? In this connection it may be noted that according to the New York "Journal of Commerce" there is "an enormous increase already provided for in the additions to cotton mill spindleage in New England and the South." It is said on the same authority that this year there will be the greatest increase in spindles in any year since the southern industry began, and that a further expansion in new mills is expected in 1910. "Ultimately," says the "Journal of Commerce," "it is expected that this increased spindleage will bring about a keen domestic competition, and will lower the prices of goods, more particularly the fine cottons that will be excluded from importation through the operation of the new law." And this on top of the abnormal expansion in cotton spindles and looms in Lancashire!

GENERAL NOTES.

Memorial Tablets. — The London County Council have affixed to the house on Hampstead-heath known as "North End-place," and previously as "Wildwoods," a tablet bearing the inscription: "William Pitt, Earl of Chatham, 1708-1788, Prime Minister, lived here." There seems but little doubt that this is the house where Pitt resided for some time in 1766 and 1767 when he suffered so terribly from suppressed gout as to be quite unable to attend to affairs of State. A pathetic picture of the great Prime Minister is given by Mr. Whately (Mr. Grenville's private secretary) in a letter dated 30th July, 1767: "Lord Chatham's state of health . . . . is certainly the lowest dejection and debility that mind or body can be in. He sits all day leaning on his hands, which he supports on the table; does not permit any person to remain in the room; knocks when he wants anything, and having made his wants known gives a signal without speaking, to the person who answered his call, to retire."

Tablets have also been affixed to No. 1, Moreton-gardens, Kensington, for a short time the residence of Jenny Lind (Madame Goldschmidt), and to No. 28, Herne-hill, where John Ruskin lived from 1823 to 1843.

Prizes Offered by the Society of Dyers and Colourists.—The Council of the Society offer the following prizes for the solution of technical problems:—(1.) The Silver or Bronze Medal of the Society and £20 for a full investigation of the mordanting properties of various tanning materials, more especially—(*a*) As to the relative affinity for cotton of the tannins of galls, myrabolams, sumach, divi-divi, &c.; (*b*) as to the relative fastness of the colour lakes produced with these tannins and basic colours, in conjunction with antimony, tin, and iron; (*c*) as to the best method of determining by volumetric analysis, or other means, their relative mordanting power. (2.) The Silver or Bronze Medal of the Society for the best critical essay (not exceeding 10,000 words) on the treatment of effluents from dye-houses and textile factories. (3.) A prize of £20 for a determination of the average degree of diminution in strength of three-standard cotton yarns, *e.g.*, 2/40's American, 1/50's Egyptian, 2/120's South Sea Island, brought about by different bleaching processes. (4.) A prize of £20 for a full investigation of the average degree of tendering brought about in cotton yarn by—(*a*) cross dyeing in acid colours; and (*b*) dyeing aniline black; with the object of fixing standards for the trade. (5.) A prize of £30 for a practical method of causing kemps, when present in yarn or piece goods, to take dyestuffs equally with the accompanying wool. (6.) A prize of £20 for a practical method of dyeing full shades of basic colours on cotton fast to rubbing. (7.) The Silver or Bronze Medal of the Society and £20 for a full investigation of the influence of the various substances present in natural indigo in respect to their influence upon the dyeing of wool by the fermentation vat, and the depth, bloom, and fastness of the shade obtained. All papers, &c., sent in for competition must be delivered free, on or before December 31st, 1909, to the Honorary Secretary of the Society, Mr. Ernest T. Holdsworth, Pearl Assurance-buildings, Market-street, Bradford, from whom further particulars may be obtained. The Worshipful Company of Dyers also offer a Gold Medal to be awarded by the Council of the Society. The medal will be known as "The Dyers Company's Research Medal," and will be given for "the best scientific or technical investigation connected with the tinctorial arts" submitted to the Society for publication before the 31st December, 1909.

PROCEEDINGS OF THE SOCIETY

CANTOR LECTURES.

MODERN METHODS OF ARTIFICIAL ILLUMINATION.

By Leon Gaster, A.M.I.E.E.
(Editor of the *Illuminating Engineer.*)

PART IV.*

Introduction.

In my two first lectures I have dealt with gas and electric lighting. I now propose to deal with systems of lighting which, naturally, lack some of the advantages associated with these highly-developed methods, but yet have themselves certain advantages, and notably those of portability, of being self-contained, and to some extent independent of the supply of fuel from without.

Both candles and oil lamps are of very ancient origin. Dr. Böhm (*Illuminating Engineer*, February, 1908) remarks that oil lamps of a kind were met with in the most ancient Roman illustrations, while splinters of resinous pine were used even in the age of Homer. Candles apparently were of Phœnician origin, and the Emperor Constantine is said to have illuminated Byzantium by candles on Christmas-eve in the fourth century. It is remarkable to reflect how comparatively stationary the manufacture of candles seems to have been until the last century, when the production of stearine and the ingenious invention of a wick that did not require snuffing made the candle a more practical article; it is, however, still worthy of remark that one of the witnesses (a member of a prominent firm engaged in the candle-making industry) examined before the Commission on the standard candle of this country so late as 1881, confessed that he had never contemplated any tests of illuminating power. The treatment of the wick, the quality of wax, and other details, were the subject of very careful attention, but it hardly seems to have been adequately realised that the main business of a candle was to give light.

Dishes of liquid oil and fat were employed even by the most ancient nations; we find that they were used mainly for purposes of ornament rather than for the purpose of providing actual illumination. Indeed, this use of the oil lamp prevails in many churches at the present day. I may mention as an illustration the lighting of Santa Sophia, a church in Constantinople, which Mr. J. B. Fulton recently described in an article in the *Illuminating Engineer*.

Candles, too, are still very frequently employed for decorative purposes, and for the religious and other associations connected with them, sometimes forming an essential part of the ceremonial.

In this connection I may refer to a remarkable book recently published in Vienna by von Benesch, in which an extremely interesting collection of ancient illuminating apparatus, including many tasteful designs of candle holders, oil lamps, &c., dating from the Middle Ages to the nineteenth century, is described and illustrated.

Oil Lamps.

The discovery of oil in America about 1860 led to the development of the petroleum lamp proper. Yet the early lamps were not vastly better than those that preceded them. For

* The Course consisted of four lectures, delivered on February 15th and 22nd, and March 1st and 8th. In re-arranging the material for publication in the *Journal*, the lecturer has preferred to divide it into six parts.

instance, it was not at once that wicks were devised capable of drawing up the oil from below in a satisfactory manner, and therefore lamps were provided with a reservoir placed at a higher level than the flame, thus allowing

FIG. 41.

ILLUMINATION OF CHURCH OF ST. SOPHIA BY SMALL OIL-LAMPS.

the oil to be fed by gravity. The invention of the chimney by Argand, and the draught so produced, was again a great improvement, and the substitution of a ring-shaped wick for the flat variety previously used was also an advance. Oil lamps, however, formed the standard method of illuminating streets before gas was available.

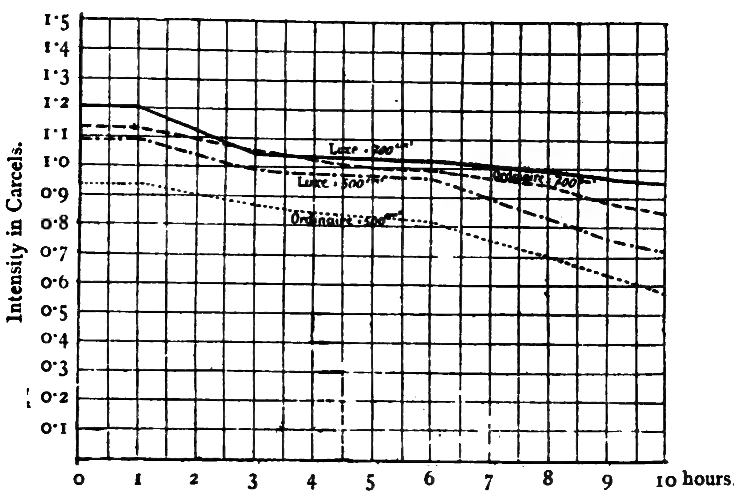
The ordinary petroleum lamp is often unjustifiably condemned for certain defects which are not inherent in it, and can be avoided by suitable design. In country districts the lamps are so widely used that there is still room for the careful study of the best methods of producing and utilising the light produced from oil even

at the present day. This matter formed the subject of discussion at the International Petroleum Congress held at Bucharest in 1907, when papers were presented by M. Aug. Pihan, Herr Proessdorf, and myself. A resolution was moved after my paper asking that the Congress should study and decide upon a type of domestic lamp fulfilling the conditions of the greatest safety and highest efficiency; and this suggestion was formally adopted.

This question of safety is indeed a very vital one to the success of oil lamps, and previous Government, last year, I believe, introduced legislation specifying the exact conditions to be fulfilled by oil used for illuminating purposes in that country. Naturally, such a specification can only be applied to the Roumanian type of oil, and might not answer if used in connection with the Russian or American variety.

M. Pihan, on this and other occasions, has presented details as to the correct method of testing oil lamps, and the paper by Herr Proessdorff, in which 150 lamps were examined, is a useful record of the research on lamps

FIG. 42.



CURVES ILLUSTRATING IMPROVEMENT IN LIGHT OBTAINED FROM OIL-LAMPS BY KEEPING LEVEL OF PETROLEUM IN RESERVOIR HIGH.

to the Congress many prizes had been offered for a lamp which would satisfy the required conditions, but without one being discovered which was considered worthy of the prize.

It may also be pointed out that the design of any particular lamp must take into account the nature of the petroleum which is intended to be used with it. For instance, a lamp intended for American oil would not serve equally well for use with the Russian variety, nor, probably, would the type of chimney favouring the best conditions of combustion be the same in the two cases. The result of trying to burn a variety of petroleum different from that for which the lamp is designed, will probably only lead to the production of incomplete combustion, a smoky flame, and a smell.

Recognising this fact, the Roumanian burning petroleum of different kinds that has recently been carried out.

Another very interesting point was touched upon by M. Guiselin (*Illuminating Engineer*, Vol. I., March, 1908), who demonstrated how greatly the light from an oil lamp was affected by the quantity of oil in the reservoir. An increase of 20 per cent. in the illuminating efficiency can be secured by keeping 700 cubic centimetres of petroleum in the reservoir, instead of 500. This can be easily understood when we remember the need to facilitate the capillary action of the wick. Consumers are, therefore, recommended to keep their lamps well filled up.

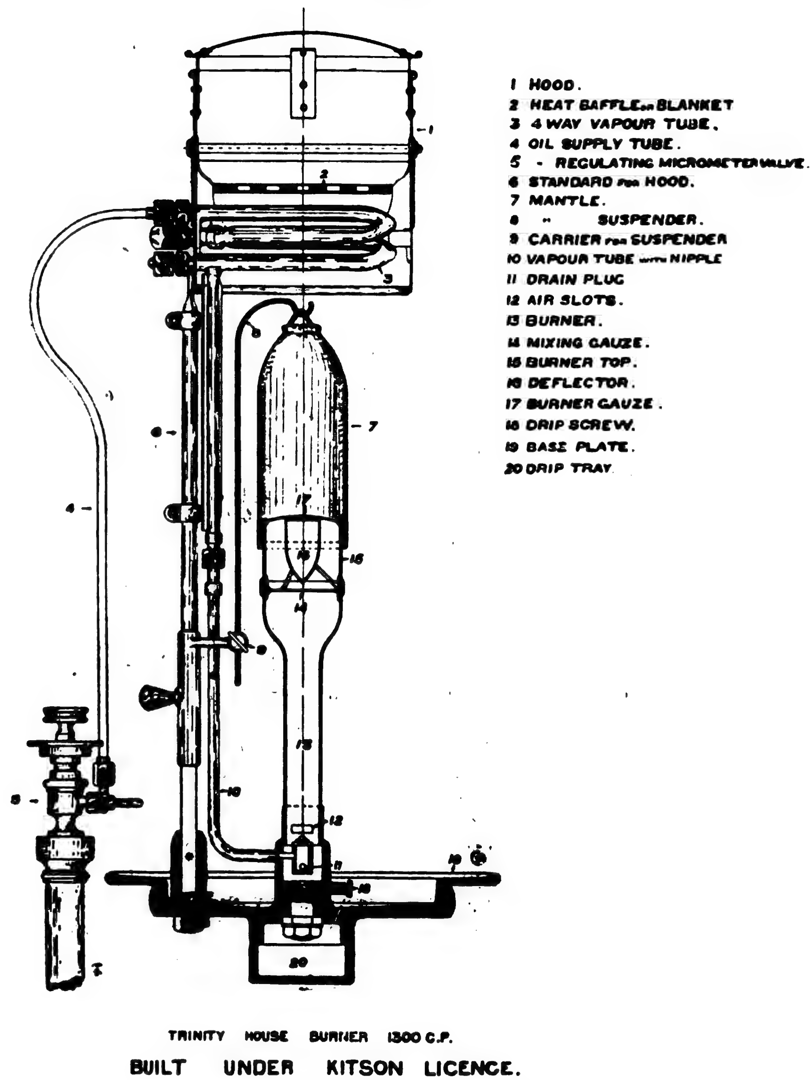
Some very complete researches on the oil lamp as a standard, were communicated by Dr. A. H. Elliott at the second annual Convention of the Illuminating Engineering Society

last year, and in the discussion the importance of careful attention to the wick was dwelt upon. One of the speakers referred to a new non-combustible asbestos type. I have the privilege of showing you to-night a new type of non-combustible wick, due to Dr. B. Monasch, and composed chiefly of carborundum. This same authority has recently contributed a study of the ordinary kitchen oil lamp, and has pointed out that the reflector commonly provided with these lamps is of faulty design.

Incandescent Oil Lighting.

The coming of the incandescent burner suggested a new method of utilising liquid fuels. It had been realised that if a liquid illuminant could be vapourised and mixed with the correct proportions of air, it might be utilised to heat an incandescent mantle, to even greater brightness than is obtained by gas of the ordinary variety, according to the calorific power of the vapour generated. One of the earliest methods of utilising petroleum in this way was the Kitson system, according

Fig. 43.



Sectional Block of Kitson Burner.

FIG. 44.

FORMS OF INCANDESCENT OIL LIGHTS. (THE EMPIRE LIGHT.)

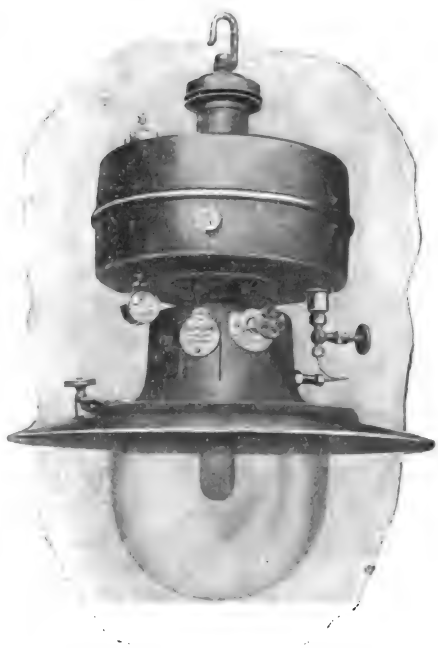
to which the petroleum was compressed at about 50 lbs. to the square inch in a suitable vessel, and then forced through a soft brass

FIG. 45.

BLANCHARD PORTABLE TABLE LAMP.

tube of very small bore into a heating vessel, and subsequently through a needle orifice to a suitably-designed Bunsen burner. This system has found a considerable field for lighthouse illumination, and especially in isolated positions for which a self-contained portable method of generation is desirable.

FIG 46.



BLANCHARD, LAMP HIGH CANDLE-POWER, COMMERCIAL FORM.

The most recent example of the Kitson system, the Empire Light, sold in England by the United Kingdom Lighting Trust, is an entirely portable, self-contained lamp, in which an improvement is introduced by

arranging the heating vessel in a vertical position quite close to the burner instead of above it.

The Blanchard system again utilises a self-contained lamp equipped with an inverted mantle, a special feature being the existence of a second vapourising chamber in which the heavier fractions of the oil can fall and be vapourised by their close connection with the mantle itself. It is claimed that one gallon of low quality paraffin oil in connection with the mantle used in this lamp will give an illuminating capacity of 18,000 candle hours. The use of an inverted burner also enables small units

FIG. 47.

THE PETROLITE LAMP.

to be supplied with greater ease, lamps yielding from 75 to 1,200 candle-power being available. An ingenious and interesting device used in this lamp is the method of registering the level of liquid in the vapouriser, which must be entirely closed and so adjusted as to withstand many times the pressure which it is likely to experience. This consists of a magnetic needle on the outside of the vessel, which is controlled by a magnetic float rising and falling with the liquid within. Lamps for outdoor lighting are stated to burn 20 hours without requiring further attention. A convenient portable form of lamp is shown in Fig. 45.

The *Petrolite Lamp*, an example of which I have also on exhibition here to-night, represents another development in this direction. In this lamp the air is sucked through a porous vessel impregnated with suitable hydro-carbons, a draught being provided by the use of a fairly long chimney. One advantage claimed for this lamp is its safety.

The principle and *modus operandi* of the petrolite lamp are essentially as follows:—The container consists of a highly absorbent and incombustible stone. This stone, which is perforated to allow for the passage of air, is placed in the container and filled with petrol, which is immediately absorbed by the stone.

When lighting the lamp, the insertion of a lighted match in the opening of the burner gallery causes immediately a slight draught in the chimney, sufficient to produce a suction in the inner burner tube. The cold air thus drawn into the lamp has to make its way through the perforation of the stone saturated with petrol. During this passage the air is being carburetted with vapour, and this diluted gas, while being drawn up the burner tube, meets on its way with a further supply of cold air from the outside. Both are automatically mixed in the exact proportion to give a very hot Bunsen flame with perfect combustion.

It is therefore suggested that the evaporation of the petrol in the lamp is not produced by heat, but by causing a draught of cold air to pass through the petrolite container. In this way the burner produces a sufficiently hot Bunsen flame for the most brilliant incandescent light, while the temperature of the lamp body is lower than that of the surrounding air, thus eliminating one of the many sources of danger.

As has been shown, the evaporation of the petrol by a draught of cold air is caused by the up-draught of the chimney. As, however, this draught can only act in the upward direction, but never in a sideways or downward direction, it is claimed that the lamp, if overturned, immediately becomes extinguished, and that, therefore, there is no danger of fire even if the whole lamp is smashed to pieces.

Its safety has been attested by the British Fire Prevention Committee, while it has also been approved by the London County Council as an emergency light for theatres and other places of public entertainment

This lamp has been subjected to very ex

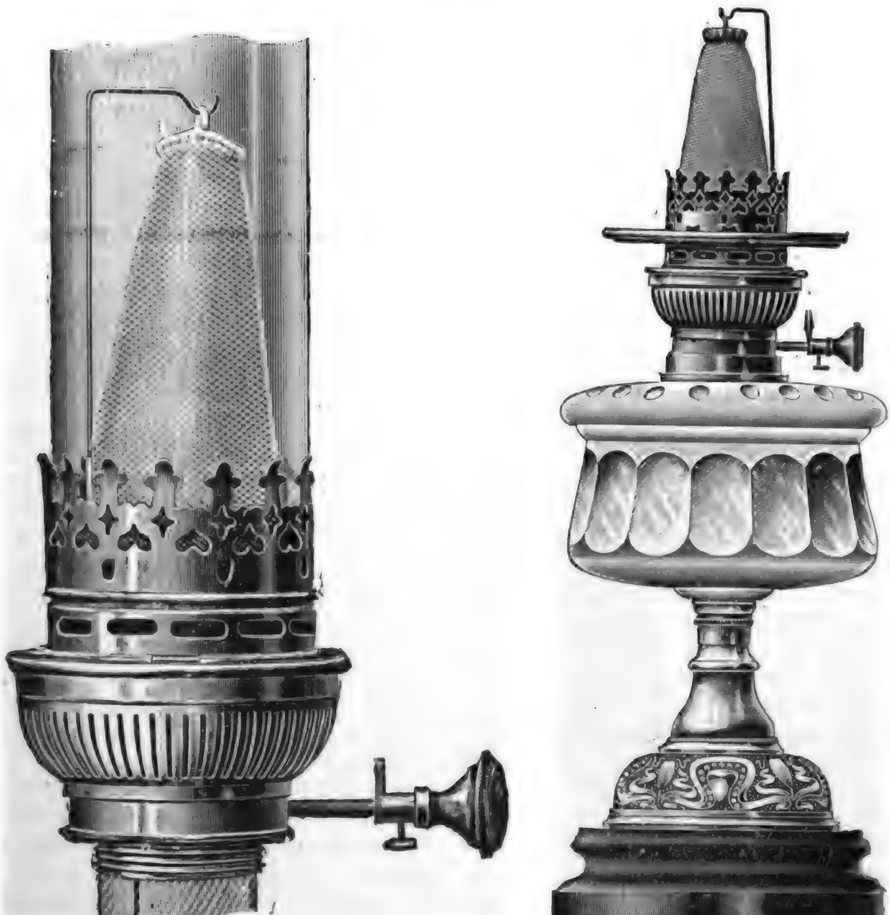
haustive tests by Professor J. T. Morris, who found that it gave a 40 candle-power light for one hour on 1⅛ ozs. of ·695 spirit at 1s. 3d. per gallon. This works out at ⅕d. per hour, or about 5 hours of 40 candle-power light for 1d.

With a double chimney the lamp gave a 58 candle-power light for one hour on 2 ozs. of the same spirit at the same price, showing cost at between ⅓d. and ¼d. per hour; this latter test giving 3·7 hours of 58 candle-power light for 1d.

Yet another form of portable incandescent lamp utilising petroleum is the Lucisca lamp of Messrs. Falk, Stadelmann and Co.

I cannot here dwell on other types of oil lamps, of which there are many more to be found in the market.

FIG. 48.



LUCISCA LAMP. (General View.)

PETROL-AIR GAS LIGHTING.

A considerable amount of interest has been aroused in what are known as "Petrol-Air Systems." They all depend on the generation of a mixture of petrol vapour with air in definite proportions, the air being passed through suitable vessels and carburetted with the illuminating gas. The actual details of the apparatus by which this is achieved vary considerably. Briefly, however, the main essential quality of all is that the mixture generated at the burner should contain a small proportion of petroleum vapour mixed with air, and that the composition of this mixture should be automatically maintained constant. The machine by which this is accomplished usually consists of a small hot-air engine, operated by the gas it pro

duces, together with a suitable blower, carburetter, and gas-holder; in some cases the motive power is supplied by a falling weight, which is newly wound up from time to time, or, where available, water power.

Such machines are designed with a view to being as easily controlled and as automatic as possible; once the engine is started, which should only take a few minutes, the apparatus, it is claimed, ought to continue its functions automatically.

One difficulty against which the system had to contend in the past was the condensation of liquid in the pipes in cold weather. In addition, in defective systems, it was found that, as the burners were turned on and off, and the load on the machine varied, the quality of gas did not remain constant, so that the illuminating value of the lights was reduced, and they tended to smoke, &c., unless readjusted. The best modern systems, however, claim to have completely avoided this difficulty by suitable design of the plant. In this connection I may refer to a discussion on the point which has recently been taking place in the columns of the *Illuminating Engineer* (August, 1909, pp. 549 and 561 to 568), in which several prominent experts connected with petrol-air lighting took part. All contended, however, that these defects were not to be found in the best modern plants.

Naturally in the time at my disposal I can only refer to a few examples which are representative of this method of lighting. By the kindness of the makers, complete working plants of the Aerogen, the Machine Gas Syndicate (Cox's system), and National Air-Gas Company's types are on exhibition. In addition to those exhibited on this occasion, which I now propose to describe, I may mention the De Laitte, Praed, Litz, Mitchellite, and Loco systems, which, however, do not by any means exhaust the types available.

Aerogen Gas (Messrs. Strode and Co.).—Aerogen gas is claimed to be a perfectly uniform mixture, the machine being constructed to keep the percentage of hydrogen vapour per cubic foot of air constant. The petrol-feed and the air compressor work in unison, so that the proportions of petrol and air never vary. The carburation and compression are effected simultaneously in the same chamber, and an even temperature is maintained in the generating chamber by means of the water contained therein.

The petrol is lifted from the petrol chamber and discharged into the carburetting chamber as required, so that there is no possibility of its being flooded by an excess of petrol. A small gasholder is provided which serves as an antifluctuator and maintains a uniform pressure.

The whole mechanism is self-controlled. The machine works quickly when the maximum output is required, and slowly when little gas is used, and stops automatically when no more gas is required. The gas mixture consists of 95 per cent. of atmospheric air and 5 per cent. of petrol vapour, this percentage being maintained automatically by the mechanism under all conditions.

As advantages of the method it is claimed that (1) the gas has a high illuminating power, thus enabling the gas consumption to be small; (2) small sized pipes can be used to convey the gas to the burners; (3) additional air being drawn in by the burners during combustion has a cooling effect on the burner, thus maintaining a longer life for the mantles and burners than can be obtained with gas of a poorer quality; and (4) owing to the small amount of gas consumed the consumption at the burners is silent.

With the motor-driven apparatus a specially constructed gas-meter is provided through which the gas passes. This meter records the amount of gas used and controls the petrol feed. When all lights are turned out the production of gas is regulated to keep the motor running only.

The makers state that aerogen gas can be stored in any quantity, and is not liable to condensation When storage holders are used for country house lighting, an automatic valve is provided so that when the general lights are turned out the holder is fully charged, and the gas supply to the motor automatically turned off, stopping the working of the apparatus, and leaving the storage holder to supply any lights required during the night or in the morning, without the necessity of running the engine.

With the weight-driven machine the light is always available, so that there is no necessity for a storage holder, and economy is effected by dispensing with the motor, thus saving consumption of gas to drive the motor. The weights can be supported from a side wall, or suspended over a disused well, the required drop being from 25 to 30 feet. A steel gantry can be provided to carry the weight where a wall or well cannot be made use of.

It is further stated that the gas can be transmitted for long distances, installations being

in use where the gas is transmitted a distance of over eight miles.

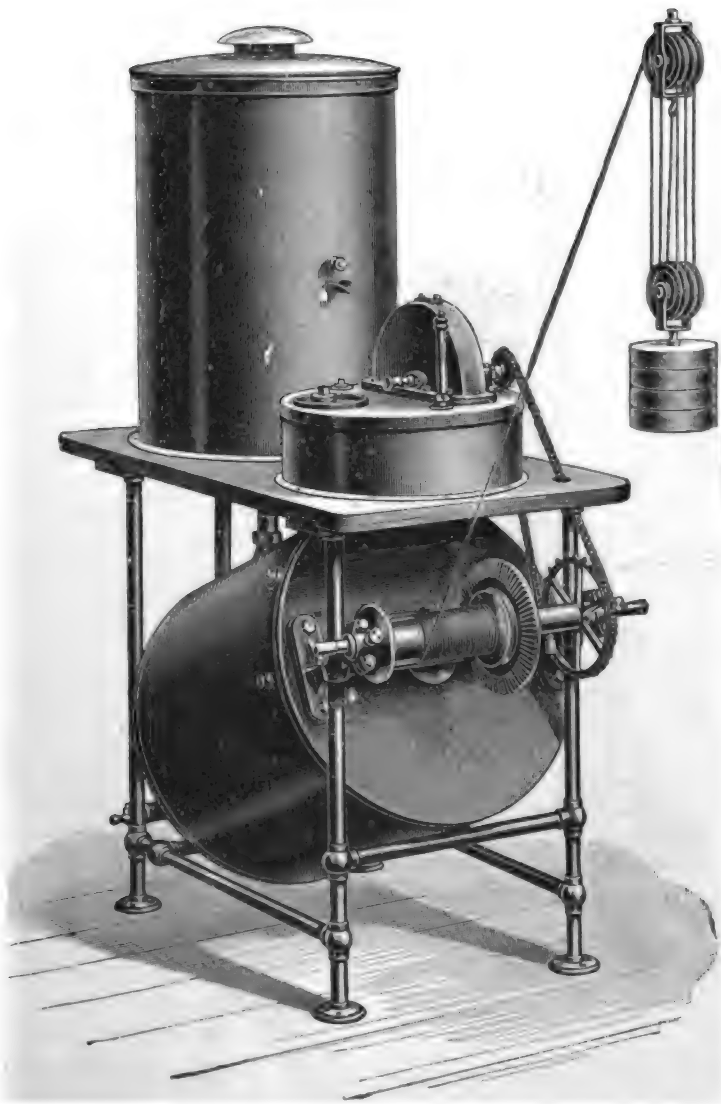
Aerogen gas has a specific weight of 1·2 compared with air. Its odour is not unpleasant, but is distinctly perceptible in cases of escape. One gallon of petrol is said by the makers to produce 520 cubic feet of gas, and three cubic feet of gas, used with an incandescent mantle, to yield an illuminating power of 40 candle-power.

A general view of the weight-driven and water-driven plants will be obtained in Figs. 49 and 50.

Cox's Air Gas System (The Machine Gas Syndicate, Ltd.).—The demonstration given of this method is mainly intended to show the absence of condensation. The main outlet of the machine, Fig. 51 (No. 12 in Fig. 51), is connected on to a coil, which is immersed in ice and salt, and kept at 15° C below zero the whole time during the lecture; nevertheless it will be seen that the light appears to be unaffected. Cocks are fitted in the coil at various bends, and anyone can satisfy himself by opening one of them that no liquid has collected.

The machine, as illustrated in section, may

Fig. 49.



Aerogen Weight-driven Petrol-Air Gas Plant.

be briefly described as follows:—The petrol-container is at the top and numbered 8 and 9, the inner vessel containing the petrol, and the outer one water for sealing the floating bell, 9. The safety of this arrangement is claimed to lie in the fact that there is no possibility of the container bursting, the bell 9 following the displacement of petrol as it is used in the machine. After starting the machine, petrol cock 23 is turned on full and feeds through pipe 22 to valve 21, which is controlled by levers 30 and 20, lever 20 being controlled by the position of holder; the petrol passing valve 21 is conveyed down pipe 28 and drips on to grid 3 which rotates; this grid is so constructed that each drop of petrol is spread into a thin film. When started the hot-air motor drives blower 13; the air is drawn in at the inlet, passed round the jacket of hot air engine, and along casting 1, through the grid in the carburettor. In this process it collects all the vapour and evaporates the films found on the grid, and passes up through pipe 4, through valve 5 into the gas holder. The amount used or drawn from the holder 7 determines the position of this holder, which in turn controls the delivery of petrol and air to the carburettor by means of the connections, 20, 24 and 25. (See Fig. 52.)

This machine is claimed by the makers to be very simple in operation, and within the understanding of almost anyone, care being only required in keeping it clean and lubricating. In addition it is stated that the machines have been found to work quite satisfactorily under very varied climatic conditions.

Fig. 50.

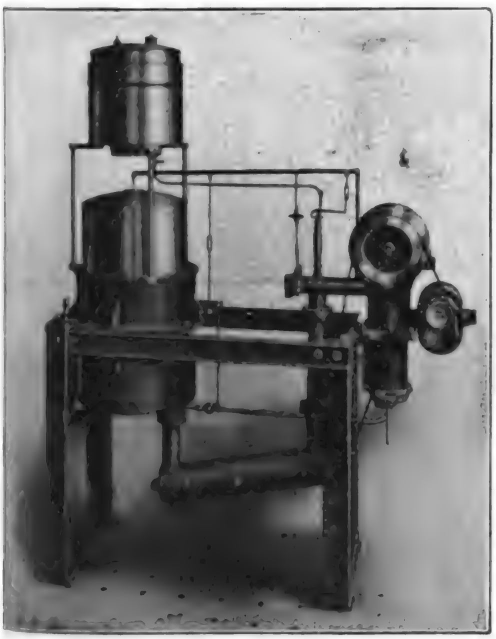
Aerogen Water-driven Petrol-Air Gas Plant.

National Air-Gas System.—An illustration of this method of petrol-air gas lighting is afforded by the apparatus which, by the kindness of the makers, I am privileged to be able to show you this evening. This

method utilises also about 1½ per cent. of petrol vapour, and it is stated that 1,600 cubic feet of gas are produced per gallon of petrol costing 6d. The essential details of the method are connected with the method of obtaining a uniform gas from the carburettor, where the air is charged with petrol vapour. This uniformity must, of course, be maintained, even though the differences in the flow and volume of the air passed through are very great, and there are considerable fluctuations in temperature.

In this method a hot-air engine and air blower are utilised in order to generate the gas, and special arrangements are necessary in order to control the admission of air. This is now accomplished by a thermostatic control, which is arranged to admit automatically spread supplies of carburetted and non-carburetted air. There is also a relief air-valve by which the air is allowed to escape when not actually required for the production of gas. In addition, it is stated that the quality of gasoline used is particularly safe.

FIG. 51.



AUTOMATIC PETROL-AIR PLANT. (Cox's System.)

One result of the small amount of petrol vapour mixed with the air is claimed to be that the products of combustion are less poisonous than in the case of gas, and it is said that the apparatus has even been successfully applied to the lighting of greenhouses, &c.

The general nature of the process by which gas is generated will be understood from Figs. 53 and 54. The apparatus mainly consists of a hot-air engine, an air blower, a vertical cylinder containing the supply of petrol, and a carburettor connected by a series of pipes and valves to a small gas holder, the whole being self-contained and perfectly automatic in working. (See Fig. 54.)

The engine is actuated by a burner, 20, consuming gas produced by the apparatus, and this drives the blower, I. After leaving the blower the air is divided into two streams, the right hand supply passing to the valve, M; the supply on the left flows direct to the carburettor, in its passage through which it is caused to impinge on the surface of the petrol and becomes impregnated with proportionately more or less vapour, according to the amount of gas being used. Thus, if only a small quantity is being consumed, only a small volume of air is passing slowly over the given surface of oil in the carburettor, and becomes impregnated with a large amount of vapour, and therefore requires diluting in the mixing-box, N, to a very considerable extent by air from the air valve, M, in order to bring the proportion of hydrocarbon vapour down to 1½ per cent. of the whole. When a large number of burners are turned on, a large volume of air with a greater speed of flow is passed over the same given surface, and, as the time during which it is in contact with the petrol is far less than when only a small quantity was being used, it necessarily contains less hydrocarbon vapour, so that a proportionate part of the volume of air passing into the mixing-box requires to be cut off in order to keep the mixture uniform. This is done automatically in the following manner:—

The air valve, M, and the gas valve, O, which work in contrary directions, are connected to, and are operated by, the rise and fall of the bell (or upper part) of the gas holder, which is controlled by the main valve, Q. Thus, if more burners are turned on, the holder falls, and proportionately closes the air valve, M, and opens the gas valve, O. When the burners are turned off the reverse action takes place, and thus a uniform gas is obtained under varying demands.

In order to replace the heat lost in vapourising it, and to keep the petrol of a normal specific gravity, the heated water from the cooling jacket of the engine is circulated through a chamber underneath the carburettor, and the heat abstracted (which is

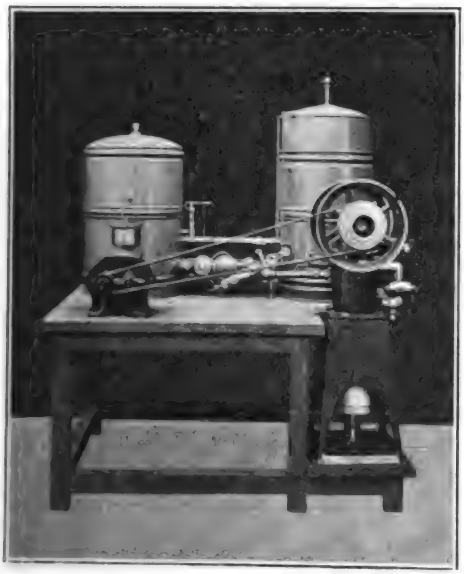
greater or less, according to the quantity of gas being made) is thus replaced. The temperature of the water is controlled by automatically cutting down the supply of gas to the engine burner, this being the source of the heat, according to the number of burners in use. A constant level is maintained in the carburettor, the petrol being supplied automatically as required from the tank, C, by means of the float feed, A.

Petrol-air plants are intended mainly for use in remote country districts, &c., where gas or electricity is not available. However, an interesting development seems to have been recently recorded in Romford, where a number of adjacently situated shop-keepers propose to co-operate and erect a common air-gas generator, anticipating that the result will be cheaper than the local gas supply.

But it is still mainly in districts where electricity and gas are not available that petrol air-gas plants are particularly acceptable, for example, in the lighting of country residences.

Fig. 53.



National Air-Gas Plant. (General View.)

This is a field for which acetylene has also great merits, and there is, therefore, naturally some competition between these two illuminants. A *résumé* of the merits of both methods, may be found in the recent communications to the *Illuminating Engineer*, to which reference has already been made (August, 1909), and also in a paper by Mr. C. Bingham and some correspondence which followed, published in the same journal in the previous year (Vol. I., 1908, p. 547).

One thing may be said with certainty, however. A consumer who contemplates installing a plant of this kind would do well to go to a thoroughly reliable firm, and ensure that he receives the best workmanship available. With a plant of this kind, the daily running of which depends upon his own exertions, success is only attained when the arrangement runs practically automatically and smoothly. The result of poor workmanship or old-fashioned apparatus may be continual trouble and inconvenience to the user. For instance, reference has been made to the fact that, unless this is properly provided against, condensation in the pipes is apt to occur in cold weather, and the householder may find his lights fail on a frosty winter's night.

Most of these systems claim that 1,000 candle-power hour can be produced at a cost in the neighbourhood of one penny or even less; and with petrol at its present price, there can be no doubt of the cheap running costs of such systems.

Naturally, precautions have to be taken as regards the storage of such an inflammable substance as petrol. The fire insurance companies insist upon the actual plant containing the petrol being installed outside the house; it is, therefore, obviously desirable to utilise a form of generator which should be absolutely automatic, and should require attention at not too frequent intervals.

On the other hand, the actual gaseous mixture in the pipes is admitted to be usually of such a composition as to render it almost impossible for an explosion to occur, and the smell of escaping gas, though distinct, is said not to be unpleasant. In the case of such gases as ordinary town gas and acetylene, on the other hand, it is of course admitted that the production of an explosive mixture, owing to an escape, is a possibility, though accidents due to this cause are now certainly very rare.

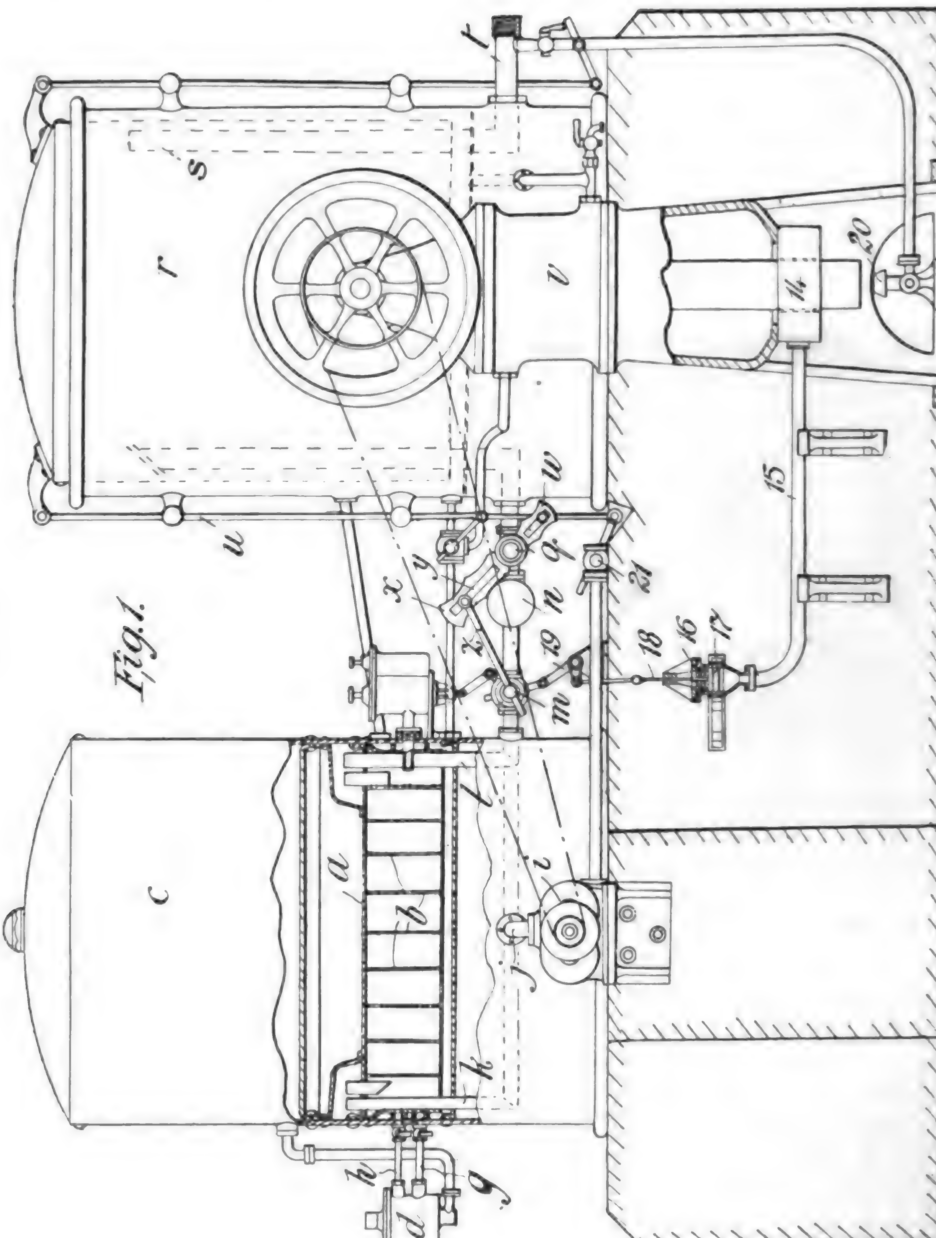
Alcohol and other Self-contained Methods of Incandescent Lighting.

While dealing with self-contained lamps using liquid fuels, some mention should be made of lamps using alcohol. The coming of the incandescent mantle led to the development of a number of lamps of this kind, some using a wick to bring the alcohol to the incandescent burner, and others depending upon a suitable gasifying chamber and a draught.

Fig. 55 shows an illustration of a spirit lamp of the wick type which is taken from an interesting little book on this subject recently published in Germany (W. Brusch, "Die Beleuchtungsarten der Gegenwart"). The support of the incandescent mantle in this case consists of copper, brass, or any good conducting metal. It is arranged to bend round the burner nozzle and partially to encircle the wick tube. In this way a portion of

the heat of the flame can be communicated to the alcohol. The admission of vapour to the burner can be regulated by an adjuster controlling the orifice at the nozzle; it thus passes

FIG. 54.



NATIONAL AIR-GAS PLANT. (Sectional View.)

through the nozzle and is ignited above the gauze in the usual way.

When the lamp is first kindled it is necessary to promote the formation of vapour by preheating. This is done by applying a match at the hole shown in the figure at *b*. Regulation of the admission of air is accomplished by turning the ring *c*.

In the case of lamps intended for outdoor lighting a somewhat different arrangement is necessary, because it is advisable to restrict the apparatus obstructing the light in a downward direction to a minimum. Vapourising arrangements are therefore inserted above the burner. An outdoor lamp of this type, as made by Messrs. Schuchardt and Co., of

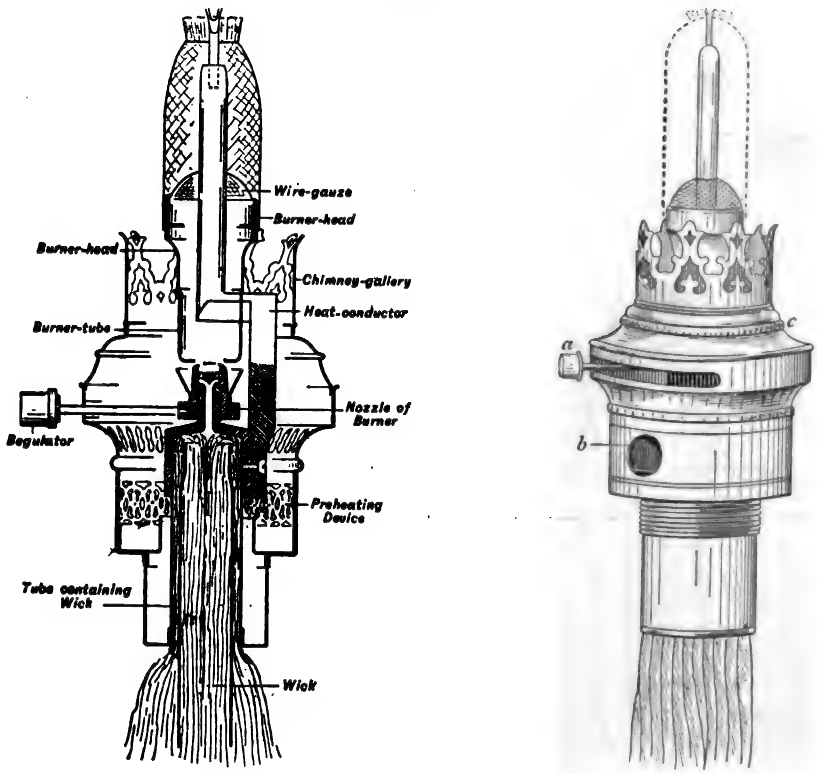
Berlin, is shown in Fig. 56, which is taken from the source previously quoted. The spirit is poured in the vessel through the orifice. When the chain *o* is pulled the cock at *h* is opened, which allows a certain amount of spirit to pass through the tube into the pre-heating chamber *g*; by the second tube *k* the spirit is also allowed to pass into the vapouriser *a*. This consists of a tube filled with asbestos, which promotes a uniform vapourisation of the spirit. The vapouriser is thus heated by the flame at *g*, which is kindled by insertion of a match through the funnel-orifice at *l*.

A pull at the chain *z* cuts off the supply of spirit at *a* and thus extinguishes the flame. It may also be mentioned that the supply of vapour generated is automatically controlled. A strong evolution of gas forces back the liquid in *a*. The intensity of this lamp is stated to be about 75 candle-power, the consumption of spirit per hour being about 140 c.c.

Alcohol has several advantages for use as an incandescent illuminant. Unlike petrol and petroleum, which contain a somewhat uncertain composition of various hydro-carbons of different specific gravity, alcohol has a constant composition, consisting of liquid of the formula C_2H_5OH. This theoretically should make it easier to produce a perfect type of burner, and complete combustion. In addition, while alcohol is admittedly not a very inflammable liquid, and will not easily vapourise, it has also the property of mixing with water, and is, therefore, readily extinguished by a water douche. In many countries, again, there is no natural oil supply, but on the other hand, the agricultural possibilities of the locality make it an easy matter to secure a supply of alcohol for illumination. One difficulty in this respect, of course, is the question of suitable adulteration of the alcohol so as to render it unfit for human consumption. In Russia, in the past, alcohol intended for burning has frequently been purified from the adulterating constituents, and afterwards sold for drinking; the Russian Government, however, offered very high prizes for the discovery of a method of adulteration which could not be nullified in this way.

In passing, a few words may be said about

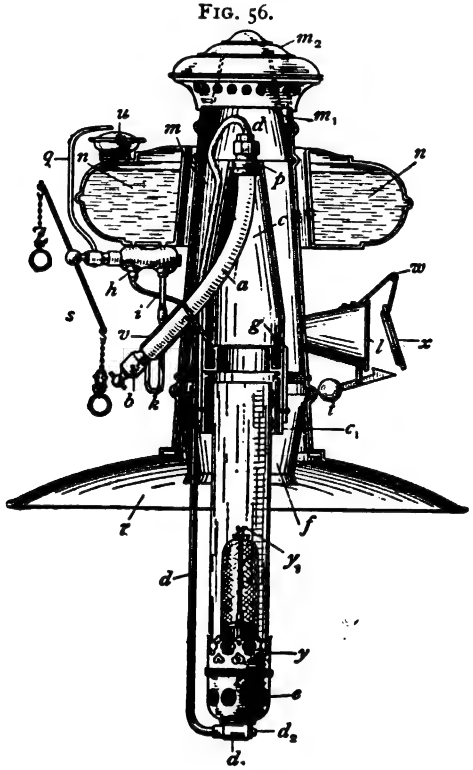
Fig. 55.



Alcohol Incandescent Lamp, with Wick.

the use of various other systems of liquid fuels, which have been found of considerable value for lighting railway carriages, &c., and in other cases where portability is extremely desirable. In these systems various hydrocarbons are frequently liquefied under considerable pressure, stored in cylinders, and may then be carried about at any particular destination. One of the oldest systems in this country is the Pintsch oil gas system in which oil gas is subjected to a pressure of 6 to 7 atmospheres per square inch.

Fig. 56.



Alcohol Incandescent Lamp, with Vapourising Chamber.

The Blaugas again is a special liquid illuminating gas produced by distillation of minerals, such as crude petroleum. The gas is then compressed at the exceptionally high pressure of 100 atmospheres.

Yet another system of a kindred nature is the Wolf gas, which has been described in the *Illuminating Engineer* (Vol. I, 1908, page 681), and a specimen of which, through the kindness of Dr. Achner, is on exhibition to-night. You will be able to form your own conclusions as to the compact nature of the apparatus. This gas consists mainly of such hydro-carbons as ethylene and ethane, and it is claimed to be influenced to an exceptionally small extent by external temperature.

Most of these gases have been rendered much more useful by the coming of the incandescent mantle, for some of them are credited with an exceptionally high calorific value; this leads to a high efficiency in the burner, Wolf gas being credited with about 60 to 70 English candle-power per cubic foot of gas consumed per hour.

Acetylene Lighting.

Introduction.—I must now turn to an illuminant which has made immense strides of recent years, namely, acetylene. For a more complete sketch of this method of lighting, I must refer you to the well-known Cantor lectures of Professor Vivian Lewes on the subject.

Acetylene lighting has only been developed to perfection by dogged perseverance, and many were the difficulties which early workers in the field had to contend against. For instance, acetylene itself seems to be an especially sensitive gas which it was difficult, at one time, to procure in a state of purity, and which tended to form "polymerides," possessing undesirable qualities, such as unpleasant odour, and explosive tendencies.

In addition, impurities such as phosphone rendered the gas liable to spontaneous combustion, and were also said to be responsible for the slight haze which used, at one time, to accompany the burning of acetylene in a room. Again, a mixture of seven of air to one of acetylene is very explosive. Nowadays, however, very careful purification has removed many of these defects, and attention to keeping the generator cool, and other matters, has prevented the tendency to polymerise to a great extent. To-day it is possible to burn acetylene without much smell, and it is said that the gas itself could be rendered absolutely odourless were it not for the danger attaching to such a gas, which would, of course be liable to escape without detection in the event of a leak.

In passing, it is interesting to recall that some of the early work in connection with acetylene was done in this country. Humphry Davy in 1836 studied the subject, and afterwards Berthelot in 1866 took the matter up and showed the complexity of the re-actions taking place in its combustion. Subsequently in 1892 Moissan published the results of some experiments of the manufacture of carbide

with the electric furnace, and experiments were also made by Wilson in the United States and the late Mr. Worth in this country.

Notwithstanding the early work in this country it may be noted that the actual amount of carbide manufactured here is extremely small in comparison with that in most other European countries and in the United States. For instance, according to "The Annuaire International de l'Acétylène" for 1908, the United States heads the list with 35,000 tons per annum, and the other countries follow in the order named, Italy, France, Austria-Hungary, Switzerland, Sweden, Norway and Portugal, Germany, and, lastly, Great Britain with only 1,000 tons.

I should also like to draw your attention to the striking example of the co-operation between those interested in different branches of science that the production of acetylene affords. The hydraulic engineer is interested in the water-power which is almost invariably used for carbide manufacture, the chemist and physicist are interested in the problem of its manufacture and combustion, and the illuminating engineer finally is interested in the use of the light obtained. Curiously, too, it is from water that the power to manufacture carbide is obtained, and it is with water that this carbide gives off acetylene gas; the person carrying a tin of carbide in his pocket can be said, in a very literal sense, to be carrying bottled-up natural energy.

Generating Apparatus.—The development of the generators themselves does not fall strictly within the scope of my lecture. It was at one time the subject of discussion whether the carbide should be allowed to fall into water, or whether water should be allowed to drop on to the carbide. At the present day both methods are employed, and there are varieties of apparatus which show a gradual gradation from one type to the other. In the "Annuaire International de l'Acétylène," an interesting compilation of information relating to this method of lighting for 1908, some account is given of the different types of generating apparatus in use in France and other countries. In France and Italy methods depending on the dropping of water on to carbide prevail, while in Switzerland and Holland, on the other hand, the carbide to water system is predominant.

The general nature of a modern automatic generating plant will be understood from Figs. 57 and 58, which illustrate that exhibited this evening by the Standard Acetylene Co. The principal parts of the plant are as follows:—A, the generator; B, the washer; C, the holder and tank; D, the purifier. When the plant is in action water is allowed to flow from the tank, E, through the valve, U, into the generator, A. The acetylene produced then passes through the washer, B, into the bell, at C, thus causing it to rise.

When the holder is about half full, the control tap, U, is automatically turned off and no more gas is generated. As the acetylene is used up, however, the bell will fall and turn the control tap on again, so that once more generation takes place. This automatic action goes on until the charge of carbide is exhausted. Meanwhile the gas used for burning passes out of the holder through the purifier, D, on to the burner.

One feature of this plant is that two distinct generators are provided, as shown. When one generator is worked out it can be cut out of action to receive attention. When recharging the first generator on the left, the second tap, W, would be opened so that the water could pass into the second generator on the right, and the first tap, W, is closed. The cover of the first generator may then be removed, the sludge run off through the cock, G, the generator cleaned out, and a fresh charge inserted. Various drain-pipes, S, S, S, ... are provided to run off any accumulated water.

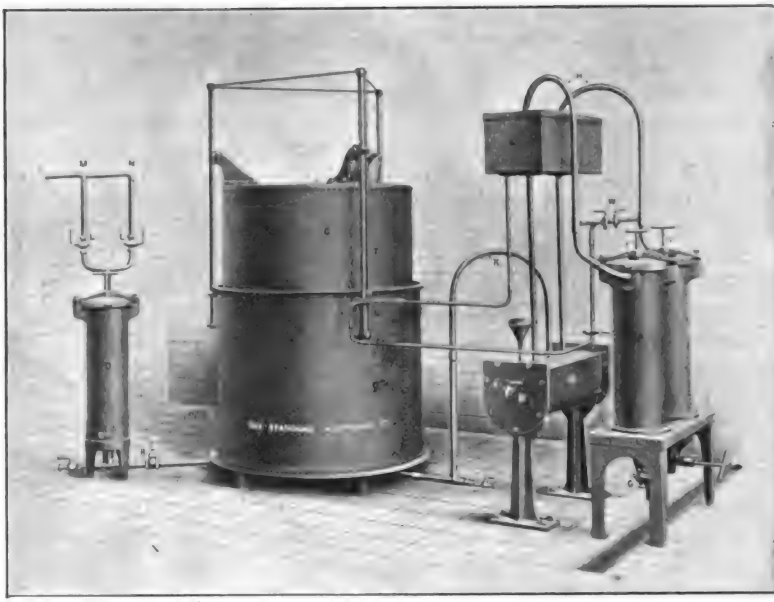
More recently quite a number of ingenious improvements have been introduced, one method, the "Brikettide" system, utilising briquettes composed of granular carbide compressed into cakes with some inactive binding material. For these briquettes it is claimed that they are not hydroscopic and, therefore, do not deteriorate in quality with time and storage, and also that they immediately cease to evolve acetylene when withdrawn from the water. The inconvenient tendency towards "after-gassing," which resulted in the accumulation and ultimate escape of gas when the generator was turned off, was thus claimed to be avoided. Similar efforts in this direction had previously been made. For instance, the carbide was compressed into cakes and coated with paraffin or sugar.

Acetylene Burners.—The design of the acetylene burners has recently been improved to such an extent as to remove many of the early troubles to a great extent and notably in the direction of avoiding their tendency to become choked up. One cause for this habit of early burners was the fact that metal was

used. Nowadays, refractory materials, such as steatite, are used. One notable improvement has been the introduction of a burner in which two flames at an angle play upon one another; the flame temperature and efficiency is increased thereby, and it is also claimed that the tendency to choke is less. The modern acetylene burner probably yields about 30 candle-power per cubic foot of gas per hour.

Another direction in which notable developments in acetylene have been introduced is its application to incandescent mantles. The acetylene flame so produced is extremely hot, and this leads to very efficient results, perhaps as much as 100 candle-power per cubic foot of gas per hour being obtained in special cases; unfortunately, this very high temperature causes mantles to deteriorate somewhat

FIG. 57.



ACETYLENE PLANT (the Standard Acetylene Company), General View.

FIG. 58.

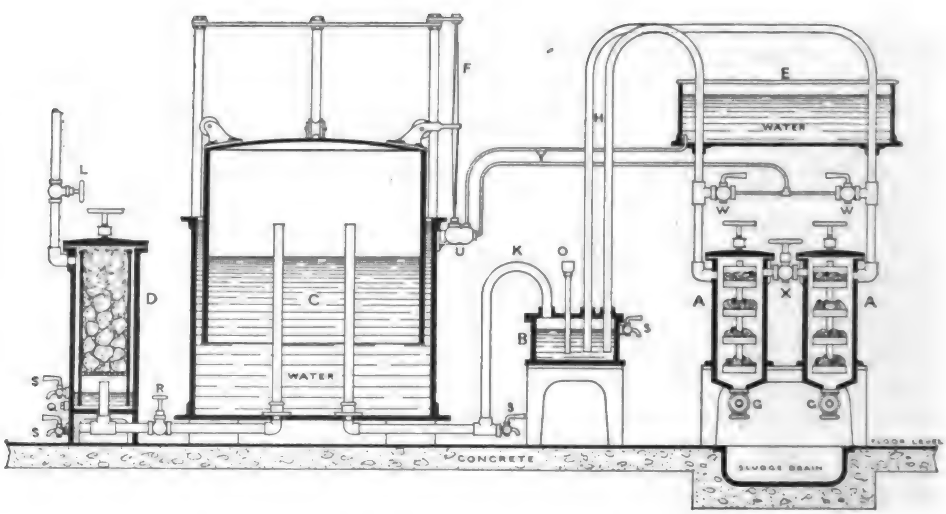


FIG. 59.

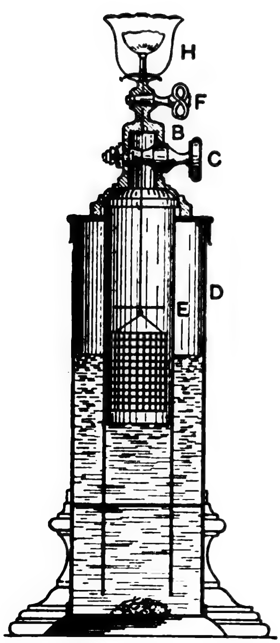
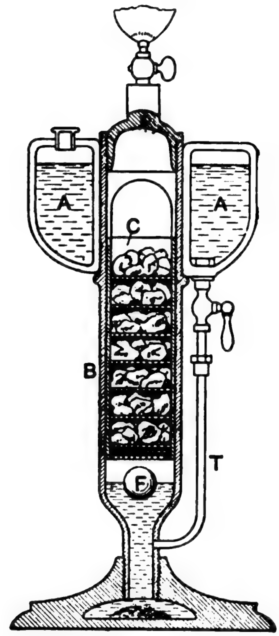
FIG. 60.



TÜRR PORTABLE ACETYLENE LAMP.

rapidly, and it has been found necessary to make them exceptionally small and stout. It has been claimed that the Hella Bushlight, of which we have an example on exhibition, is specially suitable for the acetylene flame, as the refractory needles of which it is composed are able to stand the temperature better; the durable nature of this mantle is also said to render it particularly serviceable for portable lights, for which liquid fuels are, of course, specially intended.

FIG. 61.



CERCKEL PORTABLE ACETYLENE LAMP.

Portable Acetylene Lights. — Portable acetylene lights are of comparatively early origin. The chief difficulties experienced have been connected with the regulation of the pressure and the provision of means of checking surplus evolutions of gas and "after-gasing." Some forms of portable lamps are shown in Figs 59, 60, and 61, which are taken from the before-mentioned "Annuaire Internationale de l'Acétylène." The early Trouvé pattern of lamp (Fig. 59) could not be regarded as practical to-day as there were not adequate methods to check over-production of gas. An improved form lamp due to M. Türr is shown in Fig. 60. It will be seen that by turning the knob at C the vessel containing carbide at E can be raised or lowered in the surrounding water which enters from the outer vessel, D.

The cock, F, merely serves to control the flame at H.

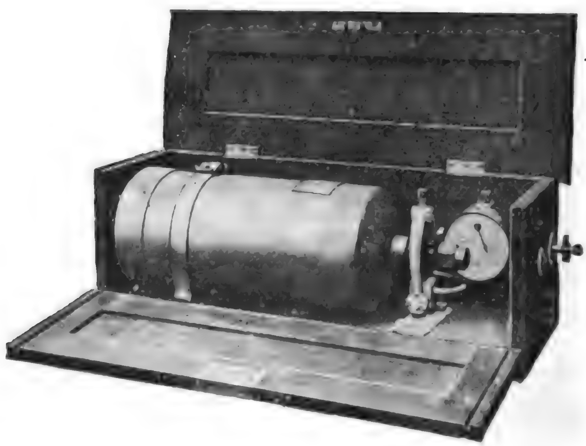
In the Cerckel lamp shown in Fig. 61, again, the water in the reservoir, A, is allowed to fall through the pipe, T, at intervals, so as to flood the carbide within the vessel at B, compartment by compartment. When the level at C is reached, the charge needs renewal.

Many other forms of improved lamps have been introduced equipped with very ingenious devices to control the evolution of gas. Portable lamps have, of course, found a great application for cycles and automobiles; the first lamp of this kind is stated, in the above mentioned periodical, to have been introduced by Mr. Itier, about 1898. They have also been applied with success to the lighting of mines and collieries. One advantage which they are claimed to possess in this connection is that the acetylene flame is stiffer than an oil one, and is therefore not so readily extinguished by a gust of wind. It is also pointed out that an acetylene flame, for a given amount of light, consumes a relatively small amount of oxygen as compared with oil, and therefore does not so readily vitiate the atmosphere in restricted spaces.

Dissolved Acetylene.—I may next refer to what is perhaps one of the most interesting directions in which acetylene has progressed, namely, its preparation in a liquid condition. The convenience of dissolved acetylene was early realised, but there were many initial difficulties to overcome, and not a few serious explosions. Dissolved acetylene, however, can be utilised to-day under a pressure of ten atmospheres if certain directions are observed, including the insertion of some suitable porous substance into the containing vessel. (Fig. 62.)

More recently a much greater development has been achieved through the use of the comparatively cheap liquid acetone, which possesses the remarkable property of dissolving about 240 times its own volume of acetylene at a pressure of 10 atmospheres, and a temperature of 15 degrees. Such a vessel of acetone saturated with acetylene gas at this pressure will, therefore, liberate 215 times its own volume when the pressure is reduced to ordinary atmospheric value. Tubes of one litre capacity, containing about 100 litres of acetylene have been proved to be of very great value where portability is the chief consideration.

FIG. 62.



DISSOLVED ACETYLENE OUTFIT

Special Uses of Acetylene.—It may next be desirable to say a little on the special circumstances under which acetylene lighting is particularly satisfactory. Like the other systems with which we have been dealing, acetylene lighting is essentially a self-contained portable system, and mainly comes into use where electricity and gas are not available. It may indeed be said to fill positions very similar to those for which petrol air-gas is intended, so that the competition between these two systems of illumination is naturally somewhat keen.

In addition, acetylene may be said to represent all stages of portability, from the generator down to the tube filled with liquid acetylene. For instance, in France and Germany it is not uncommon for a small town, or even the

market place in a small town, to invest in an acetylene installation. In country railway stations again acetylene installations have been found to have a great field.

Like petrol-air lighting, acetylene also commends itself for the lighting of country residences. But here, again, the point should be emphasised that it is very essential to secure good workmanship. In the case of acetylene lighting it is particularly desirable that all piping should be properly laid and all joints absolutely gas-tight; consumers may be advised to have work of this kind undertaken by a specialist in acetylene lighting. It is far better to pay a little more and secure a reliable form of plant and sound piping, than to invest in a cheap installation which is a constant source of trouble and annoyance. Many reputable firms are willing to enter into an agreement to execute free any repairs which occur within a given period after installation, thus making themselves responsible for the plant being in good order.

There are, however, many other cases in which dissolved acetylene is particularly serviceable. For instance, when it was necessary to instal a generator on a railway train, the bulk taken up by the apparatus was a considerable disadvantage. More recently, however, liquid acetylene seems to have proved very convenient on quick trains. All that is necessary is to instal the cylinder and connect up to the pipe; at the end of a series of journeys, when the cylinder has been nearly exhausted, it is handed over to be re-charged and replaced by a new one. There are on record many instances of railway trains having maintained their lighting for many hours in an emergency. For instance, a train lighted by dissolved acetylene, which was blocked in a snowdrift in America, was once able to supply light without interruption for twelve days on end, and it is stated that in many of the carriages of the American Lackawanna Railway Company, cylinders only need re-charging every two months. Another field in which liquid acetylene might be expected to play a useful part is for omnibus and tramcar lighting, and I think that the importance and commercial advantage of lighting the inside of these vehicles in a reasonably satisfactory manner, demands the attention of omnibus companies. Again, liquid acetylene has been utilised for emergency lighting on festive occasions in churches.

Naturally acetylene obtained in this way must always be somewhat more expensive than when obtained from a generator, but this is compensated for by the convenience.

The coming of the incandescent mantle, however, has given new life to the application of systems of liquid gas to railway trains. At one time such systems were in danger of being ousted by liquid acetylene, and Professor Vivian Lewes introduced a system by which methane gas was mixed with acetylene, so that a compromise between the cheapness of the one and the high illumination obtainable from the latter was arrived at; this, however, was in the days of flat flame lighting. At the present day the arrival of inverted mantles capable of standing the vibration of trains has given to ordinary gas a powerful weapon, and the use of liquid gas in this way is not to be despised.

At the same time the introduction of the metallic filament lamps, which are particularly suited to the low voltages that can be employed on electrically lighted trains has proved a great help to electric lighting. One very real advantage possessed by such lamps is the fact that their installation would diminish the power output necessary from the generator, for a given illumination, by at least one-third.

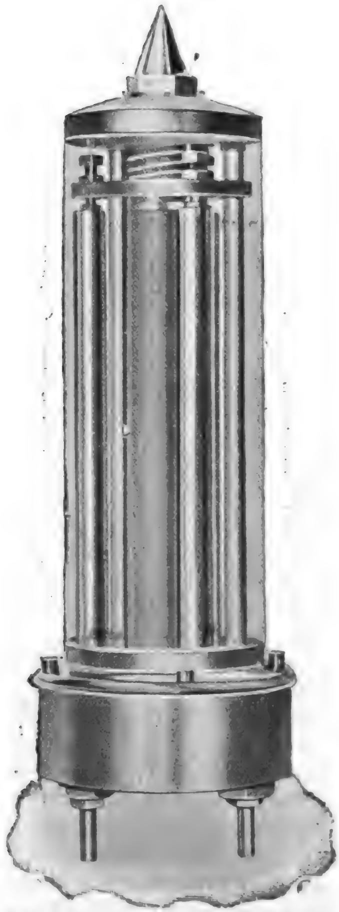
Acetylene Lighting of Buoys, Beacons, &c.—Lastly, I would like to refer to one field in which liquid acetylene has found a very extensive application indeed, namely, the lighting of buoys and beacons, &c., in inaccessible places. Those who are interested in this subject I should like to refer to a recent article in the *Illuminating Engineer* (Vol. I., 1908, p. 905).

Acetylene has been applied to lighthouses, and the lighthouse at Chassiron, one of the earliest to be illuminated by acetylene in France, now utilises an incandescent mantle illuminated by acetylene and credited with 105 candle-power per cubic foot.

But it is for small isolated buoys and beacons that acetylene has been found to be chiefly valuable, for a tube of liquid acetylene can be installed and replaced with great convenience. Canada has found such installations of very great value for buoys on her great rivers, and Sweden, whose maritime system of illumination is exceedingly important, has employed dissolved acetylene very extensively. By the kindness of the Acetylene Illuminating Company, Limited, I am able to show you a most ingenious automatic device for use with buoys of this character. The working of the apparatus is based upon the action of two surfaces, one of which is black and absorbs solar radia-

tion, while the other reflects it. This gives rise to a difference in temperature, and consequently an unequal expansion during the day which causes a valve to close and cut off the supply of acetylene, thereby effecting great economies. During the night, however, when the sun's rays are absent, the valve is open for the same reason that it closes during the daytime, and the apparatus is thus made completely automatic. Similar devices using the property of the selenium cell, the resistance of which is enormously diminished by the action of light, have also been employed.

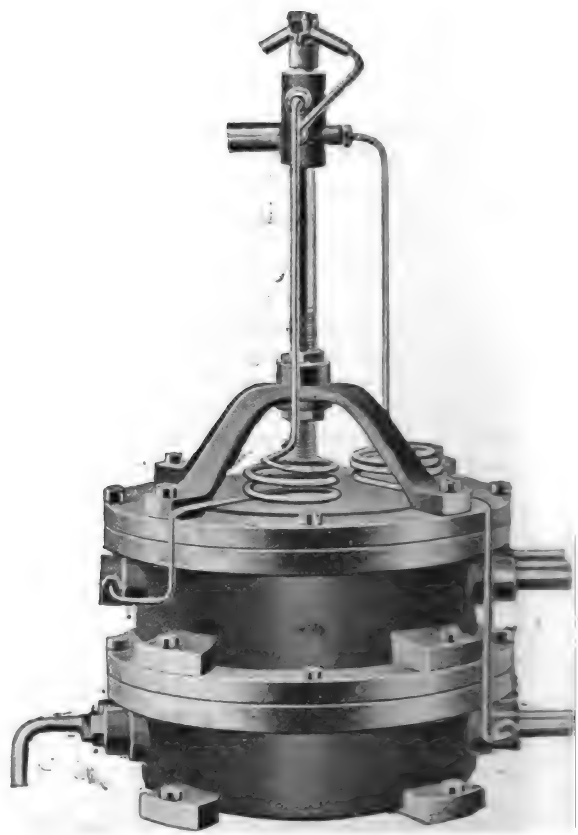
FIG. 63.



DALEN SOLAR VALVE, which automatically cuts off the main supply of Acetylene in Daylight.

Another ingenious automatic device manufactured by the same company—the Dalen apparatus, on exhibition to-night—is arranged to cut off all gas except a bye-pass, and then to re-admit the full flow of gas again at certain regulated intervals. In this way we obtain an automatic flashlight apparatus which is serviceable in two ways. In the first place the flashlight is more serviceable to attract attention in mists, &c., as a fluctuating light is more readily detected than a steady one. In addition it permits a great saving of gas to be accomplished. For instead of burning the light continuously it is now extinguished for certain definite intervals of time and only flashed occasionally. For instance, a flash of a duration of one-third of a second every

FIG. 64.



DALEN ACETYLENE FLASHLIGHT APPARATUS.

third second would lead to a saving of 90 %. The economy in gas over a long period may therefore be very considerable, and the use of this arrangement in conjunction with the solar valve referred to above, has been of great service in enabling buoys so equipped and placed in remote situations to be left unattended for much longer periods of time before a fresh charge of acetylene is needed.

Oxy-acetylene Welding and other Developments.—There are, of course, other important developments of acetylene lighting with which I cannot deal in any detail in

the space at my disposal, and which do not fall so strictly within my province in describing methods of illumination. I may, however, mention the use of the oxy-acetylene blow-pipe, which, in conjunction with a suitable incandescent material, is capable of producing a very powerful light, and is found very serviceable in connection with cinematograph displays, &c. Oxy-acetylene welding, again, is a very important recent development, which has been much assisted by the use of tubes of dissolved acetylene. The convenient simplicity of the apparatus utilising merely tubes of compressed oxygen and dissolved acetylene renders the process specially serviceable when no other source of power is available and in situations in which it is desired to carry the welding outfit from place to place. This, however, is an interesting subject which hardly falls within the scope of my present lecture.

The Costs of Various Illuminants.

Having now briefly described the chief modern systems of illumination, I may, perhaps, be expected to give some account of their relative costs. As I have explained before, I myself do not attach very much value to Tables of this description, partly because of the difficulty in ascertaining the exact conditions under which they were compiled, and also because the results, even if they are obtained on the same basis, will often prove to be misleading if applied to actual practical conditions. I have examined a series of Tables of this kind recently published: in some cases it was impossible to compare them with any precision owing to the different methods used in expressing the results.

I have, however, brought the costs down to the same basis, and compiled the following Table therefrom, which may perhaps be regarded as representative of average conditions :—

Cost of Gas, Oil, or Electric Energy only per 1,000 Candle-power.—Hours (Electricity 4d. per unit; Gas, 2s. 6d. per 1,000 cubic feet; Carbide, 3d. a lb.; Petrol, 1s. 2d. a gallon; Paraffin, 1s. 7d. a gallon).

	s.	d.
Electric flame arc	0	1
High pressure gas	0	1¼
Incandescent high pressure oil	0	1¼
Petrol air gas	0	1½ to 2
Electric mercury vapour lamps	0	2
Self-intensifying gas lamps	0	2¼
Incandescent mantle (low pressure)	0	3
Alcohol incandescent lamps	0	3
Electric open white arc lamps	0	3
Enclosed arc lamps	0	4
Helion electric glow lamps	0	4
Moore tube (electric)	0	4½
Tungsten electric glow lamp	0	5
Osmium electric glow lamp	0	6
Alternating arc lamp	0	6½
Argand gas burner	0	7
Tantalum electric glow lamp	0	7½
Miniature arc lamp	0	7½
Nernst electric glow lamp	0	7½
Metallised electric glow lamp	0	8½
Oil lamp	0	9
Flat-flame gas burner	0	11
Carbon filament electric glow lamp	1	2½

However, I consider that in reality, though such Tables are very useful (provided that the assumptions are clearly stated), as a means of comparing the efficiency of the source itself, they are certainly rarely reliable in any practical case where it is desirable to obtain a given value of *illumination*. For one thing, it is obviously absurd to compare a 1,000 candle-power unit with a small candle-power glow lamp; light for light the high candle-power source may be of a higher efficiency, but then we rarely wish to instal such a source in an interior of moderate dimensions; and in any case the diffusion of light would probably be so unsatisfactory from a single high candle-power source, that we should prefer a number of small sources, even if less efficient. Naturally too, there are very often many other conditions quite apart from cost which come into the problem.

For instance, the method in which the candle-power is specified in the case of different sources may vary considerably. Electrical sources are usually, but not invariably, expressed in terms of mean spherical candle-power, though mean hemi-spherical candle-power, or even horizontal candle-power is often used. In the case of gas lamps, however, it is customary to express the light from the lamp in terms of horizontal component in England, though in Germany the use of mean spherical candle-power is somewhat more usual.

These and many such like considerations do, I believe, usually render general comparisons of costs misleading when applied to practical conditions. When the assumptions made are clearly stated they have a certain value for reference, but any lighting engineer must necessarily consider each case on its merits.

PALO AMARILLO RUBBER.

The Palo Amarillo tree was discovered a few years ago on the slopes of the Sierra Madre, and upon investigation it was found to be a botanically unknown species. It is known in Mexico under a number of common names, such as palo amarillo, palo colorado, papelillo, and cucuracho, the first-mentioned name being generally used. It occurs in the dry semi-tropic zone on the slopes of Sierra Madre, at an elevation of 900 to 4,800 feet, generally being found above the oak zone, and frequently reaching as high as the pine zone of the mountains. It extends southwards from Durango to the southern part of Oaxaca, along the Pacific coast, growing on rather poor, rocky or sandy volcanic soil, and it often forms a part of the xerophytic plant formations that have established themselves on the dry mountain sides. The tree grows to a height of between twenty and thirty-four feet, with a trunk diameter of from seven to twelve inches. In the inner bark of the stem and its branches occur numerous latex-bearing vessels, containing a semi-liquid fluid of milky whiteness, which solidifies on contact with the air. Chemical examination of this latex shows that it contains from 7·3 to 15·7 per cent. of rubber, and from 19 per cent. upwards of resins. The United States Consul at the city of Mexico says that he has personally analysed seventeen latex samples from different parts of the tree, and from trees growing in different soils. The latex from the lower parts of the trunk contains the higher percentage of rubber, as is the case with all rubber-producing trees. The branches carry a latex containing mainly resins, the rubber being about 3 to 6 per cent., and occurring in a form which makes it very difficult to be separated from impurities. The coagulation of the latex is not easy, although it can be accomplished. The resulting rubber is of inferior quality and would commercially be classed with Guayule rubber, which, it is stated, has commanded a price of about one shilling and threepence, where the price of first-class wild Para rubber was three shillings and ninepence, per pound during the last year when rubber prices were low. It may be noted that rubber made according to modern methods from the ordinary Mexican rubber tree—*Castilla elastica*—has reached the highest standard of Para rubber and has realised the same price. The product of the palo amarillo tree being new, the test of time, which after all is the most important one, has not yet been applied, but taking into consideration the low tensile strength, the large percentage of resins, and the rapid deterioration of the latex through enzymes, it is not very likely that palo amarillo rubber will show a better result than the rubber obtained from the guayule shrub. The rubber is easy to vulcanise by the ordinary methods. The exploitation of the latex of palo amarillo is beset with considerable difficulties. The Consul states that he has tapped these trees in all the different manners generally employed in tapping Hevea, Manihot, Castilla, Funtumia, Ficus, or Sapium trees, and he has used over twenty of the different tools and implements, patented and employed in the rubber fields in Brazil, Central America and Africa, and he says that the proper method of tapping palo amarillo is not easy to determine. It is claimed that the palo amarillo tree is very easily propagated. A young branch cut from a growing tree and planted in the ground will grow. Commercially this does not mean much as the exploitable age of a palo amarillo tree must be at least ten or eleven years. A tree of this age does not give a very large amount of latex. The ordinary Mexican rubber tree, *Castilla elastica*, can be exploited when eight years old, and it then gives a larger yield of latex per annum than a ten year old palo amarillo tree. Considering that the latex of the former contains from 25 to 47 per cent. of pure rubber, against about eight per cent. in the palo amarillo latex, it is difficult to see the advantages of the latter under cultivation.

A TELE-VISION INSTRUMENT.

Writing in the August number of *Knowledge*, Dr. Alfred Gradenwitz gives a short but interesting account of an instrument just invented by Mr. Ernest Ruhmer, of Berlin, which is the first actual solution of the problem known by the barbarous compound, tele-vision. Dr. Gradenwitz had an opportunity of inspecting the machine before it was sent to Brussels for demonstration before the promoters of the Universal Exhibition which is to be held there next year, and of which a complete television apparatus, costing the sum of £250,000, will be the principal feature. The demonstration apparatus has been produced at a cost of £250, and owing to its more elementary construction only lends itself to the reproduction of simple patterns, consisting of squares arranged in different combinations. A projection apparatus throws the pattern on a screen hung up on the wall. The screen is a square divided into 25 square sections.

"Behind each of these sections," writes Dr. Gradenwitz, "is arranged a highly sensitive selenium cell in which, by a novel process, inertia has been absolutely eliminated. It thus responds instantaneously to any variation in lighting it is exposed to.

"At the receiving station is arranged a similar screen, divided into the same number of sections, each of which communicates with the corresponding section on the transmitting screen. While the actual system used in transmission is kept secret, this much may be stated, that a highly sensitive mirror galvanometer reconverts the fluctuations of current produced by fluctuations in luminous intensity on the transmitting screen into corresponding light variations. To the right of the receiving screen is seen the accumulator battery, supplying the current to the tele-vision circuits.

"As soon as a perforated pattern is inserted into the projector, a telegraphic reproduction of the picture is seen to appear at the very moment it is thrown on the transmitting screen. The sluggishness of the

cells has been compensated to such a degree that the telegraphic picture will respond practically instantaneously to any motion. In fact, a reproduction obtained at most in a few minutes with the photo-telegraphic apparatus so far constructed is here achieved in a fraction of a second, so that several phases of a motion can be reproduced within a second.

"It is hard to realise what sum of laborious work had to be expended in constructing even this relatively simple apparatus. In fact, each section, with its selenium cell and mirror galvanometer device, is an apparatus of precision in itself, while the definite apparatus will be composed of 10,000 elements of the same kind. Each selenium cell will have to be wound personally by the inventor, who never entrusts his work to anybody else."

WORLD'S TIME INDICATOR.

A UNIVERSAL TIME INDICATOR.

A clock, of entirely new design, and known as the "World's time indicator," has recently been made by Messrs. Kendal and Dent. Its principal object is to show at a glance the time all over the world. It consists of a clock movement, in front of which (in lieu of the customary hands) a disc is mounted which revolves with the earth once in 24 hours, having the hours 1 p.m. till 12 midnight, and 1 a.m. till 12 noon, painted on its outside edge, the hours being divided into intervals of five minutes each. In the same plane as the disc is a fixed plate or dial with a circular aperture to accommodate the disc. The dial has Greenwich painted on the top, the names of the other places being arranged at such distances from Greenwich that at any moment the corresponding time for any part of the world is shown. Greenwich being in the centre, the places which are situated in the east, and, consequently, are fast of Greenwich time, are painted on the right-hand half of the dial, the places west, and slow of Greenwich, being on the left-hand side. The clock can be set by turning the disc either from the front or from the back, so that if it is desired to ascertain the time at any place abroad at a given time in London, or other place, the disc can easily be set to give the information. The corresponding times for all other places will also be indicated on the dial.

The clock is at present on view in the hall of the Society's House where it may be seen by members until Wednesday, September 1st.

BELGIUM IN THE FAR EAST.

In recent years Belgium has displayed decided energy in the direction of the expansion of her already important trade in the Far East, and the relatively conspicuous position she now holds among the European nations, whose rivalry for commercial supremacy in that quarter of the globe is of the keenest, shows that her efforts have not been exerted in vain. The Belgian Government intends to participate in the International Exhibition which is to be held at Tokio, and will, it is asserted, use every endeavour to make Belgium's exhibit one of special prominence. The Government has also decided to install its diplomatic and consular officers in the East in more imposing quarters. A splendid new building for the Belgian Legation at Peking is now nearing completion, arrangements have been made at Shanghai for an imposing consulate-general, while at Tokio a similar building is to be erected. At Seoul, the Corean capital, a new residence has lately been built or the diplomatic representative of Belgium. These undertakings on the part of the Belgian Government

necessitate considerable increases in the annual budget, but such expenditure is looked upon by the commercial community in the country as an excellent investment for the nation. According to the American Consul at Liège, it is only since 1896 that Belgium has made serious efforts to enter the field of commercial activity in China. During that year the Belgian Minister at Peking notified his Government of the possibility of a Belgian firm being awarded the contract for building the Peking-Hankow railway line. The Belgian Minister of Foreign Affairs immediately called together a group of financiers and manufacturers of railway material to look into the question. This meeting resulted in the organisation of the Société d'Etudes de Chemin de Fer en Chine, that at once took the matter in hand. Important orders were given to Belgian firms for railway rolling stock and other material, and this proved to be Belgium's initial move in the expansion of her trade with the Far East. Prior to 1905 the efforts made by Belgians to foster closer commercial relations with China, being largely confined to the action of single individuals or firms acting independently, were not productive of results in keeping with the immense possiblities offered by the Chinese market, and at the same time were far from doing justice to Belgian commercial and industrial activity. The subsequent agitation in the commercial world, brought about by a full realisation of these conditions, led eventually to the organisation in Brussels of the Chinese-Belgian Chamber of Commerce, an institution having for its object, primarily, the grouping together of all interested industries, and assisting in every possible manner in developing and fostering their relations with the East. Supplying manufacturers and commercial bodies with information relative to the important markets of China, pointing out the kind of goods likely to meet with favour, and the prices for which such goods could be readily sold, emphasising the numerous opportunities for developing Oriental trade, encouraging a spirit of initiative on the part of Belgian industrial interests in taking advantage of these opportunities, supplying the Chinese merchants with information that would facilitate the exportation of their products to Belgium, and the purchasing in that country of goods that could find a ready sale in China, are among the leading aims of this Chinese-Belgian Chamber of Commerce, fostered through the intermediary of its official organ, entitled "Chine et Belge." This publication contains much useful information, and is expected to prepare the way for a vast army of Belgian manufacturers and merchants to form new trade relations. Another association, founded on similar lines, for fostering trade relations with Japan, is the Société d'Etudes Belgo-Japonaise. The special pains taken by Japan at the Liège Exhibition, in 1905, to make her section prominent, is considered as indicating a strong desire to enter into more intimate commercial relations with Belgium. The society has sent a representative to Japan. As a basis for his investigations, the society asks its members to indicate the special subjects in which they may be individually interested, so that a complete set of interrogatories may be submitted, such as will be of value in furthering the interests of increased trade with Japan. It is said that the information embodied in the replies to these inquiries will doubtless clearly illustrate a fact perhaps already well known in some quarters, that Belgian products are now extensively sold in Japan, but that, in most cases, such sales are made by other than Belgian houses, and that an extremely small percentage of such products finds its way into Japan by means of direct importation from Belgium. The work of the Société d'Etudes Belgo-Japonaise will include Formosa, Corea, and Manchuria. Owing to the success of the two organisations mentioned, others of similar scope have been recently formed, such as the Société Belgo-Russe, and the Société Belgo-Persane.

ARTS AND CRAFTS.

Design and Craftsmanship.—There is a feeling amongst competent trade designers, old and young, that design is in rather a bad way; that the public (or, at any rate, the middleman who caters for it) has at the present time no particular use for it, and next to no appreciation of what is good; that it feels, for the moment, very little interest in design at all. These men have watched the crafts taking little by little their rightful place among the lesser arts; they have been glad to see them getting their due, and some at least amongst them have helped to get them their due; but now they are beginning to feel as though the process had gone far enough, as though hand-work pure and simple were absorbing rather more than its proper share of public interest. It is not unnatural that, after many years of art teaching which failed to recognise the needs and the possibilities of artistic craftsmanship, the crafts, once come to life again, should want things all their own way; it is not surprising that an uneducated public opinion (and public opinion is not so rapidly educated as some folks seem to imagine) should seize upon the idea of craftsmanship with delight, and run the very word to death. Neither of these things need mean very much. Trade designers, like the rest of the world, look at things too much from their own point of view—and their judgment is not, therefore, to be trusted too implicitly. But, for all that, there are certain facts which have to be faced. Schools of art have in recent years been spending a large proportion of their energies on craft teaching. So far, so good. Craftsmanship is the foundation of applied art and it badly wanted attention. But applied art does not end there, and students have been rushing headlong upon craftsmanship only to find, too often, when their course was ended, that no one wanted their particular kind of craft work and that they could get no work to do. That is, after all, only the natural swing of the pendulum.

Art teaching which took no heed of craftsmanship has been avenged by a craftsmanship which makes little or no demand upon design. That is where the mischief has come in. It is because young people have so often been led to think that design is merely a subsidiary part of craftsmanship that so much modern craft work fails to satisfy those whose knowledge of things artistic is not wholly superficial. It is, perhaps, partly because designing upon paper has come to be spoken of rather scornfully and because the amateurs who flock to schools of art, and who ought to form the backbone of sound public opinion, have come to look upon it as a rather dull and unnecessarry subject, that the common demand for such things as wall-papers, carpets, tiles, printed and woven stuffs—for the things which cannot be produced in schools of art—is so tasteless and uneducated. Signs are by no means wanting that a saner and more reasonable view of the relative claims of design and workmanship is beginning to prevail. Designers may not see it—probably they would not be the first to recognise it—but there does seem to be a tendency both amongst teachers and students to realise more than they have done in the last few years the importance of a systematic study of design. Not until this feeling grows more general will public taste have a chance of improving. We flatter ourselves when we fancy it is always advancing.

National Competition.—If the exhibition of works to which prizes and commendations have been awarded in National Competition provides this year no very fresh or striking features, it proves on further study to be, on the whole, rather more interesting than usual. The greater part of the gold medals are given for book decorations of one kind and another or for figure compositions; but the steel presentation trowel from Leeds, with its leather case and damascened blade, has quite earned its award—and a very large proportion of the silver and bronze medals go to craft work or design. The show, on the whole, goes to prove that after a period of upheaval, things are beginning to settle down, and that in a very promising way. To begin with, a higher level of achievement seems to be demanded generally by the examiners. Of course, the standards of so many different men cannot be exactly the same, but it is much easier this year than it has often been before to guage the probable award made to any design without looking at the label. It seems to have taken the examiners as a body some years to learn to discriminate between the charm that is due to the quality of a material and that due to the invention of the artist, and to award prizes rigorously for design; but they show this year, both by their reports and their awards, that they are quite aware of the danger of being caught by effects which are none of the student's making, and determined to reward the candidate for what he has himself done rather than for merits which belong in great part to a material or a process of execution. It is, of course, rather difficult for an artist, whose natural inclination and training lead him to admire and delight in whatever is beautiful, to judge severely in this way; but it is quite obviously the right one, and the judges are to be congratulated on having arrived at it.

In the work exhibited there seems to be an improvement this year as regards both design and craftsmanship. There is nothing in the way of enamelling, jewellery, embroidery, cut-work, bookbinding, or illumination which commands attention; but there is a fair quantity of very capable work in all these sections and comparatively little of the crude sort of execution which might have passed muster a few years ago.

As regards design, too, the outlook seems very favourable. Not only are the flower studies for use in design very satisfactory, but the exercise known as "plant and three designs," in which the student has to send up the drawing of some plant with three different designs based upon it, is very much better done than usual this year; and that the "designs are this year," as the examiners point out, "more obviously founded upon the plant studies on which they are supposed to be based," is as it should be. There is evidence of far greater taste than heretofore in the colouring and general presentment of much of the illumination. As regards pattern design, too, things seem to be moving, however gently, in the right direction. There is not, so far, very much style about the work. It looks, indeed, as though very often the students were not quite sure what they themselves wanted to get, and had not knowledge enough of historic ornament to help them out of their difficulty, but the cocksureness of ignorance seems to be far less rampant than it was not so very many years ago. In short, the designs this year, if not very remarkable, are more modest, more restrained, more tasteful than they have been for some years past. The students who sent in some of the best work this year seem, if only they are teachable, to stand a chance of going further in the end than some of those who did more striking work two or three years ago.

Design at the Royal College of Art.—The show on the other side of Exhibition-road, of work done at the Royal College of Art is, from the point of view of art and craftsmanship, much less attractive. There are some very dainty little pieces of embroidery, and some interesting work in other crafts, but the exhibition as a whole is disappointing. After inspecting the work done in London in the schools aided by the London County Council and the output of the provincial schools as exhibited at National Competition, it is only natural to expect something rather better from the Royal College. The college stands in relation to schools of art generally, much as a university does to ordinary schools, and a proportion of its students at least consists of national scholars—the pick of the National Competition exhibitors of former years—and yet in looking at the design work and craft work

exhibited at the college, one is inclined to wonder how much of it would have taken a high award at National Competition. The standard is certainly not measurably higher, if we judge by results, than in the best of the London and provincial schools. Of course, it is somewhat of a shock for a provincial student to come up to London and be left to wander amongst the treasures of so great a collection as that housed at the Victoria and Albert Museum. And again, at the college there may not be the same inducement to do work which will look well in exhibition, as there is in schools where so much depends on this kind of success. But, when every allowance has been made, it would seem that the students at South Kensington might and ought to make a considerably better show than they have done.

NOTES ON BOOKS.

Bamboo for Paper-making. By R. W. Sindall, F.C.S. London: Marchant Singer, and Co. 2s.

Although bamboo has been recognised from very early times as a suitable material for hand-made papers, and has been utilised for this purpose for a great many centuries by the Chinese and other nations of the East, it is only in recent years that any serious attempts have been made to investigate the possibility of adapting it to the requirements of the modern paper mill. The first of such attempts was initiated by Mr. Thomas Routledge in 1870–75, and he published the results of his investigations in two pamphlets, "Bamboo considered as a Paper-making Material" and "Bamboo and its Treatment." Since that date a good deal of information has been published from time to time, and the present work is an attempt "to collect and classify the available data and to present the known facts in simple, condensed form, in order that the possibilities of an organised industry may be properly mastered." At a time when the demand for good paper pulp is becoming keener and keener every year, one cannot afford to disregard any material which may assist in averting a threatened famine, and Mr. Sindall's qualifications for his present task are vouched for by the fact that in 1905 the Government of India requested him to visit Burma to investigate the subject on the spot. The result of his enquiry was published in 1906 in a special report, "The Manufacture of Paper and Paper Pulp in Burma." The pamphlet contains interesting information on the growth and cultivation of the bamboo, the supply of material, the price of raw material, experimental plant, mill equipment, &c., which should prove of value to all those engaged in the paper trade. The work is printed on paper made from Burmese bamboo. The firm who converted it into paper regard the experiment as satisfactory in every way. The paper, they say, is strong, and possesses a surface calculated to be most useful for special kinds of printing, especially lithographic work.

The Engineering of Ordnance. By A. Trevor Dawson, Lieut., R.N., M.Inst.C.E., M.I.Mech.E., &c. London: Percival Marshall and Co. 2s. 6d.

The late Gustave Canet was an eminent artillery engineer, and it was fitting that the first Gustave Canet lecture, established in his memory at the Junior Institution of Engineers, should deal with such a subject as the engineering of ordnance. Lieutenant Trevor Dawson deals in an interesting fashion with many aspects of his theme. Beginning with a brief reference to "Mons Meg," the famous fifteenth century gun, which is still fired daily, at 1 p.m., at Edinburgh Castle, he passes on to describe the most up-to-date developments of modern ordnance, and discusses in succession the influence of metallurgy on guns, the influence of powders on the ballistics of guns, the influence of mechanics on ordnance, and, finally, the problem of the flying machine. The value of the lecture is enhanced by 68 plates, which are excellently reproduced.

GENERAL NOTES.

Imperial Arts League.—The Imperial Arts League has just been formed with the object of associating all members of the profession in every branch of the fine and applied arts, together with laymen interested in art matters, for the protection of artists, and for the advancement of the common interests of all concerned in the production, possession, or preservation of works of art. The organisation is officially supported by the Royal Society of British Artists, the Royal Institute of Painters in Water Colours, the Royal Institute of Oil Painters, the Royal British Colonial Society of Artists, the Ridley Art Club, the Society of Women Artists, and the Liverpool Academy of Arts. Among the members are Lord Balcarres, Sir H. von Herkomer, R.A., Sir E. J. Poynter, P.R.A., Mr. T. Brock, R.A., Mr. G. Clausen, R.A., the Hon. John Collier, Mr. Walter Crane, Mr. Frank Dicksee, R.A., and Mr. H. Thornycroft, R.A.

Atmospheric Nitrogen.—A review was recently given in *Stahl und Eisen* of the present position of the various processes for the recovery of nitrogen from the atmosphere. The whole question turns upon the possibility of obtaining the nitrogen by this means in a cheaper form than it can be bought in the natural compounds of this element already on the market. The only requirement for the artificial production is power at the lowest possible rate. The air contains 79 per cent. of nitrogen to 31 of oxygen. An account is also given of the electric processes for the production of calcium cyanamide by the plan proposed by Messrs. Caro and Frank of passing pure nitrogen over highly-heated calcium carbide. The Birkeland and Eyde systems, and those of Schönherr, Haber und Konig, are also discussed.

PROCEEDINGS OF THE SOCIETY

CANTOR LECTURES.

MODERN METHODS OF ARTIFICIAL ILLUMINATION.

By Leon Gaster, A.M.I.E.E.
(Editor of the *Illuminating Engineer.*)

PART V.*

INTRODUCTION.

In the previous lectures a very representative collection of different systems of illumination has been described, which may be said to offer almost a bewildering variety of choice to the consumer. I now wish to collect together some of the threads already taken up, and to say a few words upon the actual utilisation of the light available.

I have referred to the alteration in modern industrial conditions, our tendency to use more and more artificial light, and to continue to turn night into day; we now carry out our work in the night time with a facility undreamed of by our forefathers. At the same time we must feel that this very facility carries with it a degree of responsibility with which our forefathers perhaps were not troubled. At one time, before gas and electricity were available, there was no serious attempt to pursue our ordinary vocations by night. A few dim lights served to enable us to see about, but darkness was usually the signal for sleep; now, of course, all this is changed, and the present period, when developments in lighting are proceeding more rapidly than ever, is a fitting time to take stock of the situation.

Let us inquire, in the first instance, whether we are studying sufficiently closely how the light we are at such pains to produce should be actually applied? We may ask how much light is required for different purposes? What quality of light is desirable, what direction the light ought to come from, and how it should be distributed? All these are questions that now demand satisfactory answers.

We may indeed even go so far as to add one question more radical than any, whether, after all, we are doing wisely in proceeding on the course of turning "night into day"? We know how birds, for instance, are affected by climatic conditions. It has been an interesting experience at different zoological gardens in temperate climates to find that tropical birds do not thrive owing to the unequal periods of light and darkness interfering with their sleep. When artificial light was resorted to in order to reproduce the exact conditions of the tropics, the birds recovered their health and slept properly. The depressing effect upon miners of being obliged to work long hours in gloom and darkness is well known, and the melancholy nature of the night watchman's work is proverbial. In addition, it has been found that people who travel from one locality to another where the periods of light and darkness are very different suffer somewhat from this change, but they become acclimatised to the new conditions in time. Is it not, therefore, legitimate to inquire whether we ourselves may not experience certain effects due to physiological actions during the night time, which demand darkness, and whether our attempt to do away with a greater part of darkness might not be injurious to our health and sight?

DAYLIGHT ILLUMINATION.

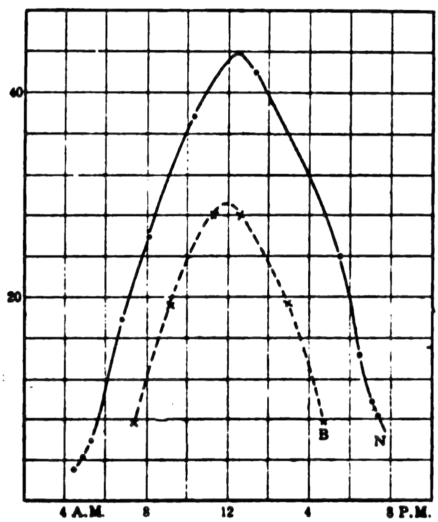
In all these perplexing questions, however, there is perhaps one guide on which we can rely even though we must not follow it too implicitly, namely, the qualities of natural daylight, to the best use of which our eyes have been gradually developed through countless generations. It is, therefore, desirable to say something regarding illumination of this kind, for our acquaintance with daylight conditions naturally modifies our impression of artificial methods of lighting. Yet here again, we must remember that daylight itself must be

* The Course consisted of four lectures, delivered on February 15th and 22nd, and March 1st and 8th. In re-arranging the material for publication in the *Journal*, the lecturer has preferred to divide it into six parts.

studied scientifically in order to use it to the best advantage. Both its quality and its intensity differ very greatly at places at different seasons, and at different times of the day. Weber in Germany, and Basquin, Nichols, and others in the United States have studied this question closely.

Some idea of the manner in which the illumination in a room may alter during the day, and at different periods of the year, will be understood from Figs. 65 and 66, which are taken from a paper by Dr. E. L. Nichols before the Illuminating Engineering Society in the United States in 1908. We must not be too ready to assume that because daylight is the natural method of illumination, therefore it can take care of itself and does not need proper attention.

FIG. 65.



Time of Day.

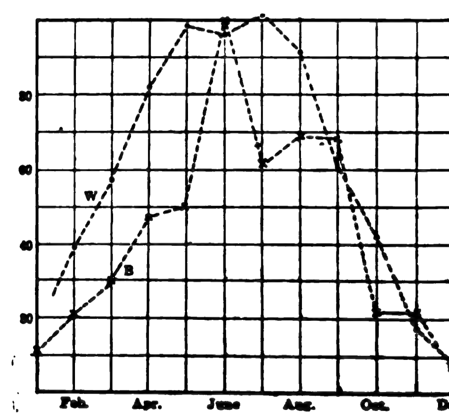
VARIATION IN INTENSITY OF DAYLIGHT DURING THE DAY.

N. Nichols (Tyrol).
B. Basquin (Chicago).

Naturally, provision must be made to secure that such illumination of buildings is sufficient to enable people to carry out their work with comfort. Indeed, it will be found that the actual intensity of illumination at different parts of a room lighted by daylight varies even to a greater extent that when illuminated by artificial light, according to the nature of the windows. In an office in Victoria-street with which I am acquainted, for example, a recent test showed that the intensity of illumination just inside the window at 10.45 a.m. was as much as 50 foot candles, whereas on a desk only 12 feet away from the window it was less than 1 foot candle. The matter of the careful study of daylight illumination in schoolrooms, on which I mean to touch on later, can hardly be over-estimated. When we consider how much work is carried out during the day time, we can see how important the study of the necessary conditions really is.

In passing, it might be of interest to mention that Mr. P. J. Waldram has recently been studying the measurement of daylight illumination from the architect's standpoint, and has found actual measurements of very great value in supporting the contentions in connection with cases of ancient lights in court. This is an instance of the unexpected directions in which the value of the measurement of illumination often comes to be felt.

FIG. 66.



Month of Year.

VARIATION IN INTENSITY OF DAYLIGHT DURING THE YEAR.

B. Basquin (Chicago).
W. Weber (Kiel).

I may also refer to the various efforts that have been made to specify the amount of a window space, &c., in schools and factories, and to pre-determine what the actual illumination is likely to be. For instance, in addition to Mr. Waldram's experiments (*Illuminating Engineer*, Vol. I., pp. 241, 811), Prof. Ruzicka has attempted to prepare a small artificial model of the room under consideration, illuminated by an artificial sky (*Illuminating Engineer*, Vol. I., p. 539).

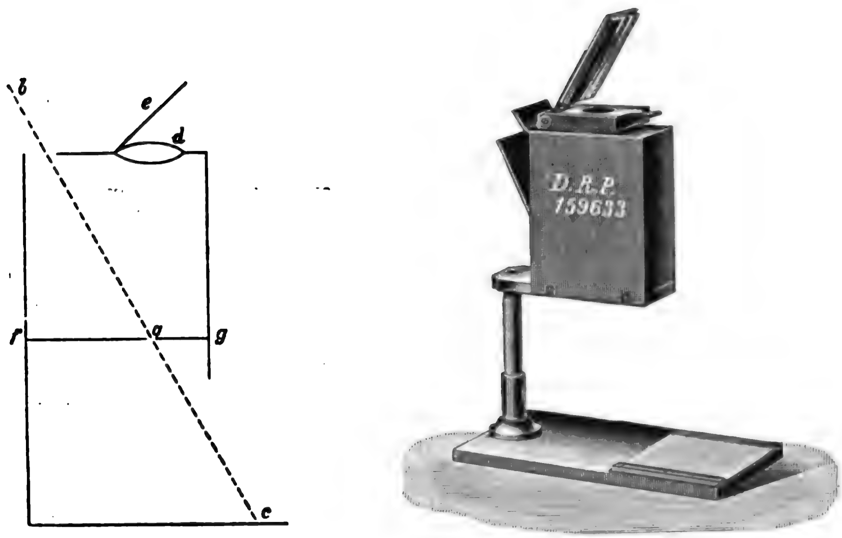
Naturally such a method of pre-determining the conditions of lighting in a building yet to be erected, might be of considerable value, for

it is not always easy for the architect to estimate beforehand whether the access of daylight to long corridors, or even rooms, is adequate.

Since the date of the lectures, Mr. Waldram has published some further results of the application of the above method of testing the daylight illumination to interiors. He has explained that under all ordinary conditions, a constant relation can be shown to exist between the intensity of illumination at a certain point in a room, and the unrestricted illumination out of doors. The value of this constant will, of course, depend upon many factors, upon the nature of the window space, the height of the houses opposite, and the reflecting power of the wallpapers used in a room, for example. But for a given room it will have the same value from day to day under widely different climatic conditions, and will, therefore, constitute a rough index as to whether the provision of daylight-access to a room is to be considered satisfactory or no. Of course it may happen that a room for which this constant is regarded as unduly low may nevertheless be sufficiently illuminated for a part of the day. But as seen above, this is not sufficient; we must prescribe conditions which render it highly improbable for the light ever to fall below the requisite minimum

Mr. Waldram considers that an office which enjoys 0·001 of the outside illumination at the centre of the room might be regarded as fairly satisfactorily illuminated, though, in the case of school children this figure might be deemed too low. In the article in question he quotes a series of figures for different buildings in London of which the following are a few examples :—

Fig. 67.



Thorner Illumination-Tester.

Proportion of Unrestricted Outside Illumination received by Interiors of Buildings.

New suburban elementary schools (children's desks)	0·0025 to 0·008.
New urban technical schools, ground floor average	0·001.
Ordinary offices, average at centre of room	0·001.
British Museum reading-room	0·007.
Royal Courts of Justice, Judges, seats	0·0007 to 0·0022.
House of Commons—	
Clerk's table	0·0008.
Speaker's chair	0·0009.
Members' seats	0·0003 to 0·0007.
House of Lords—	
Woolsack	0·0004.
Members' seats	0·004 to 0·0006.
Charing-cross Station Booking-hall	0·0001 to 0·0003.

Another simple form of apparatus for studying daylight-condition is that due to Thorner which is on exhibition to-night. This arrangement is shown in Fig. 67. The instrument is based on the same principle as that indicated by previous remarks, serving virtually to com-

pare the brightness of the sky at any moment (which is a criterion as to the outside unrestricted illumination), with the actual illumination in the room. By means of the lens, *d*, an image of the sky, reflected by means of the adjustable mirror, *e*, is formed at the paper, *fg*, in which there is a pinhole at *q*. The observer looking along the line, *bqc*, sees the white surface behind this pinhole at *c* and superimposed on this the image of the sky at *q*. Now the surface at *c* is illuminated by the available light in the room just as a book might be. If this illumination is too weak, the spot *q* appears black on a white surface; if, however, the illumination at *c* is to be judged satisfactory the contrary is the case. If the spot seems to be just equal in shade to the image of the sky the conditions are just on the border-line between what is to be considered adequate and what is not. It may be said that in many rooms no sky is visible and therefore the instrument cannot be applied, but it seems to be suggested that this in itself would lead one to consider the daylight conditions unsatisfactory.

The Reflecting Power of Wallpapers, &c.

While mentioning this matter reference may be made to the importance of bearing in mind the reflecting powers of the walls and furniture in a room and the great influence which such surroundings exert upon the available illumination. In any interior the effective illumination on a book or table consists only partially of the direct rays from the source of light. In addition, valuable assistance is rendered by the light reflected from surroundings. It is also preferable, physiologically, to avoid the extreme contrasts of very dark walls and gloomy surroundings, and the relatively bright surface of the book we are reading, or the paper on which we are writing. With this point we shall deal again in subsequently discussing inverted systems of lighting.

The general nature of the reflecting power of different surfaces will be gathered from the Table (p. 847) which has been compiled and presented before the Illuminating Engineering Society by Dr. Louis Bell.

The reflecting power of surroundings is naturally a matter which ought to be borne in mind by decorators and architects when advising as regards the furnishing and decoration of an interior. In such cases it is certainly to be desired that the architect, in whose hands the treatment of the æsthetic side of the problem mainly rests, and the engineer, who is concerned with the practical lighting arrangements, should work hand in hand. In the case of buildings of a more or less utilitarian character it may be recommended that the walls of the room should be in general light in shade but tinted and not pure white.

Before leaving this question it may also be pointed out that not only the quantity but the *quality* of light is affected by the surroundings. Thus in a room with red wallpapers the amount of reflected light usually suffices to give the illumination a distinctly reddish tinge, and this, of course, is not without effect on the appearance of coloured objects brought into the room. In the same way the colour of the surroundings must, to some extent, govern the colour of the illuminant which it is preferable to select. For instance, it would clearly lead to a certain loss of light and might be undesirable æsthetically to employ a source which was deficient in red rays and rich in green in a room in which the prevailing tint was red.

Intrinsic Brilliancy.

Turning now to artificial illuminants, I come to speak of one very important respect in which artificial illumination of the present day differs from daylight, namely, in intrinsic brilliancy. We have gradually become accustomed to the use of concentrated sources of light far brighter than the brightness of the normal sky. For instance, Dr. Stockhausen has given the following figures for different illuminants :—

Intrinsic Brilliancy of Various Illuminants (Stockhausen, Zeit f. Beleuchtungswesen, Oct. 10th, 1907).

Source.	Intrinsic brilliancy (c.p. per sq. in. of radiating surface, approx.).
Petroleum lamp	20
Incandescent mantle	35
Carbon filament glow-lamp ..	540
Metallic " " ..	1,100
Nernst " " ..	2,250
Arc light (Crater)	17,000

Average Intrinsic Brilliancy of Sky (Basquin).

3·5 candle-power per sq. in.

Minimum Intrinsic Brilliancy Recommended.

Stockhausen	4·2 c.p. per sq. in.
Woodwell (Ill. Eng. Soc., 1908)	0·1 " " "

Some other interesting figures on the same subject have just been published by Professor Barrows in his book on "Electrical Illu-

minating Engineering": these are given in the following Table:—

THE INTRINSIC BRILLIANCY OF VARIOUS ILLUMINANTS. (W. E. Barrows, *Electrical Illuminating Engineering*.)

Nature of Source.	Candle-power per sq. inch.
The Moor Tube	0·6
Frosted incandescent lamp	2-5
Candle flame	3·4
Gas flame	3-8
Oil lamp	3-5
Kerosene lamp	4-8
Cooper Hewitt lamp	16·7
Welsbach gas mantle	20-25
Acetylene flame	75-100
Enclosed a.c. arc depending on globe	75-200
Enclosed d.c. arc depending on globe	100-500
Incandescent lamp 4 watts per candle	300
Incandescent lamp 3·5 watts per candle	275
Incandescent lamp 3·1 watts per candle	480
Gem lamp 2·5 watts per candle	625
Tantalum lamp 2 watts per candle	750
Nernst lamp (bare)	800-1000
Tungsten lamp 1·25 watts per candle	1000
Sun on the horizon	2000
Flaming arc	5000
Open arc lamp	11000-50000
Open arc crater	200000
Sun 30° above the horizon	500000
Sun at zenith	600000

After each fresh departure in our methods of illumination, it invariably takes some time for people to get accustomed to the new conditions. It is interesting to recall the comments of the great chemist, Clement Desormes (see Cantor lecture by Professor W. Grylls Adams, F.R.S., 1881), who in 1819, when the gas light was first introduced, said:—

"The light is of a disagreeable yellow colour, entirely different from that red and warm gleam of oil lamps; it is of a dazzling brightness; its distribution will be impossible and irregular, and it will be much dearer than oil lighting; and, even if it should be improved, it will still remain much dearer than those lights which we already possess."

To-day, when we are accustomed to sources so much brighter than the flat flame gas burner this comment may seem amusing. But let us pause a little. It is in fact now realised by those who have studied illumination that this quality of intense intrinsic brilliancy is one of the seriously inconvenient qualities of modern sources of illumination. Most of you will at once concede how unpleasant is the dazzling effect of looking straight at an arc lamp, high pressure gaslight, or a naked metallic filament glow lamp at close quarters. You will find that after looking steadily at such a source for a few minutes, and then shutting the eyes, a distinct "after-image" is perceptible, which may appear to fade away in a few minutes, or even seconds, but which certainly corresponds to some abnormal, and therefore possibly injurious effect on the state of the eye.

In order to illustrate this point an analogy may be drawn with the action of a photographic plate. When a photographic plate receives a luminous image upon it, it is immediately affected and retains the image owing to a chemical change in its constituents. This only reveals itself when the plate is subsequently developed. But the plate can be kept undeveloped for some time, and though apparently unaffected as far as appearance goes the image is still there. Yet some observers have stated that, provided the plate is kept long enough, the image weakens with time, and has been known to fade away at last; the plate therefore seems to resemble the eye in recovering from severe exposure very gradually. This interesting analogy might well be made the subject of further study.

But on the other hand we know that an underexposed plate reveals but a faint image, and if the stimulus be sufficiently weak no perceptible image is retained at all. In the same way the eye, when exposed to a severe luminous impression, tends to retain the image afterwards and fails to recover immediately its normal condition; but an image which is not unduly bright passes away and leaves no apparent traces.

It might be mentioned that a very severe exposure indeed may produce local disturbances in vision which persist for a very long time; for instance, Prof. G. J. Burch has recorded inconveniences of this kind in his own case as the result of incautiously experimenting in connection with this very subject. In addition he has found that when we are removed into a completely dark room, these "after-images" on the eye sometimes seem to be still traceable after a couple of hours of complete rest.

We may also compare what happens when a photographic plate is exposed to a very bright object such as, for example, the windows in a somewhat subdued interior. Under these conditions we know that the image of the bright object is not sharply defined. There is "halation," and the outlines of the bright surface are surrounded by a misty halo owing to the spreading of the chemical effect beyond the proper limits. Even so our vision seems to

be impaired when gazing at bright objects. The filament of an incandescent electric lamp, for example, appears much thicker to the eye when incandescent than when in the unheated state.

Bearing in mind the order of brightness of the sky, which Prof. Basquin, as the results of experiments in the United States, extended over a long period, has estimated to be on the average in the neighbourhood of 3·5 candle-power per square inch, some authorities have recommended that the intrinsic brilliancy of sources of light liable to fall in the direct field of vision, should not exceed 5 candle-power per square inch. More recently, however, it has been felt that even this value was excessive in the cases of sources comparatively near to the eye, and Drs. Schanz and Stockhausen and also Mr. J. E. Woodwell (Paper read at the Annual Convention of the Illuminating Engineering Society, United States, 1908; *Illuminating Engineer*, Vol. I., p. 80) have recommended a value of the order of not more than 0·4 to 0·2 candle-power per square inch.

Before leaving this subject I should like to refer to the manner in which my previous comments on the subject of intrinsic brilliancy have been misconstrued, and in some cases, I fear, deliberately distorted. I urged, and with justice, when reading a paper before the meeting of the British Association at Leicester in 1907, that the new electric metallic filament lamps would undoubtedly have an injurious effect on the eyes if placed in the direct line of sight. In other words, this new source must be properly used and not abused. Unfortunately the gas interest in one of their publications utilised my warning without also mentioning in detail the circumstances under which it applied, thus giving the impression that I was responsible for the statement that the electric light was injurious to eyesight. I take this opportunity of pointing out that modern incandescent gas-lights used under the same faulty conditions, in the same careless manner, would also be objectionable.

I do not, however, wish to dwell on this aspect in any alarmist manner, but only to point out that this defect must be faced, and probably can be met by comparatively simple precautions. The obvious moral is that such bright sources ought to be kept out of the field of view of the observer, or if visible, their brilliancy ought to be suitably reduced by the effective use of shades. Apart from the possibility of physiological injury, common sense tells us how absurd it is to try to see any object with a bright source in between this object and the eye. If we are in a brightly lighted room our eyes adjust themselves to the brightness within but are incapable of seeing anything outside in the darkness; on the other hand, a person out in the dark can see into a lighted room without being seen himself. This fact ought to be borne in mind by the shopkeeper who deliberately places bright sources of light in front of his goods in his window; as a natural result the pupil orifice of the eye and the retina adjust themselves to this bright object and those objects which are only illuminated by a moderate intensity cannot be seen. In this connection I should like to speak with approval of the recent action of the City authorities in specifying that such bright sources should be screened in the direction facing the street, so as to avoid their tendency to dazzle the drivers and pedestrians. I may quote an effective motto recently put forward in one of the Holophane Illumination publications, "*Light on the object, not in the eye.*"

We may, in fact, regard it as an axiom that any source of light itself must be regarded as the crude product until it is effectively screened with a suitable diffusing shade; in America it has now become customary to supply "units" which consist of a source, perhaps an incandescent glow lamp equipped with a suitable reflector or globe, and seldom used without this combination. Indeed, so serious is the effect on the eyes of brilliant unscreened sources in the direct range of vision now felt to be, that I would almost consider the time ripe for definite governmental recommendations that such sources must invariably be provided with a suitable diffusing screen or shade, which will adequately protect the eyes.

There is really nothing very revolutionary in proposing recommendations of this description on such a vital point. But a few years ago, the importance of such questions as ventilation and purity of air was hardly generally realised, and those who insisted upon the need for supervision of these conditions in factories, were looked upon as extremists. At the present time, the importance of pure air, through gradual and persistent effort, has come to be so generally appreciated that factory inspectors are in a position to make strong recommendations on the subject, and even to prosecute when the conditions are clearly unjustifiable. And as interest in the subject has increased, so have methods of testing become more precise. At

the present day, valuable evidence can be obtained from the chemical analysis of samples of air in buildings, which are enclosed in small bottles, taken away by the inspector, and forwarded for examination to a central laboratory. Similar progress may be looked for in connection with illumination.

Another illustration of the result of convictions on hygienic matters gradually born home is the recent determined attempt to eradicate the objectionable habit of spitting. Once it came to be generally appreciated how vital was the importance of restricting this source of propagation of tuberculous disease the restriction met with little opposition. But what an outcry such a suggestion, interfering with the license previously enjoyed, would have raised a few years ago!

In the same way it may be suggested that a few wholesome regulations regarding obviously desirable improvements in existing methods of using light will soon be regarded as perfectly natural. It is quite as important to eradicate a foolish and unreasonable practice which is bad for the eyes, as it is to take due measures for the preservation of public health in other respects.

It may, therefore, next be of interest to discuss briefly a few of the methods of reducing the intrinsic brilliancy of illuminants by suitable shading.

Most of you are familiar with the use of the opalescent and opal glass for this purpose, and may know too that frosted glass has been very frequently utilised, especially in connection with electric lamp bulbs. In addition, in our drawing-rooms we frequently have recourse to silk shades in order to tone down the brightness of portable lamps distributed about the room.

Such methods may, of course, serve the purpose of producing a suitable diffusing surface; unfortunately, in so doing it is difficult to secure really adequate diffusion without at the same time losing an enormous amount of light.

I may mention, for instance, some data relating to the absorption of different types, which have been published by Professor J. T. Morris, Dr. B. Monasch, and Professor Barrows.

In addition, such methods only serve the purpose of reducing brightness; they are not effective in directing the light where required, or concentrating it on any particular spot.

These considerations have led to the introduction of a type of scientific glassware, of which we have some notable examples on exhibition. Cut glass has for a long time been utilised for the purpose of diffusing light sources. In the cut glass globes used until recently, however, such grooves as were made in the glass were only made quite haphazard, with the result that although a certain amount of diffusion was obtained, there was no attempt at direction, and the amount of light through any such globe having no appreciable diffusing power was very small indeed.

About 25 years ago, however, some experiments were carried out by Mr. A. P. Trotter in this country, and M. Blondel and subsequently by M. Psaroudaki in Paris, with the object of making scientific prismatic glassware which should not only absorb a minimum amount of light, but should diffuse it and also distribute it in any desired direction in a scientific manner. At that time the inventors may be said to have been far ahead of their age, and, therefore, we once more meet with an instance of early pioneering work in this country which has subsequently led to successful developments in illumination. For some years past the Holophane Company in the United States have taken up the question with great energy, and are manufacturing

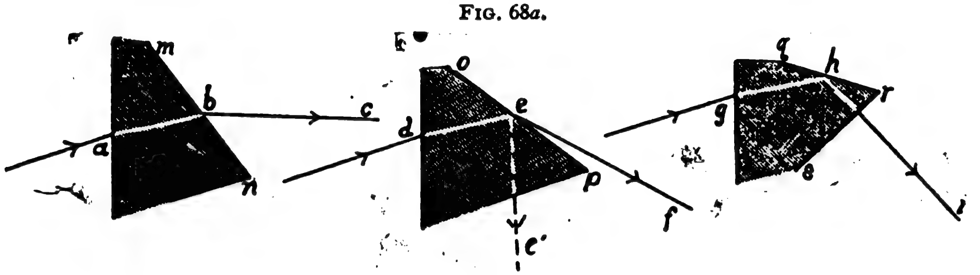
many models of fixtures of this kind for use with gas, electricity, or any other illuminant that may be desired, and designed specially with the object of utilising the light scientifically.

In this connection I might quote the action of the Franklin Institute in Pennsylvania, who in 1897 awarded the John Scott Legacy medal and premium to Messrs. Blondel and Psaroudaki, for their invention of a globe which secured much better diffusion and more satisfactory distribution than any other globe known to its members.

than was permitted by the simple prism arrangement.

When it is desired to distribute the light in a room, the individual rays from the source pass through the prismatic ribs and are reflected and refracted in a scientific and uniform manner so that each spot on the surface of the enclosing globe virtually becomes a new distributing centre; thus the light coming from the source is spread over an extensive surface, and the glare of the concentrated source is replaced by an apparently uniformly illuminated globe.

FIG. 68a.

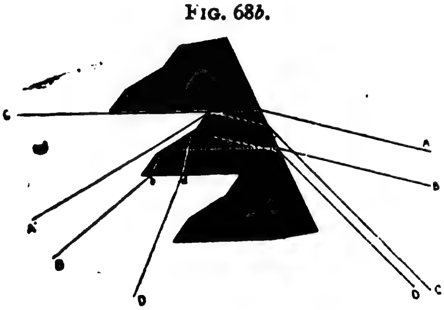


Refraction. Refraction and Reflection. Total Reflection.

The general nature of the prisms of which this scientific glassware is composed will be understood from Figs. 68a and 68b.

Fig. 68a shows the course of the rays through the simpler form of prism employed by the older inventors. It will be observed how the rays are bent out in different directions according to the inclination, and it will

FIG. 68b.



also be readily understood how, in utilising Holophane glass, it is essential to employ only a globe or reflector intended for use with the lamp for which it is specially designed. In Fig. 68b will be seen the more complete prismatic arrangement adapted by M. Blondel and M. Psaroudaki, which enabled the light to be spread over a wider angle and distributed more perfectly in the desired directions

In addition, this naturally serves to distribute the light effectually in all directions and to remove that "streaky" appearance, which is the result of the lack of uniformity in the distribution of light from most naked sources. The use of a shade of this kind also gives rise to a "soft" light; that is to say, there are no unduly sharp shadows. For instance, if the Holophane globe is removed and the lamp hangs naked below the metal holder the result is a dark shadow on the ceiling which appears irregularly illuminated; this, however, gives way to apparent uniformity and absence of shadow when the Holophane globe is replaced.

In many cases, what we chiefly desire is to distribute the light evenly in all directions, and Holophane globes may be designed with this object. In other cases, however, we desire the greater portion of the light to be reflected at a certain angle, in a downward or upward direction, and this, by a slight modification in the shape of the crystals, can also be done.

A number of examples of diffusing and concentrating Holophane globes and reflectors are on exhibition to-night. (Figs. 69, 70, 71, 72.) The glass reflectors are perhaps of special interest, because they are so designed that while concentrating the great bulk of the light in a downward direction where it is wanted, they also allow a small amount to pass in an

upward direction; therefore we may mount a a suitable silk shade over such a reflector and we shall have the advantages of efficient reflec-

FIG. 69.

HOLOPHANE CLUSTER.

FIG. 70.

HOLOPHANE REFLECTORS ENCIRCLING LAMPS WITH FROSTED TIPS.

tion, and yet enough light coming upwards to make the shade appear ornamental. Metal reflectors do serve the purpose of concentrating the light, but, of course, have not the above-mentioned property.

Glass ware of the Holophane type can be applied with success to all the various methods of illumination, gas, oil, electric light, &c., and new designs are constantly brought out to suit the different types of lamps as they come upon the market. One feature of special importance, as mentioned previously, is the supply of a given lamp, with its appropriate shade, as a single unit. In this way the most efficient results are secured to the consumer who is taught to consider any lamp incomplete unless

FIG. 71.

HOLOPHANE DIFFUSING GLOBE.

it is properly shaded. I have dwelt on this matter in some detail because during my recent visit to the United States, where scientific illuminating engineering has received so much attention, I found that this scientific glass was very widely used.

INDIRECT LIGHTING.

While speaking of methods of diffusing light mention may be made of the inverted system of lighting by means of which all the direct rays of a source are thrown on the ceiling, and the eye therefore receives no direct rays and an approximately shadowless illumination can be obtained. Formerly this method was

used in connection with arc lights and high-pressure incandescent gas lights, but the coming of the high candle-power efficient metallic filament glow lamp may lead to its more general adoption than hitherto. Figs. 74 and 75 show some examples of this method, recently described in a paper before the Illuminating Engineering Society of New York.

respect when the walls of the rooms were very light in texture. If the book we are reading is somewhat brighter than the surroundings, however, our attention is involuntarily rivetted on the page, and when our eye does stray away it is rested by the more subdued tone of the surfaces on which it plays. On the other hand, it is pointed out, when there is light everywhere the eye gets no such rest.

Fig. 72.

Holophane Globes in Position Illuminating a Verandah.

At one time the production of an entirely shadowless illumination was held to be very desirable, as it corresponded with a close resemblance to daylight conditions. More recently, however, illuminating engineers have come to feel that an intermediate condition of things is desirable. We do not want very sharp contrasts of light and shade, which are admittedly trying to the eye, but, on the other hand, artistic and even utilitarian requirements rarely favour entire lack of shadow.

It had been suggested, for instance, that, when reading a book, we do not desire the surroundings to be too bright in comparison, for this tends to distract attention. It has recently been found in New York that indirect systems were sometimes inconvenient in this

But we must certainly avoid going to the other extreme. Dr. Louis Bell, for instance ("The Physiological Basis of Illumination," Proc. Am. Academy of Arts, 1907) has pointed out that it is very undesirable for a desk to be brilliantly illuminated while the surroundings are in complete obscurity. Under these conditions the eye is not rested when it strays from the book, but receives a positive shock owingto the change in the conditions. Each time it turns away, the pupil-aperture and the retina attempt to accommodate themselves to the darkness, and, having done so, are called upon to reverse the process once more, when attention is again bestowed on the brightly-illuminated book on the desk.

Fig. 76, which is taken from the communication of Dr. Bell to which reference has just been made, is presented as a bad example of extreme contrast in this respect.

As an illustration of an attempt to secure more uniform conditions for desk lighting, we may take Fig. 77, which shows a desk illuminated by the diffused illumination from a Regina arc lamp hung high up. Probably it will eventually be recognised that the wisest course in this matter is an intermediate one. Thus we shall feel it advisable to secure a fairly low, subdued general illumination—such as may conveniently be produced by an indirect method of lighting—and to superimpose a stronger local illumination at the desk or table where we wish to work, and on which we wish to concentrate our attention. It will be seen, therefore, that it must not be too readily assumed that inverted lighting pure and simple, which some people have supposed to be the closest equivalent to daylight condi-

tions, is necessarily invariably the ideal method of lighting.

Photometry.

Let me now turn to one branch of the subject of illumination, as it is considered at present, in which very great developments have been made in recent years, namely, the science of *photometry* and the *measurement of light and illumination.* Now, this is a very vast subject, which has been very fully treated by Sir William Abney, Mr. Dibdin, and by the authorities who have lectured before this

Fig. 74.

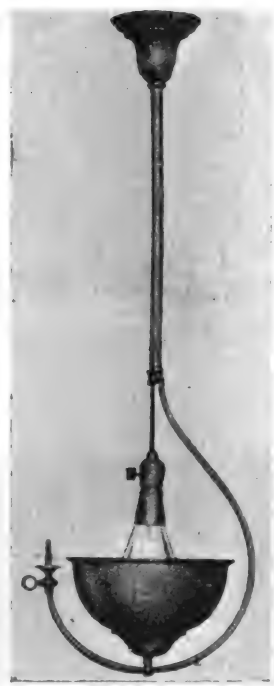
Twin Inverted Electric Fixture.
(A. D. Curtis and A. J. Morgan, "Trans. Illum. Eng. Soc." 1908).

Society in the past. I cannot hope, therefore, to go into details, but only to refer to one or two respects in which there have been such striking modifications from the point of view from which these matters are regarded.

At one time photometry was regarded merely as an interesting and perplexing scientific playground. Its vital application to practical problems was hardly realised. To-day matters are very different. We have at our disposal a bewildering choice of illuminants, many of them competing very closely in certain fields, and we need every method available of discriminating between their respective values. People now realise that the fundamental use of a source of light is to *illuminate*, and, therefore, it is obviously essential to systematise our methods of comparing their illuminating powers ; photometry, therefore, has become an art of industrial importance.

There have of late been a large number of ingenious types of photometers brought forward, so that to-day we have a choice of a number of excellent instruments, where a few years ago there were, perhaps, only two or

Fig. 75.



Combined Gas and Inverted Electric Fixture.

(A. D. Curtis and A. J. Morgan, "Trans. Illum. Eng. Soc." 1908).

three that were generally known. We have seen, for instance, the development of the "Flicker" photometer as a means of comparing the brightness of sources which differ in colour.

Illumination - Photometers.—But perhaps the most striking in principle has been the introduction of instruments intended to measure, not the illuminating power of sources, but the actual illumination available in the street, or at the table at which we sit.

Naturally, it is essential to have a method of comparing the illuminating power of sources,

but this after all, though of technical importance, is only a step towards the attainment of our ultimate desires. What we really desire to know is the actual working illumination available.

In this connection, it is very interesting to recall some words of Sir William Preece, in a paper before the Royal Society, in 1883:—

"I have long felt," he said, "that to meet the case of electric lighting illumination, we must not depend

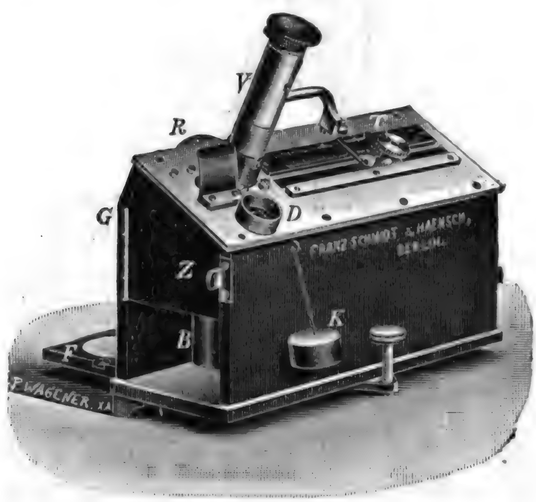
he plaster of paris surface, F, receives the general illumination, the intensity of which it is desired to measure. The rays from this surface pass into the telescope of the instrument at *b*; its brightness is compared with that of the frosted glass, *m*, illuminated by the small benzine lamp, B, the rays from which enter at *a*. The flame-height of this lamp is regulated to exactly 20 mm., this height being controlled by observations through the window at D. The rays from the benzine lamp, before proceeding to illuminate the plate, *m*, must suffer reflection from the pair of mirrors, S_1, S_2, as shown. By moving these mirrors to and fro by means of a rack and pinion arrangement, we can weaken or strengthen the brightness of the illuminated plate, *m*, and can determine the relative values of the intensity of illumination, corresponding to equality of brightness in the field of view, by means of a scale calibrated direct in lux.

This alone would enable a range of illumination of 15 to 1 to be measured; in addition, a disc, *r*, is inserted in front of the plate *m*, which contains a series of graduated smoked glasses, the densities of which are such that the illumination read upon the scale must be multiplied by 0·01, 0·1, 1, 10, and 100 respectively.

upon any direct comparison between the light emitted by the source to be measured, and a given recognised standard of light; but that we should rather make our standard of comparison an area illuminated to a given intensity whatever be the source of light. We do not want to know so much the intensity of the light emitted by a lamp as the intensity of the illumination of the surface of the book we are reading, or of the paper on which we are writing, or of the walls on which we hang our pictures."

FIG. 78c.



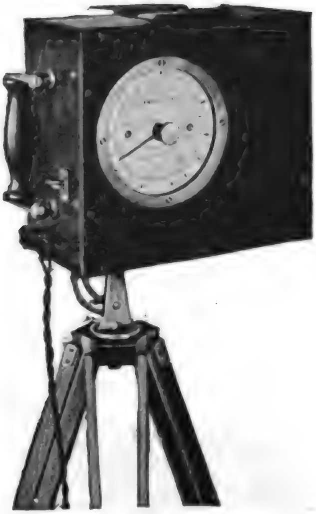
General View.

THE MARTENS ILLUMINATION-PHOTOMETER.

Moved by these considerations, Sir William Preece and Mr. A. P. Trotter were among the very earliest in this country to devise the "Illumination-Photometer," or, as they are now sometimes called, "Illuminometers."

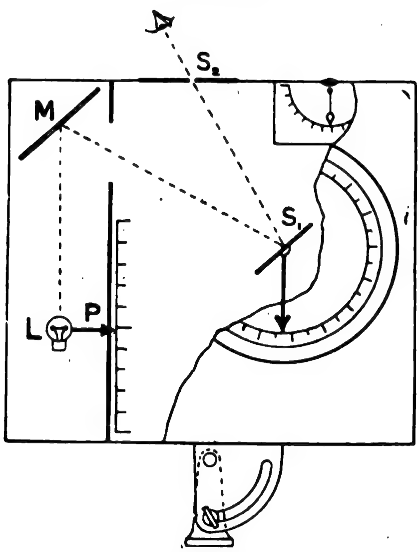
Quite recently the development of an interest in illumination has led many to realise the practical importance of such instruments, and types have been designed in England by Mr. H. T. Harrison, Messrs. Everett Edgcumbe and Co., Messrs. Alexander Wright and Co., and others. For a description of these and other instruments I should like to refer you to a lecture delivered by Mr. J. S. Dow at the Municipal Building and Public Health Exhibition in 1908 (see *Illuminating Engineer*, Vol. I, 1908, pp. 493-506). In addition a very large number of these instruments have been brought forward in Germany and the United States, and some of them formed the subject of an interesting paper by Mr. Preston Millar at the First Annual Convention of the Illuminating Engineering Society in 1907. What I wish to impress upon you is, however, that we

FIG. 79*a*.



EVERETT EDGCUMBE ILLUMINATION-PHOTOMETER. (General View.)

FIG. 79*b*.



EVERETT EDGCUMBE ILLUMINATION-PHOTOMETER. (Sectional View.)

The comparison source of light is in this case a small glow-lamp, L, the rays of light emitted by which strike the mirror, M, and are thus reflected on to the white diffusing screen, S_1, receiving the illumination it is desired to measure. The observer looks at the white diffusing screen, S_2; in this is cut a small aperture with very sharp edges. The observer is thus able to compare the brightness of the actual illumination of the surface, S_2, with that of the screen, S_1. The latter can be rotated so that the light strikes it at various inclinations, and the illumination is thus altered through a definite and convenient range from zero to two candle-feet. The actual value in candle-feet is obtained by observation of a pointer attached to the screen, S_1, moving on a scale on the outside of the box containing the photometer as shown in the diagram.

FIG. 80*a*.

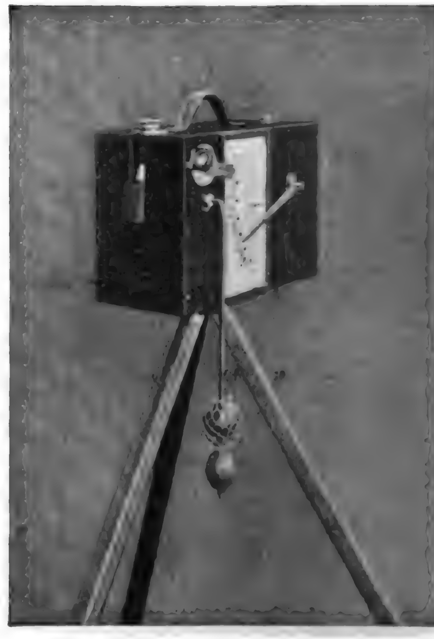


FIG. 80*b*.

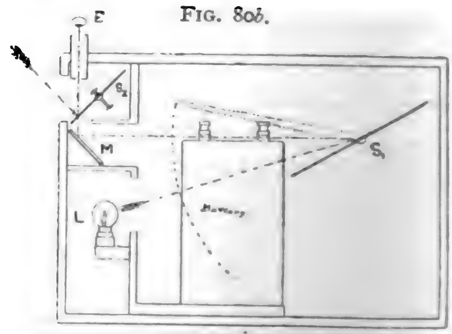


HARRISON UNIVERSAL PHOTOMETER
(Messrs. Elliott Bros.).

The standard of light consists of a small glow-lamp at L, which receives current from a small accumulator within the instrument, and which illuminates the moveable screen S_1. S_2 represents a white sector-disc (*i.e.*, a disc from which two symmetrical sectors are cut out) which is driven by means of a small air-blast at any desired speed; on this screen is received the illumination which it is desired to measure.

The eye of the observer at E sees, in rapid succession, first the illuminated white surface of the sector S_2, and then, in the mirror M, the illuminated surface of the screen S_1. All that is necessary, therefore, is to alter the inclination of the screen S_1 until no flicker can be perceived by the eye. The surfaces S_1 and S_2 then appear equally bright. The actual illumination at the screen S_2 can be read off by the reading of a pointer attached to S_1, and moving on a scale graduated in candle-feet. In the position shown in the diagram the photometer is arranged to measure the intensity at an angle of 45 degrees to the vertical, but, by tilting the photometer, the intensity at any measured angle may also be obtained.

In a recent modification of the instrument provision is made for the observer to use the instrument *either* on the flicker or equality of brightness plan, and also for the measurement of illumination in a horizontal plane to be accomplished.

FIG. 81.

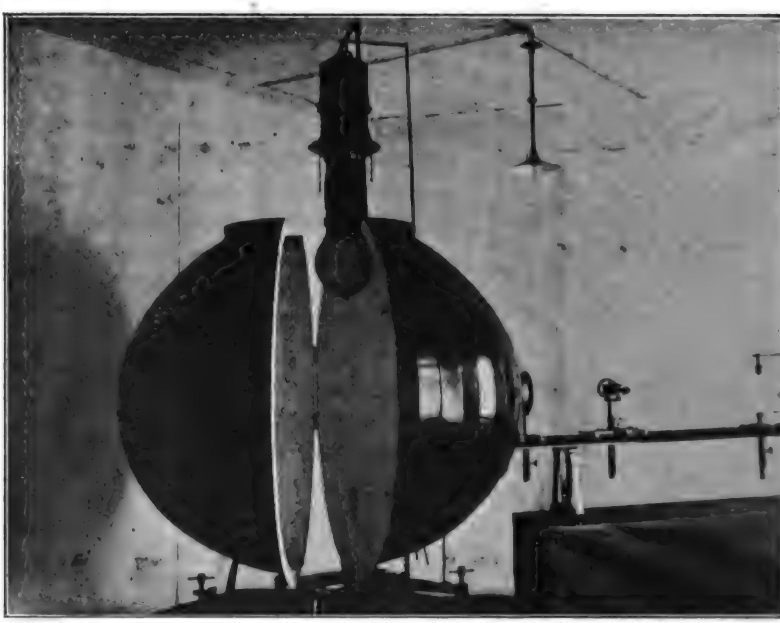
GENERAL VIEW OF THE GLOBE-PHOTOMETER.

(*See* Bloch, *Illuminating Engineer*, Vol. I., 1908, p. 280.)

have now available actual instruments for the measurement of illumination as opposed to light, and that, therefore, we may hope in the future to be able to specify the amount of illumination to be required to read by or for any other purpose, just as a grocer supplies one pound of tea neither more nor less—that is, if he is an honest grocer.

The Globe Photometer.—In passing, I may also mention one important development in light measurement, namely, the introduction of so-called integrating and globe-photometers, which are instruments devised to enable the total amount of light in all directions from a source to be obtained by a single measurement.

FIG. 82.



VIEW OF ULBRICHT GLOBE PHOTOMETER: THE GLOBE IS DIVIDED IN ORDER TO RENDER ITS INTERIOR ACCESSIBLE.

Fig. 81 and 82 display typical Ulbricht Globe Photometers; this instrument was discussed very fully by Dr. L. Bloch, Dr. Corsepius, and others in recent articles contributed to the *Illuminating Engineer* (Vol. I., 1908, pp. 274, 553, 801, &c). For detailed information readers are referred to these articles.

Briefly, however, the principle of the instrument is as follows:—The source, the light from which we desire to measure, is inserted within a hollow sphere, the interior surface of which is coated with some white diffusely-reflecting material. All the rays from the source in all directions are then reflected to and fro within the globe so that the intensity of illumination of the inner surface ultimately comes to be a measure of the total amount of light given out by the source. If need be the two hemispheres may be first separated as in Fig. 82 and the lamp placed inside. The two halves can then be closed again and the illumination of the inner surface studied through a little observation window. As a rule, it is unnecessary to open the globe, the lamp to be tested being merely lowered through a suitable hole at the top. As will be seen from these illustrations such globes are frequently of considerable size. This is necessary because the theory of the instrument demands that its dimensions should be as large as possible in comparison with the lamp studied, and the instrument is frequently used for the testing of large arclamps, &c.

I wish to repeat, therefore, that the subject of the measurement of light is now being lifted out of the state of uncertainty in which it so long existed, and is now coming to be looked upon as a feasible and recognised process.

The International Unit of Light.—And lastly, let me dwell upon one aspect of this subject which is particularly satisfactory. I allude to the efforts that are now being made

to establish measurements of light on a definite international basis. At one time the units of light in different countries were very different, and, as the general public and even the great majority of engineers did not realise this, much confusion naturally arose in expressing the intensity of different lamps. In addition, the actual methods of carrying out photometrical tests differed very much in different countries, and also (as they do even to-day) between representatives of different systems of lighting even in the same country. Within the last few years, however, Government laboratories have been established in the chief countries of Europe and in the United States, and a determined effort has been made to bring matters to a common basis, and to decide accurately the relations between the standards used in different countries. For this purpose carefully standardised glow lamps are now regularly exchanged and compared between the chief laboratories in England, France, Germany, and the United States. There is now, therefore, no fear that these standards may not be maintained constant, and their relation is accurately known.

The next step will be for all the nations to agree upon a common unit of light, and I am glad to say that considerable progress has been made in this direction, and that a fair share of the credit attaching to these efforts is due to the Illuminating Engineering Society in the United States, who have been working in harmony with the American Institution of Electrical Engineers, and the American Gas Institute, for the furtherance of this end. It cannot, however, be too strongly emphasised that no such agreement could be of permanent value unless it satisfies not only representatives of different countries, but also different representatives of the different systems of lighting in use in those countries. It was with the object of urging this view that I was present at the meeting of the International Electrotechnical Commission in this country last year, and strongly supported the recommendation on that occasion that no definite steps should be taken until an opportunity was provided for the expression of the views of those representing not only electric lighting but also gas and other systems. I am glad to say that this has been borne in mind by the sub-committee dealing with the standard of light, who have co-opted Mr. J. W. Helps and Dr. C. V. Boys, as representatives of the gas industry, and the gas referees.

[Since the date of this lecture an important announcement has been made simultaneously by the recognised official photometrical laboratories in Great Britain, France, and the United States on the subject of a proposed international unit. The ratios between units employed in the chief European nations and the United States have recently been redetermined, and it has been found that those used in France and this country are in practical agreement; the American unit was 1·6 per cent. higher than both, and the German unit 0·9 times this value. The United States have now agreed to lower their unit by 1·6 per cent. so that in future one and the same unit will be employed in Great Britain, France, and the United States, while the value employed in Germany is related to the international unit by the convenient fraction 0·9. Some objection to the term "international unit" has been raised in Germany on the ground that the existence of such a unit strictly demands an adequate international standard (which we have not as yet succeeded in obtaining). But whatever view may be taken in this matter, the practical agreement attained between the units in these three countries is a very satisfactory simplification, and the United States deserve our gratitude not only for having taken up the matter so sympathetically, but also for making a certain concession in lowering their unit as explained above. It may be mentioned that M. Blondel has recently pointed out that a proper name for the international unit is needed and propose the Greek terms "Phos" or "Pyr," or the contraction of a scientist's "Vi" for "Violle" (*Illuminating Engineering*, London, Aug., 1909.)]

One by one, therefore, the various misunderstandings characteristic of photometry are being removed, and we may hope to see in the future this method of measuring recognised to be as definite a process as the measurement of gas, or electricity, or even weight.

THE MARINE STEAM TURBINE.*

The rapid development of the marine steam turbine during the last seven years, constitutes one of the romances of engineering, and the magnitude of the work done and the revolution initiated by Mr. Charles Parsons will be more justly appreciated hereafter than it can be at present. In some quarters there is a tendency to deal critically with details, and to disregard broader views of the situation as it stands to-

* Extracted from the Presidential Address of Sir William H. White, K.C.B., F.R.S., to the Engineering Section of the British Association, Winnipeg, 1909.

day. In May, 1909, there were 273 vessels built and under construction, in which steam turbines of the Parsons type are employed, the total horse-power being more than three and a half millions. In the Royal Navy, every new warship, from the torpedo-boat up to the largest battleships and armoured cruisers, is fitted with turbine engines; and the performances of vessels which have been tested on service have been completely satisfactory, in many instances surpassing all records for powers developed and speeds attained. In the war-fleets of the world this example is being imitated, although in some cases it was at first criticised or condemned. In the mercantile marine, as a whole, while the new system has not made equal advance, many notable examples can be found of what can be accomplished by its adoption. It is now admitted that steam turbines enable higher speeds to be attained in vessels of given dimensions; and in steamers built for cross-channel and special services, where high speed is essential, and coal consumption relatively unimportant, turbines have already ousted reciprocating engines. For oversea service and long voyages an impression has existed that the coal consumption of turbine-engined ships would considerably exceed that of ships driven by triple or quadruple expansion reciprocating engines. Critics have dwelt on the reticence in regard to actual rates of coal consumption practised by owners of turbine steamships. Naturally there are other reasons for reticence than those which would arise if the coal consumption were excessive; but pioneers in the use of turbine machinery may reasonably claim the right of non-publication of results of trials in the making of which they have incurred large expenditure, and taken considerable risks if they think that silence is beneficial to their business interests. Even if it were true that in the earliest applications of the new system economic results had not been obtained equal to those realised in reciprocating engines which have been gradually improved during half a century, that circumstance should not be regarded as a bar to acceptance of a type of engine that admittedly possesses very great advantages in other ways, but should be regarded as an incentives, to improvements that would secure greater economy of coal. The evidence available, however, does not confirm the adverse view, and those familiar with the facts do not admit its truth. One example may be cited as it affects the Canadian service. In June, 1907, it was authoritatively stated that in the Allan liner *Virginian* the reports which had been circulated respecting the excessive coal consumption were unfounded, that the vessel was making passages at speeds of 17½ to 17¾ knots, as against the 17 knots estimated, and the rate of coal consumption was really about 1·4 lbs. per indicated horse-power which would have been required to attain this speed if the vessel had been fitted with reciprocating engines. This result compares well with the consumption in ordinary passenger steamers running at high speeds in proportion to their dimensions, although in large cargo steamers and vessels of the intermediate type, working under much easier conditions and at very low speeds in proportion to dimensions, lower rates of consumption may be obtained. With these latter vessels the fair comparison is the combination system and not the pure turbine type which is adapted for high speeds.

The crowning triumph of the marine steam turbine up to the present time is to be found in the great Cunard steamships *Lusitania* and *Mauretania.* The passages made this year by the latter ship since she was refitted have been marvellously regular, and the 25 knots average across the Atlantic, which was the maximum contemplated in the agreement between the Government and the Cunard Company, has been continuously exceeded. As one intimately concerned with the design of the *Mauretania*, who has had large experience in ship design, has made a life-long study of the laws of steamship performance, and had the honour of serving on the committee which recommended the employment of turbines in these great ships, the writer ventures to assert that equal results could not possibly have been obtained with reciprocating engines in vessels of the same form and dimensions. Contrary opinions have been expressed, but they have been based upon incorrect data or have omitted consideration of the fact that in vessels of such great engine-power it was necessary to have time to perfect the organisation of the staff in order to secure uniform conditions of stoking and steam production, and to bring the "human element" into a condition which would ensure the highest degree of efficiency in working the propelling apparatus. This necessity for time and training has been illustrated again and again in the case of new types of Transatlantic steamers, including some which held the record for speed prior to the appearance of the Cunarders. In the *Lusitania* and *Mauretania* the engine-power is fully 60 per cent. greater than that of their swiftest predecessors, yet no similar allowance appears to have been thought necessary by some critics, who assumed that performances on the earlier voyages represented the maximum capabilities of the vessels. Subsequent events have shown this view to be fallacious and have justified the recommendation of the Turbine Committee and the action of the Cunard directors. Allegations made in regard to excessive coal consumption have also been disproved by experience; and in this respect the anticipations of the committee and of Mr. Parsons have been fully realised.

The marvellous regularity maintained by the *Mauretania* on a long sequence of consecutive Transatlantic passages—made under varying and in many cases very adverse conditions of wind, weather, and sea—illustrates once more, and on an unprecedented scale, the influence which large dimensions have upon the power of maintaining speed at sea. Starting from the eastward passage, beginning on February 3rd last, and taking twelve passages (westward and east ward) which followed, the average speed for the

thirteen passages, approaching 40,000 sea miles in length, has been 25¼ knots; the lowest average speed in the series has been 25·2 knots, the highest average speed 25·88 knots. Many of the winter passages in this series were made in winter weather against strong winds and high seas, which would have considerably reduced the speed of her predecessors, but had small influence on the *Mauretania*. In many instances delays have been caused by fogs.

On seven consecutive passages made since the beginning of last May the average speed of the *Mauretania* in covering about 20,000 sea-miles has been 25·68 knots, the minimum speed for the passage having been 25·62 knots, and the maximum 25·88 knots. On her contract trials, the *Mauretania* maintained an average speed of 26·04 knots for a distance somewhat exceeding 1,200 knots, the steaming time being rather less than forty-eight hours. On the passage when she averaged 25·88 knots, she ran 1,215 knots from noon on June 17th to noon on June 19th (about forty-six hours), at an average speed of 26·23 knots, and by noon on the 20th had covered 1,817 knots at an average speed of 26·18 knots for 69 hours. The ship has, therefore, surpassed on service her performance on the contract trial.

In view of the foregoing facts and of others of a similar nature, it is reasonable to assume that as experience is enlarged and information is accumulated in regard to forms of propellers likely to prove most efficient in association with quick-running turbines, sensibly improved performances will be obtained. At present, in comparisons made between the efficiency of reciprocating-engined ships and turbine-engined ships, the former have the great advantage attaching to long use and extended experiment; but this is not a permanent advantage, and it may be expected that, good as the position is to which the marine steam turbine has obtained in the brief period it has been in practical use, that position will be gradually improved. Whether or not other forms of propelling apparatus in their turn will surpass the steam turbine it would be unwise to predict. Internal combustion engines are regarded in some quarters as dangerous and probably successful rivals to steam turbines in the near future. Within certain limits of size, internal combustion engines no doubt answer admirably; but as dimensions and individual power of the engines are increased, the difficulties to be overcome also rapidly increase, and the fact is fully recognised by those having the best knowledge of those types of prime movers. On the whole, therefore, it seems probable that the turbine will not soon be displaced, whatever may happen eventually.

THE MINING INDUSTRIES OF GREECE.

Greece is peculiarly a mineral-producing country, possessing many mines, especially of iron, lead, zinc, silver, &c. The mines are found chiefly on the eastern shores of the peninsula and in the islands of the Ægean, as these parts of the country are the oldest geologically, and of volcanic origin. Notwithstanding this mineral wealth, the industrial development of the country has been slow, on account of the lack of fuel, which is nowhere found in sufficient quantity. For this reason most of the minerals are exported in a crude state after the simplest possible preparation, and the exploiting only of those metals has been found to be profitable which are valuable without being bulky, and are easily mined and transported. Recently also, on account of the rise in the value of the paper drachma, mines have been shut down which formerly were worked with profit. Labour and other expenses must be met now with paper that is worth nearly its face value in gold. The following mines are in operation:—Hematite iron ore mines in Laurium, Skyros, Kythnos, Siphnos, Seriphos, Antiparos, Mykonos, Atalante; manganese iron ore mines in Laurium, Kimolos, and Syra; chrome iron ore mines in Larymne; lead ore mines in Laurium, Siphnos, and Thera; zinc mines in Laurium, Siphnos, Antiparos; manganese mines in Milos; chromium mines in Pharsala and Lamia. But for the lack of coal Greece would have been an important steel and iron producing country. Experiments are being made as to the possibility of using lignite for smelting purposes, of which considerable quantities are found. According to the American Consul at Athens, the iron ores are hematite, generally of high grade, and manganese in veins piercing limestone or volcanic layers. Often, as at Laurium, they appear as coverings for beds of lead, zinc, and copper. One of the best mines in Greece, now being worked, is found in the island of Seriphos. This mine produced and sold during the years 1901 to 1907 iron ore valued at £428,000. Activity in iron mining fell off considerably in 1908 on account of the crisis in America, on the Continent, and in Great Britain. The lead ores are found for the most part between volcanic strata, in the form of lead sulphide. Mines of this kind exist in the island of Mykonos. At Laurium the iron is found between layers of schist or marble, together with ores of zinc and iron carbide. These mines were worked from ancient times, and the smelting was done on the spot. The residue of the lead, cast aside by the ancients, is worked over to-day by the Greek Mining Company of Laurium. The ancients neglected also the zinc ore, the utility of which was unknown to them, and this is found as thrown out by them, and carefully worked. Deep mining is limited at Laurium on account of the water, which rises everywhere to a slight distance below the level of the sea. Zinc is also mined at Laurium. The zinc oxide is exported in its natural state. There are also here kilns for the roasting of the lead oxide. Other mineral products in Greece which are taken out at a profit are emery, magnesite, gypsum, kaolin, and sulphur. Many other mineral substances exist in Greece of possible value, which have either not been worked at all or only worked on a small scale. Among these may be

mentioned talc, chalk, ochre, baryta, &c. The quality of emery depends upon the percentage of corundum it contains and the quantity of iron in mixture. Pure corundum is not found. It is used for the polishing of hard substances, and is, therefore, of great industrial value. The world's annual production of emery is about 35,000 tons, of which Greece produces 9,000 tons from the island of Naxos. The right of mining the emery is enjoyed by the inhabitants of certain districts, the Government transporting the product to Syra, where it is sold for about £4 per ton. The Naxos emery contains about 60 per cent. of corundum. Magnesite is of great industrial value on account of its resistance to heat, which renders it suitable for the lining of furnaces and for fire-bricks. It is also used for making cement. Magnesite is found principally in the island of Euboea. It is mined by the Company of Municipal and Public Works, the Anglo-Greek Company, and the Magnesite Company. In the island of Milos are found gypsum and sulphur, and its millstones are famous throughout the East. It is said that the mining industry is capable of great development in Greece, and that many mines that are at present neglected, and others that have not yet been discovered, will be worked profitably in the future.

COMPULSORY PILOTAGE.

The Board of Trade Committee, under the chairmanship of Sir Kenelm Digby, K.C.B., formerly Under Secretary of State at the Home Office, which has been appointed to consider and report on the Pilotage Laws, and to which reference was made in a note on page 792 of the *Journal*, has a very thorny topic to examine, and one very productive of litigation in the past. The last exhaustive inquiry into the matter was made by the Royal Commission on the Port of London in 1900–1902, and much striking evidence was elicited. So far as London is concerned, pilotage is regulated by the Trinity House Corporation, who exercise jurisdiction in respect of 37 "outport" districts as well. But nearly all the more important ports in the British Isles have pilotage authorities of their own, *i.e.*, a Standing Committee or a special statutory Pilotage Board, and thus are independent of the Trinity House. The most vexed question in pilotage matters, however, is the maintenance of compulsory pilotage on the Thames and in certain other ports, where it is generally regarded as a very serious grievance, especially by wharfingers and barge-owners. The original rule was that all pilotage should be compulsory within the London district and the Trinity House outport districts, but the rule, as was pointed out in the *Journal* of the 13th August, practically ceased to be a rule, owing to the multiplicity and complication of the exceptions, and, in the words of the Royal Commission, "the whole law is in a chaotic condition, and is a fruitful source of litigation and trouble." According to the Merchant Shipping Act of 1894, which, however, was mainly a consolidating Act of previous enactments, an owner or master of a ship is not answerable for loss or damage occasioned by the fault or incapacity of any qualified pilot in charge of that ship in districts where pilotage is compulsory. The legal principle upon which this rule is founded is that a man is liable for the acts of those he voluntarily employs, but not for the acts of those whom he is compelled to employ. Unfortunately, however, this leads to an inversion of what has been laid down by the Admiralty as the true rule, *i.e.*, that a pilot should be the adviser of the captain, but should not take his responsibilities. It may thus be imagined what a confusion arises, and instances of the most extraordinary anomalies and injustices were given by various witnesses before the Royal Commission. It was hoped the Commissioners would have seen their way to recommend the abolition of compulsory pilotage altogether, and the transfer of buoying and pilotage within the limits of the Port of London to the new authority. The latter reform was duly recommended by the Commissioners (but not included by the Government in the Act), and, with regard to the question of compulsory pilotage and the peculiar hardship of the exemption of ships when in charge of a pilot from liability for damages, the Commissioners left it to the new Port Authority for London to apply to the Board of Trade for a provisional order exempting all ships in the Port of London from compulsory pilotage. As the Port Authority is now in full swing it would be, of course, within their competence to apply for such an order. But, no doubt, the Board of Trade feel that if so important an amendment of the general law be carried out it is better it should be preceded by a special inquiry *ad hoc*, and not upon the initiative of a local authority, however powerful or dignified. Hence the new Committee, the proceedings of which will be undoubtedly watched with attention by shipowners, bargeowners, wharfingers, and other great river business interests.

RABBITS AND SHEEP IN AUSTRALIA.

A correspondent of the *Economist* contributes some interesting information relating to the damage done by rabbits to the grazing districts of Australia. At the present day Australia depastures nearly 100,000,000 sheep; but, vast as this number is, a leading South Australian has given it as his opinion that "the country is carrying a greater weight of rabbits than of sheep." Accounts from various squatters seem to confirm this opinion; in any case, it is a matter of fact that the rabbits have driven out of great districts both the sheep and their owners, rendering the country so abandoned quite useless.

The fecundity of rabbits is appalling. Naturalists reckon that under favourable circumstances, such as obtain in Australia, a single couple will increase to four millions in five years; and certainly in the 35

years that have elapsed since the first half-dozen couples were turned loose in Victoria, their descendants have over-run the whole island continent. So universal is the plague that it is now acknowledged that neither the pastoral nor the agricultural industry can be carried on unless runs and farms are securely protected with rabbit-proof netting. "Millions of miles" of fencing, according to the correspondent, have been erected, the cost of which can never be ascertained. The expense, however, does not end here. On some well-equipped farms, in spite of the most careful fencing, it is necessary to have trappers, diggers-out, and poison carts constantly employed in order to keep the rabbits outside the netting. On one such farm the outlay in these directions alone is, on an average, £1,200 a year. On some small farms, by simple netting in the water tanks during the dry season, as many as 10,000 rabbits have been caught and destroyed in three or four nights, while some holders of large properties state that they have killed between 150,000 and 250,000 in a year. According to one leading pastoralist, this rabbit plague is costing the Commonwealth about £10,000,000 *per annum*; for if the vermin could be exterminated, one consequence would be a great increase in the number of sheep depastured, and a consequent rise in the exports of wool, amounting, in the opinion of this authority, to not less than 500,000 bales a year.

In spite of these enormous losses no serious attempt has been made by Government to deal with the problem. No fair trial has been given to Dr. Danysz's specific. It should have been possible to set apart "a few thousand square miles of what is known as 'rabbit-riddled' country for the purpose of experimenting with the virus; but the friends of the rabbit-trapper . . . in the various legislatures have been too strong for the friends of the sheep-farmer." Public opinion, however (according to the *Economist's* correspondent) is ripening on the question, and it is certain that before long not only the Federal, but State Governments will be compelled to take decisive measures.

HOME INDUSTRIES.

The Wastage of Shipping.—"Lloyd's Register" have just published their statistical summary of vessels totally lost, condemned, &c., during 1908. The gross reduction in the effective mercantile marine of the world during the year, amounted to 800 vessels, of 809,292 tons, excluding all vessels of less than 100 tons. This compares with 868 vessels, of 851,224 tons in 1907. Of this total, the steam tonnage was 566,487 tons, the sailing 242,805 tons. The average percentage lost, &c., of British-owned ships, as recorded in "Lloyd's Register" book, shows little variation. For the quinquennial period, 1898-1902, the percentage of steamers lost was 1·93, and of sailing vessels 4·95; for the period 1903-7, 1·90 and 4·98 respectively, whilst, for 1908, the percentages were 1·82 and 4·68. It will be noticed that the percentage of sailing vessels lost is much higher than that of steamers. Strandings and kindred casualties, comprised under the term "wrecked," are much the most general cause of disaster; 43·5 per cent. of the losses of steamers, and 33·8 per cent. of the losses of sailing vessels, come under this head. The next most common termination of a vessel's career is due to condemnation, breaking up, &c., 20·4 per cent. of the steamers, and 27·8 per cent. of the sailing vessels removed from the mercantile fleets of the world being accounted for in this way. Lloyd's figures show that, large as is the absolute annual loss of vessels belonging to the British mercantile marine, it is only a small percentage of the whole, and compares favourably, anyway so far as steamships are concerned, with the loss sustained by the mercantile fleets of other leading centres. The percentage of steamers lost by France last year was 1·49, by Germany 1·20, by Norway 2·13, and by Japan 2·20, the British loss being only 1·11. We are less fortunate with sailing vessels. Of these, France lost 2·91 per cent., Germany 2·70, as compared with our 3·49 per cent. But Norway lost 4·65 per cent., Sweden 8·01 per cent., and Holland (which only owns 34,750 tons) no less than 10·63 per cent.

British Railways.—The returns of the British railways for the half-year ended June 30 show a marked recovery in the position of the leading companies. There was a further small decline in gross receipts of £264,811 or ·06 per cent., but the net earnings increased by £698,238, or 4·7 per cent. The expenses of the 19 principal English railways were reduced £963,000, or 3·3 per cent., a reduction mainly due to the fall in the price of coal, but also to some extent to real economy. The coal bill fell £549,661 or 17·6 per cent., and expenditure other than for coal was reduced nearly £400,000, mostly owing to the curtailment of goods and passenger train mileage. The reduction in freight train mileage was 5·6 for the half-year, and in passenger train mileage 1·2 per cent. The net earnings of the half-year exceeded by £698,238, or 4·7 per cent., the earnings of the corresponding six months of 1908, and the dividend earned upon the ordinary shares was at the rate of 2·96 per annum, as against 2·53 per cent. per annum for 1908. The average dividend distributed for the half-year has been at the rate of 3½ per cent. per annum, in comparison with 2·86 per cent. per annum a year ago, an increase of ·26 per cent. Thirteen out of the 19 companies increased their dividends, five maintained them, one only had to make a reduction. There is good reason to believe that the shrinkage in trade which adversely affected railway receipts in this country during the last two years is now at an end, and, indeed, appreciable expansions in earnings are already taking place. Again, methods of administration and working have improved. There has been less rash expenditure of capital, and greater avoidance of unwise competition. The outlook for the railway industry is decidedly brighter than it was.

The Coal Industry.—Whilst the demand for iron, especially for steel making, is increasing, the coal trade remains depressed. It would have been strange had it been otherwise. There has been over supply of coal. Foreign competition becomes more serious every year, and the Eight Hours Act, which bears on British coal alone, cannot fail to work for the foreigner. The exports of coal for the seven months ended July show an excess of only 180,000 tons over those for the corresponding period of 1908, which is far short of the normal rate of annual increase. But it is the home market which shows the serious shrinkage. Many factors have combined to bring about this result. During the late spell of dull trade the householder has been more careful of his coals; then gas stoves for cooking purposes are largely on the increase, and the use of electricity has its effect. The industrial consumption has been largely below normal for many months past, and the coal bills given in the half-yearly reports of the railway companies show extensive savings not all due to lower prices. The shipping depression has led to reduced consumption of coal for bunker purposes, and the threat of a strike of coal miners, not only in Scotland and Wales but in England, led to consumers laying in large stores of coal which have now to be absorbed before holders of them can be in the market again to any normal extent. But low as is the present level of prices it is higher than it would have been but for the Eight Hours Act, which has been the cause of the higher rates of wages now current.

The Cotton Crop.—Messrs. Neill Brothers have issued a memorandum on the cotton position, from which it may be inferred that in their belief the reports of bad weather have been exaggerated, but that the conditions in Texas are really serious. It is, however, too early to come to any definite conclusions as to the crop. That for 1908-9—for statistical purposes it is completed on August 31—has exceeded the totals of the two "bumper" crops of 1904-5 and 1906-7, a fact to be remembered when dealing with official estimates. According to the figures supplied by the New York Cotton Exchange the total for 1908-9 up to August 26 was 13,647,000 bales, as against 11,377,000 bales for the corresponding period of 1907-8, and 13,506,000 bales for 1906-7. In 1904-5 the total crop marketed reached 13,557,000 bales, so that 1908-9 stands well to the front. In America and on the Continent the takings by the mills are increasing; in Lancashire the recovery in trade has still to come, but margins are less.

A New Domesday Book.—The intention of the Government to value the land of the United Kingdom may serve to recall the almost forgotten Domesday Book of 1876. This compilation purported to give the proprietorship, acreage, and rental of England and Wales in the year 1874-5 exclusive of London. It had been alleged that there were only about 10,000 landowners in the country, and the return was ordered for the purpose of showing the facts, which were, according to the return, that there were in all 972,836 landed proprietors with an estimated rental of over £59,000,000, and owning in the aggregate 33,013,514 acres. Of these proprietors more than 700,000 owned less than a single acre; 121,983 owned under ten acres, while over 3,000,000 acres were owned by some 10,000 persons. It was, however, demonstrated that the return was, in some respects, misleading. For example, it was made by counties, and large owners, who owned estates in several, were counted once for each county, and in some cases figured as small proprietors. Again, the average of the large proprietors was under-estimated, as all woods, except saleable underwoods, were excluded from the return. Clergymen were often put down as the private proprietors of their own glebe lands, and no attempt was made to distinguish between rental derived from town and country property. Accepting the figures of the old Domesday and the new for the purpose of comparison, it appeared that in proportion to population the number of landowners was tenfold greater in the eleventh century than in the nineteenth.

Yarn out of Paper.—The United States Consul-General at Stockholm, in a recent report, gives some details respecting an industry about to be established in Sweden. He says that in Halmstad, Mr. Pontus Holmström is about to start a spinning mill for making yarn out of paper. Such mills already exist in Germany and France, and mention has been made of them in these Notes. So far, the manufacture of rugs and carpets seems to be the best practical use of this new paper yarn. It is stated that people in Sweden, especially in the province of Ostergötland, are already making carpets with paper welt. Narrow rolls of paper tape are used, but this, of course, is not spun.

OBITUARY.

PROFESSOR EMIL CHR. HANSEN, M.D., Ph.D. —The death occurred on August 26th of Professor E. C. Hansen, the head of the department of physiological fermentation in the laboratory of the Institute of Technical and Physiological Fermentation at Carlsberg, Copenhagen. Professor Hansen was born in 1842. He studied at the University of Copenhagen from 1871 to 1876 and in the following year entered the Carlsberg Institute. Devoting himself to independent scientific research he became known as an authority on fermentation and the inventor of a method of producing pure yeast, which is now employed almost universally in the breweries of Denmark, Norway and Sweden, and in most of the chief breweries of Germany, Holland and America. He wrote several treatises on fermentation, including "Experimental Studies on the Variation of Yeast-cells," which appeared in the "Annals of Botany," 1895. He was a Foreign Member of the Linnean Society, and in 1905 he was elected an Honorary Corresponding Member of the Royal Society of Arts.

PROCEEDINGS OF THE SOCIETY

CANTOR LECTURES.

MODERN METHODS OF ARTIFICIAL ILLUMINATION.

By Leon Gaster, A.M.I.E.E.
(Editor of the *Illuminating Engineer.*)

PART VI.*

We may now turn to another section of my lecture and refer, necessarily very briefly, to a few of the most obvious cases of lighting which deserve particularly careful study. In doing so I ask you to bear in mind what I have just said about the necessity for measuring light. This is the keynote of successful "Illuminating Engineering," for it is only by means of actual measurement, however faulty our apparatus may be, that we can preserve a permanent record of prevailing conditions of illumination. Naturally, our methods are still crude, but immense advances have been made since their practical value has been realised, and I confidently expect yet more remarkable developments in the future.

School-lighting.

I should like first to say a few words upon the subject of school-lighting. It would seem to be so obvious that good illumination bears an intimate relation to health, that the importance of lighting schools, in which children are confined at a crucial period in their physiological development, in a thoroughly satisfactory manner would be admitted at once. I am glad to say that here again the Royal Society of Arts has not been found wanting, for recommendations on this point were made by Mr. Brudenell Carter as far back as 1885 in a paper on the "Influence of Civilization on Eyesight," and again in 1898 on "The Eyesight of Children."

I have no time to quote the exhaustive data that have been accumulated to prove that the eyesight of children steadily deteriorates during school life, but I may say that they are very convincing, not only in England but possibly even to a greater extent in Germany and the United States. I may, however, refer you to an article by myself in the *Journal of the Royal Society of Arts*, of August 21st, 1908, and to a special section in the first number of the *Illuminating Engineer*, January, 1908, in which this matter is exhaustively treated.

Dr. H. Wright Thompson, oculist to the School Board of Glasgow, has found that 35 per cent. of the children in the 67 schools visited by him had more or less defective sight.

Professor Scott in the United States has quoted even higher figures, and summed up his remarks in the mournful words:—

> "Because of the lack of attention that is paid to the light actually present in the schoolroom, and because of the great difficulty in adjusting our windows and shades to the varying intensities of the external sources of light, it is not surprising that we should find in our schoolrooms conditions of light so bad during many hours of the day that the reading of ordinary printed matter without undue strain on the eyes is impossible."

We find, indeed, that it is generally admitted, as, of course, it stands to reason it would be, that defective eyesight is, at least, partially due to bad lighting in the schoolroom. The light may be insufficient in quantity and so strain the eyes of the child attempting to read. It may also come from the wrong direction, and Mr. Brudenell Carter has shown how this may affect the attitude of a child seated at his desk, and indirectly affect his growth.

In addition, it must be recognised that each portion of the schoolroom requires separate attention, and presents a separate problem.

* The Course consisted of four lectures, delivered on February 15th and 22nd, and March 1st and 8th. In re-arranging the material for publication in the *Journal*, the lecturer has preferred to divide it into six parts.

Thus the children's desks must be adequately illuminated, but special provision is necessary for the illumination of the blackboard and for the table at which the teacher is standing.

Another cause to which short sight has been attributed is the use of type that is too small for the growing child to see with comfort. This has been alluded to by Dr. H. E. J. Biss (*Illuminating Engineer*, Vol. I, p. 190), and it is interesting to note that, by the advice of Mr. Brudenell Carter, *The Times* have recently decided to alter the nature of their smaller type.

The importance of this question to the nation will be understood from the fact that there are over 1,000,000 children in the schools of London alone. It is interesting to recall that Mr. Brudenell Carter, as far back as 1885, approached the School Board of London, and tried to induce them to organise periodical testing of the eyes of their children.

That Mr. Carter had ample grounds for urging this improvement will be understood from the decisive nature of the results of the tests of the German Professor Cohn, who in 1865 examined the eyes of about 10,000 school children and found that 1,630 of these had eyes of faulty shape, 1,072 being short-sighted, 139 flat eyed, 23 suffering from astigmatism, and 396 from the results of previous diseases. In addition, Mr. Carter's friend, Mr. Adams Frost, had examined a Board school in the South of London and found that 73 children out of 267, or rather more than one-fourth, suffered from defective vision. It was rational to conclude, therefore, that the possibility of equally bad conditions prevailing in other schools ought at least to be examined. On this occasion, as we have since had ample reason to regret, this recommendation was not complied with, but at the present day our views are more enlightened, and only last year it became obligatory for the London County Council for the first time to undertake periodical tests of this description.

But I feel constrained to point out that tests of eyesight alone are insufficient unless accompanied by some study of the conditions of illumination. It is no use studying a disease without also taking account of the conditions by which it was produced. In this connection it is satisfactory to note that Dr. Kerr, medical officer to the London County Council, made special reference to this matter in his report in 1908. I may quote the following words :—

"A normal person of middle-age will distinguish characters on paper in a poor light with greater readiness than a child, because the characters are more familiar to the adult and so much more easily recognised. Conversely, a child requires a better light to learn to read by than does an adult, to whom reading is second nature. From a large number of experiments, the least illumination permissible on the school desk of a child has been found to be equal to 10 candle-metres (*i.e.*, roughly 1 foot-candle)."

Dr. Kerr then studied the illumination in 165 schools, and found that the artificial illumination of about 20 per cent. was classed as only "fair," while 18 were considered "bad;" very similar figures were quoted of the daylight illumination.

In the report which has just been issued for the subsequent year stress is again laid on the part played by good illumination. Thus Dr. Woodcock points out that, apart from eye-troubles, nervous habits such as squinting, twitching of the eyebrows, &c., giving rise to a strained expression, are often the direct result of the close attention and effort involved in certain kinds of work (such as sewing) which impose a tax on the eyes. For instance, reference is made to a class of 28 children who were hemming in a poorly-lighted room. A few minutes after work had commenced ten were squinting, eleven knitting their eyebrows, two standing up to sew, and half-way through the hour four children exhibited nervous defects. "Artificial light in schools" this observer goes on to remark "is practically always insufficient for this work" (*i.e.* fine work involving matching of colours and texture with precision). "From October to March," she says further, "no needlework should be allowed after 3 p.m., and during November 15th to February 15th no needlework should be permitted in the afternoon at all."

In this report Dr. Kerr again gives some figures relating to the conditions of illumination in various schools; they are as follows:—

QUALITY OF LIGHTING.

April 1st, 1907, to March 31st, 1908.

Non-Provided Schools—		
Good	57	65 per cent. approx.
Fair	10	11 ,, ,,
Bad	21	24 ,, ,,
Council Schools—		
Good	191	73 per cent. approx.
Fair	16	6 ,, ,,
Bad	52	14 ,, ,,

April 1st to December 31st, 1908.

Non-Provided Schools—		
Good	18	72 per cent. approx.
Fair	3	12 ,, ,,
Bad	4	16 ,, ,,

Council Schools—

Good........	237	81 per cent. approx.
Fair	23	8 ,, ,,
Bad	33	11 ,, ,,

Now, when the appointed authorities take the view explained above, it is sufficient to justify the contention that the study of the illumination in schools is a matter that deserves very careful attention indeed.

Factory and Barrack Lighting.

While dealing with the hygienic aspects of illumination, I may refer to the lighting of factories and barracks. Here again, although we are dealing mainly with adults, instead of children, we have a case of large numbers of people constantly at work under more or less stereotyped conditions. Think how many soldiers are constantly confined in barracks in this country.

I was given to understand that the War Office authorities were paying great attention to this subject, being desirous of adopting some definite plan for supervising the lighting in these cases, so as to render it in everyway most efficient.

In the same way, it would seem to be a truism to say that good illumination in factories is not only absolutely essential to the work-people, but expedient from the point of view of the employer. Good illumination, as I have tried to show, is not a luxury but a necessity, and therefore ought to be insisted upon every whit as keenly as the provision for adequate sanitation and ventilation, which, by the way, have only become the subject of Government inspection and recommendation (and in extreme cases even of prosecution) very recently. Why should an employer who confines his employees in a stuffy room be treated more severely than one who ruins their eyesight by grudging the necessary attention to lighting?

What may be pointed out in addition is that, even from the standpoint of the employer, it is folly to neglect this point. In the case of almost all skilled labour it is quite certain that the expense of bringing the lighting up to the standard is but a trifle in comparison with the amount that would be saved by the improvement both in quality and output of work; indeed, in many cases it is safe to say that such improvements as are needed would not really entail any greater running expenses, but only the exercise of a little forethought in using the light provided so as to help the workman instead of proving a nuisance to him.

But, in addition, there are obvious general grounds for dwelling on this point. Anyone who has been obliged to live for any length of time in dingy and badly lighted rooms knows the depressing effect of such surroundings.

Mr. Patchell, in his presidential address to the Association of the Engineers in Charge in 1908, remarked:—

"Good lighting is conducive to economy in both engine and boiler rooms, as plant in a badly lighted room never gets properly looked after or cleaned. Why should it? It is no credit to the cleaner if it cannot be seen. Dirt is about the worst disease a plant can suffer from, as it invariably means neglect of small indications and warnings, timely attention to which would prevent the otherwise inevitable break-down. Not only is the plant better cared for, but men all work better in cheerful surroundings, and lose less time through sickness."

Another point on which stress may be laid is that a very close connection undoubtedly exists between the number of accidents that occur in works, and the condition of the lighting. Naturally, it is easier for an employee to allow a limb to stray into machinery which, in a dingy ill-lighted room, is blurred and indistinct. In addition, the incorrect placing of light sources, and the resultant throwing of inconvenient shadows by tools is just as likely to be responsible for an error of judgment on the part of an operator engaged in a delicate piece of work.

At the present moment this matter is of particular interest in view of the Commission that has recently been appointed to consider causes of accidents in factories and workshops, and I should like to urge that no such inquiry can be considered complete that does not take into account the part doubtless played by defective illumination in causing accidents of this nature.

The report of the Chief Inspector of Factories for the year 1908 contains a number of pertinent comments on the effect of the lighting conditions on the health and well-being of operatives. It is gratifying to find one of the inspectors reporting that great advances have been made in the artificial lighting of factories; the same observer, however, remarks that the fact is not generally appreciated that the daylight-illumination requires corresponding care. A very striking case is that of laundries. It would seem fairly evident that where cleanliness is the great consideration, only the very best illumination can be deemed sufficient, and it is not surprising to find one of the inspectors, Miss

Patterson, drawing attention to the effect of "crowding machinery into ill-lighted corners."

But, perhaps, the most interesting comment is that of Miss Squire, who referred to the defective illumination in certain Yorkshire textile factories, and the results of the trying work in a poor light on the eyesight of employees. Sometimes the suggestions of the inspectors recommending were welcomed and acted upon. "Sometimes, however," she says, "we are met with indifference or reluctance to spend money on this condition for healthy working, *and we have no statutory provision to rely upon.*"

The need of more definite recommendations regarding illumination, therefore, is now beginning to be felt. Reference may, in this connection, be made to a very interesting report of the Conseil d'Hygiène de la Seine in Paris on the subject of factory-lighting. As a communication from a municipal body this forms a somewhat important precedent. The report contains abstracts from the regulations of the chief European countries.

While not proposing any immediate drastic regulations the report emphatically endorses the wisdom of keeping all bright lights out of the field of view of workers and also advises that walls should be light in tint and have good reflecting qualities. It is interesting to observe that the only country, apparently, that prescribes definite minimum illumination is Holland, where an intensity of 10 to 15 bougie-metres on the work is specified (1 to 1·5 foot-candles approximately).

Lighting of Hospitals, Libraries, Churches, Etc.

Under this heading I may include a number of miscellaneous cases of lighting, all of which are of very great importance, but which, unfortunately, would require a lecture to themselves if treated fully. I may first point out the obvious necessity of lighting a *hospital*, where people in an invalid and depressed condition are confined with special care.

It is scarcely necessary to point out that people, under such circumstances are specially susceptible to the effect of unsatisfactory conditions of illumination, and trifling defects in the lighting arrangements, which a healthy individual might ignore, assume much greater importance in the case of people who are seriously unwell and possibly feverish. Anything in the least inclined to suggest a glare is most objectionable, and flickering and unsteady lights are particularly undesirable. One may also point out that the lighting of a ward in a hospital where patients in a convalescent stage are confined is probably governed by conditions quite distinct in many respects from those that should prevail in a room in which patients are seriously ill.

The daylight illumination provided is perhaps of special consequence, stress being laid by many in the medical profession on the part often played by sunlight in promoting a patient's recovery. For instance, at the request of the Westminster Hospital, an interim injunction was recently granted restricting the height of the adjacent new Wesleyan Memorial Hall now being built by the trustees of the Wesleyan Twentieth Century Fund. It was contended by the medical authorities that the proposed plan would interfere with the access of light to one portion of the hospital, and that the recovery of patients would be appreciably retarded thereby.

The necessity of paying careful attention to the light in *libraries*, where people use their eyes very severely, must also be borne in mind. This last matter is the more urgent because the people who use libraries in the evening by artificial light are, as a rule, earnest students, the class of people who derive most benefit from libraries, and who, therefore, deserve the best artificial illumination that can be provided in order to facilitate their strenuous work.

Both libraries and hospitals frequently constitute an expense to the general public, who have a right to see that the best value is got for their money. The lighting of a number of such public buildings may in the aggregate amount to a considerable sum, and therefore it is only just that care should be taken not only to get efficient results, but also to exercise due economy.

A recently-issued report of the "Committee on Machinery and Engineering Staffs at Poor-law Institutions," which deals incidentally with the lighting conditions, well illustrates this point. The published figures for the lighting in question show remarkable variations, and the conclusion is drawn that greater care should be exercised in the control of the expenditure of gas and electricity than at present. Yet it must be recalled that many different varieties of buildings, which serve very distinct purposes, are grouped under this head, and it is, therefore, very difficult to draw any valid conclusion without knowing fuller details of the conditions in each case. One point may, however, be emphasised. It would

well repay the authorities in such cases to obtain the advice of a competent expert when the original lighting scheme of a new building is under consideration. Experts called in at a later stage may, indeed, be able to effect a considerable saving; yet, when once the installation is complete, any modification must be in the nature of a compromise, and it is rarely possible to secure as efficient results as might have followed the original adoption of a carefully thought-out plan.

In this connection I should like to mention the work of Mr. L. B. Marks, a well-known illuminating engineer in the United States, and the first President of the Illuminating Engineering Society, who has recently undertaken and described the lighting of the Carnegie libraries in New York, in a specially careful manner (*Illuminating Engineer*, Vol. I., 1908, page 921). Here, again, I should like to point out the inconsistency of paying for the collection of expensive books, sometimes unique and unreplaceable, housing them in costly buildings, and then providing a system of illumination that makes reading more than a weariness of the flesh.

And next, a few words may be said upon the lighting of churches and public buildings of architectural distinction. In such cases, economy and illuminating efficiency, in the technical sense, are often subservient to artistic effects. But once more we must remember that it is only through the eye, and through the illumination provided, whether daylight or artificial, that the interiors of such buildings are visible at all. Therefore it is surely worthy of consideration to scheme out the lighting very carefully, and to consider exactly what the sources used have or have not to do. This is a matter I commend to the study of architects, who are now coming to take a keener interest in questions of illumination.

Fig. 83.

Second Floor, Carnegie Library in New York. (L. B. Marks, Second Annual Convention of the Illuminating Engineering Society in the United States, 1908.)

The lighting of such national buildings as Westminster Abbey surely deserves very careful consideration indeed, and when we remember that they frequently fulfil several distinct purposes the choice of an effective method of illumination becomes correspondingly difficult. For instance, Westminster Abbey serves primarily as a religious building, but, being the treasury in which so many national monuments, &c., are stored, also partakes of the nature of a museum. And the lighting of our museums, if attempted artificially at all, surely demands the greatest care we can give it. For the exhibits can only make their appeal through the eye, and the eye only becomes aware of their

existence by the aid of light. Naturally therefore one would suppose that the method of lighting specimens so as to show off their chief points to the best advantage would be very carefully thought out and as near as possible ideal for the purpose; it is doubtful whether this can often be said to be the case.

Fixture Design.

This, again, is a very wide subject into which I cannot enter in detail. It will, however, be readily appreciated from what has been said already, that fixture-design offers great opportunities to the man who has not only a knowledge of the details of the best methods of distributing light efficiently, but also a genuine appreciation of artistic principles. There seems little doubt that a great many of the types of fixtures in general use at the present day leave something to be desired both from the æsthetic and practical standpoints, though great improvements have recently been made; in the United States in particular, the recent formation of the Illuminating Engineering Society has given a great impetus to the scientific design of fixtures from the standpoint of practical efficiency. It is, however, often interesting to observe the care which was bestowed on the artistic design of sources of illumination in the past, which were certainly very primitive regarded from the practical standpoint as illuminating apparatus, but were not infrequently distinctly effective as ornaments.

It is also hardly necessary to dwell upon the importance of a knowledge of the particular varieties of fittings which are best adapted for use in certain interiors; the illuminating engineer, engaged on such work, needs to possess a considerable knowledge of art and architecture in order to contrive arrangements in harmony with the existing scheme of decoration.

An interesting point has been raised in a recent number of *The Builder*. The author criticises many of the existing electric light standards in the streets of London, and points out how illuminating apparatus of this kind, while at night mainly essential for the purpose of producing light, ought to be decorative by day when its main function is in abeyance. The engineer would often be grateful for guidance on the æsthetic principles involved in this question. Certainly the style of lamp-posts lining a street can do much to make or mar its architectural appearance, and ought to be in harmony with the style of buildings or surroundings.

Fig. 84.

Roof Reading Room, Carnegie Library in New York. (L. B. Marks, Second Annual Convention of the Illuminating Engineering Society in the United States, 1908.)

STREET LIGHTING.

The subject of street lighting received some attention in Part III. of these lectures (see p. 805), but this occasion may be taken of emphasising a few of the most important points in connection with the matter. Since the delivery of these lectures the writer has had an opportunity of visiting many of the chief continental cities and conversing with the chief engineers responsible for the street lighting, both gas and electric, therein. Many differences of opinion were met with but it was invariably agreed that the points in dispute among experts could be largely cleared up if only the different authorities interested could be got together to discuss the matter and determine in what good street lighting really consists. At present the criteria are extremely vague, what is regarded as eminently satisfactory in one city being tabooed in another.

Unfortunately it cannot be said that any really adequate effort has yet been made to distinguish between the purely local conditions which so often influence decisions on this matter and the general principles which are applicable to most cities, It is frequently supposed by those who do not appreciate the part which local conditions inevitably play in deciding such questions that because some city, Berlin for example, adopts incandescent high-pressure gas lighting after protracted tests comparing the results of this method with those obtainable by electric lighting, therefore the relative merits of both methods have been settled once and for all and that any other town in doubt as to the method of lighting to be adopted can profit by their lesson and do likewise.

In reality the decision of the authorities may be mainly influenced by facts quite outside the tests in question. In Berlin, for example, the gas-plant is owned by the municipality while the electricity supply company pay handsomely for the privilege of undertaking electric lighting. Now vast extensions to the present gas-generating plant have recently been made at Tegel near Berlin, and the authorities must naturally look to street lighting as a main outlet for the gas generated. It may in fact be said that every city has to find out for itself which method of lighting best meets local conditions.

Yet there is no reason why they should not derive useful information from properly organised experiments of other cities relating to matters which really can be settled by scientific experiment. But these experiments must be undertaken with a clear and definite idea of what it is desired to find out, and the results derived from them must be presented in such a way as to be free from confusion with the local influences referred to. And in order to be reliable such tests ought to be undertaken by an impartial and expert authority whose decision would carry weight. The writer long ago advocated the establishment of a central testing department for the purpose of undertaking genuine research into street lighting problems. The tests would be more valuable, even on the present lines, where they undertaken by representatives of gas and electric lighting conjointly and on a pre-arranged common plan. At present, what frequently happens is that a series of tests are undertaken by an expert in electric lighting, and another series, undertaken on quite different assumptions and under quite different conditions by a representative of gas lighting. Subsequently the results (being really not strictly comparable) are found to be at variance, and those connected with each system profess to distrust the tests of the other and to believe that he has contrived a method of experiment which is specially favourable to his own illuminant. Were the experiments carried out by both representatives simultaneously, as explained above, much useless subsequent recrimination might be spared; and there would be more probability of our being able to draw some useful conclusions.

There is in some quarters an impression that street lighting is a simple matter which can be readily judged by ocular demonstration before a body of men having no technical knowledge of the matter. Apart from its other drawbacks, however, it is at least obvious that such methods must give rise to hopeless difference of opinion, and that the possibilities of such differences are accentuated by the fact that an opinion so based cannot be substantiated by reference to any record which would guarantee that the conditions existing when the impression was gained would be maintained subsequently. When our knowledge of the lighting in a street is based on photometric tests we can, at any subsequent period, repeat these tests in order to ascertain whether any change in the conditions has occurred. But when we merely depend on our recollection of what the lighting looked like on some past occasion, how is it possible to justify an impression that the light has deteriorated?

In addition, it is safe to say that ordinary people base their views on the lighting of a

street on very different data. Many people, for instance, will be found to judge far more by the apparent brightness of the sources themselves than by the available illumination which they shed upon the roads and pavement. Nor is it to be expected that a man who has not really studied the problem can, by a mere visual impression, unsupported by any means of measurement, determine which of two alternative systems of lighting is best fitted to suit the complex demands of traffic, the needs of pedestrians, artistic appearance, and the other factors which have to be duly weighed in this matter.

In short, we need to form more definite views regarding what the object of street lighting should be, and better methods of expressing and measuring the requisite conditions. For this purpose photometry, as we now know it, is admittedly capable of improvement, and may in the future be supplemented by other tests. But it is certainly capable of preserving a record and yielding much valuable information unobtainable at present by any other means.

Shopwindow Lighting.

A word or two may be said on this interesting subject. There is, perhaps, scarcely any field where the principles of illuminating engineering can be more profitably employed. It is no exaggeration to say that one still cannot walk the streets of London, or indeed any city, without constantly meeting examples of light, not only unwisely, but actually uselessly employed.

We have seen previously how the interposition of a bright light causes the pupil-aperture and retina of the eye to react in such a manner that objects of a darker hue in the background become difficult to see, and how the eye is injuriously affected by continual exposure to glaring lights. Yet one frequently sees naked filaments placed in the window between

Fig. 85.

Shop Window, Richmond, U.S.A. Lighted by Gas; Night View (Welsbach Co.).

the eye of the observer and the goods he is intended to observe by their light; frequently, too, the pedestrian is dazzled by a lavish use of intensely bright flame arc lamps, hung well within his field of vision round a shop-window; such lamps if not properly located are also a menace to traffic on account of their inconvenience to drivers. It is satisfactory to observe that regulations have recently been introduced in the City of London, forbidding the use of such lamps unscreened towards the roadway.

Such malpractices ignore the wise motto, "Light on the object, not in the eye." To be successful, any method of shopwindow lighting must be at least comfortable to the eyes. A window may well be likened to a miniature stage. The use of bright lights has been defended on the ground that it is necessary to be lavish in this respect to attract custom. Excessive glare may, indeed, attract the eye involuntarily, but it is questionable whether anything is gained thereby, as the observer naturally tends to avert his gaze from anything actually distressing.

The most successful methods of shop lighting seem to be those in which the lessons of the stage are taken to heart, abundant light being shed upon the goods while the actual sources themselves are screened from the eye of the observer. Some examples of this method are shown in Figs. 85 and 86.

In Fig. 86 it will be observed that the same lights which, concealed, illuminate the contents of the window, are also utilised to illuminate the sign "Cigars"; this is a device which is now becoming very popular.

Fig. 86.

Tobacco Shop in Washington, U.S.A, Lighted by Gas. Night View.

In Fig. 88 will be seen a means of applying this method by the aid of flame arc lamps, which are placed above a diffusing glass surface over the goods, and can be drawn aside to be attended to, when necessary, as shown in the illustration.

Apart from these obvious rules of good lighting there are, of course, endless possibilities in the direction of achieving special effects by the use of light, and these afford great scope for artistic treatment. In some of the best shops arrangements are made enabling several alternate methods of lighting to be used, a change in the contents of the window

being accompanied by a change to the method of illumination best adapted to display them to the best advantage.

In this connection it may be of interest to point out that a change in the motives of window-display, first perceived in the United States, seems to have been making itself felt perhaps especially in the United States, it is becoming felt a tasteful shop-window should be mainly devoted to novel and specially interesting goods, so that the passers-by may come to regard its contents, not as a catalogue, but as a summary of the most recent developments; this leads him to look to the window

FIG. 87.

SHOP WINDOW OF CARPET STORE ILLUMINATED BY MEANS OF REFLEX GASLIGHTS. (Welsbach Co.)

also in this country of late. In many shops the window display is regarded mainly as an inventory, as complete as possible, of the goods kept in stock. The customer is expected to make up his mind what he wants by inspection of the window, enter, and ask for this article. This naturally involves crowding the windows and makes effective lighting methods difficult to achieve. Now, however, for novelties and not to pass it by, assuming by the force of habit that it contained nothing new. He would, therefore, no longer be expected to make up his mind as to his requirements before entering, but would be induced to do so whilst yet undecided as to whether he meant to purchase, and would be prepared to entertain suggestions and assistance from the shopman on the subject of what he needs. It

is possible that this newer attitude towards window-dressing may have a beneficial influence on the methods of lighting employed.

FIG. 88.

STAGE LIGHTING.

There is, perhaps, no subject which presents better opportunities for successful co-operation between the illuminating engineer, with a knowledge of the best means of producing and using light, and the artist with his trained perception of what is most beautiful, than that of stage lighting.

It is not only that the general method of illumination employed in a theatre is of very vital importance; in any entertainment in which an appeal is made to the eye it is, of course, essential that there should be nothing distressing or distracting in the illumination provided for the benefit of the audience. But the success of many theatrical pieces and operas is so closely connected with the impression received through the eyes, that the illumination of the stage itself must require not only specialised knowledge of technical details, but also, in an exceptional degree, fine perceptions and artistic sensibility. In operas, for instance, one can readily understand that the scheme of lighting should produce an effect parallel to and in harmony with that produced by the music. The most artistic scenery, again, would be diminished in effectiveness by a choice of a method of lighting which interfered with the proper colour relations. There are also numberless theatrical devices, such as the simulation of flowing molten metal, the production of sparks between clashing swords, apparitions, and so forth which offer great scope to the ingenuity of the engineer in charge of the lighting of the stage.

While it may be justly said that the arrangements at our best theatres often reflect very great credit on those responsible for the stage lighting arrangements, it seems quite reasonable to suppose that in this subject special benefit might follow a closer co-operation between the illuminating engineer, the artist, and the other specialists whose views have a more or less direct bearing on the subject.

LIGHTHOUSE ILLUMINATION, &c.

The provision of proper means of illumination round sea coasts, for the indication of waterways and channels, and for purposes of navigation generally, is, of course, a matter of international importance, and one on which the concerted action of different nations is particularly to be desired. The wideness of the subject, which demands peculiar expert knowledge, is well illustrated by the annual report issued by the Lighthouse Board of the United States.

I cannot discuss this important subject in any detail on this occasion. It may, however, be said that it is one which the illuminating engineer should find of special interest, and in connection with which he may, in the future, render valuable service, because it involves the consideration of the merits of the different illuminants in an impartial manner.

Those who wish for fuller information may be recommended to study the report of the Royal Commission, which was issued last year, relating to the lighting of the shores of Great Britain and Ireland.

SOME PHYSIOLOGICAL EFFECTS OF DIFFERENT QUALITIES OF LIGHT.

I may next make a few remarks upon another feature of artificial lights of the

present day which seem to require study. I have already drawn your attention to the difference in the colour of light yielded by modern sources. Now we have no precedent to enable us to determine what may be the effect of very peculiar coloured light in any quantity on the eye, though there is scientific work on record which suggests that visible light from different parts of the spectrum produces diverse physiological effects. Therefore one would certainly recommend that we should be cautious in seeking to work for long hours under any peculiar variety of light. Professor Burch, in the work previously referred to, has dwelt upon the disturbances of colour vision which may be called into play through intense stimulation of the eye by monochromatic light, and it is therefore legitimate to suggest that prolonged working under light of one colour might eventually affect the eyes in some such way.

Meantime it is interesting to observe that there seems to exist some prejudice in favour of light of a more or less golden colour as compared with the whiter tinge of the most recent illuminants. The explanation of this preference offers very debatable ground for discussion. Some authorities have maintained that light from the red end of the spectrum has an actual stimulating physiological effect, while blue and green light, on the other hand, are depressing. Others have sought to show that a preference for yellowish light is merely a matter of association. From the early camp fires onwards our sources of light and heat have come to be associated with red and yellow shades of colour, and we involuntarily connect this view with the warmth and brightness within as opposed to the blue shades of twilight and the coldness without.

It seems quite conceivable that the radiation from the different portions of the spectrum, which we are accustomed to consider mainly in connection with its illuminating capacity, may also be responsible for deep-seated physiological effects and influence our health and well-being to a very considerable extent. And, leaving out of account for the moment the possible special effects of visible light of different colours, we must also remember that our present illuminants radiate a wide range of invisible waves, which are not detected by our eyes as light but which may, nevertheless, not be without influence upon our physiological condition. Recently a number of facts have been discovered about the behaviour of the so-called actinic or ultra-violet rays (beyond the violet in the visible spectrum), which have led physiologists and physicists to attach some importance to their presence, to some extent, in all illuminants. With this matter we shall deal in some detail later.

For the moment, however, let us turn our attention to what is known regarding the quality of radiation from different illuminants, and the manner in which the energy is distributed throughout the visible and invisible spectrum. This quality, we shall find, exerts a very material influence on the efficiency of light-production of the different sources.

The Distribution of Energy in the Spectra of Illuminants and the Efficiency of Light-Production.

In what follows, therefore, I wish to proceed to consider some of the scientific theories of light production. It has long been believed that the majority of sources of light, considered from the scientific standpoint, are hopelessly inefficient, producing but a small fraction of the energy supplied to them in the form of light. For instance, the percentage of the energy developed by electric glow-lamps in a visible form has been variously stated as being only about from 1 to 10 per cent., all the rest being produced as heat or other forms of energy which are non-luminous.

As explained in my first lecture, the majority of our illuminants consist of incandescent solids. We merely heat up a solid body until, amid the jumble of vibrations that occur, we find a few sufficiently rapid to emit light. One interesting quality of incandescent solids is illustrated by Kirchoff's law, which states that every body emits only that radiation which it can absorb. According to this view a *truly black body*, which absorbs all the energy falling upon it, can naturally emit all forms of energy. Most of our incandescent solids resemble a black body somewhat closely, and therefore the curves describing the quality of radiation obtained from such bodies at different temperatures, according to Lummer and Pringsheim, are of considerable interest. Fig. 89, which is taken from a recent article by Dr. Drysdale in the *Illuminating Engineer*, shows these curves. I cannot, on this occasion, enter into the methods by the aid of which the energy in any part of the spectrum can be measured. Most of these methods depend upon the reception and absorption of such energy upon a blackened surface; the rise in temperature of this surface may be taken as a measure of the energy impinging upon it and

Luminous Efficiencies of Various Sources (Drysdale, the *Illuminating Engineer*, June, 1908).

Source.	Observer.	Date.	Method.	Total Efficiency. Per cent.	Radiant Efficiency. Per cent.

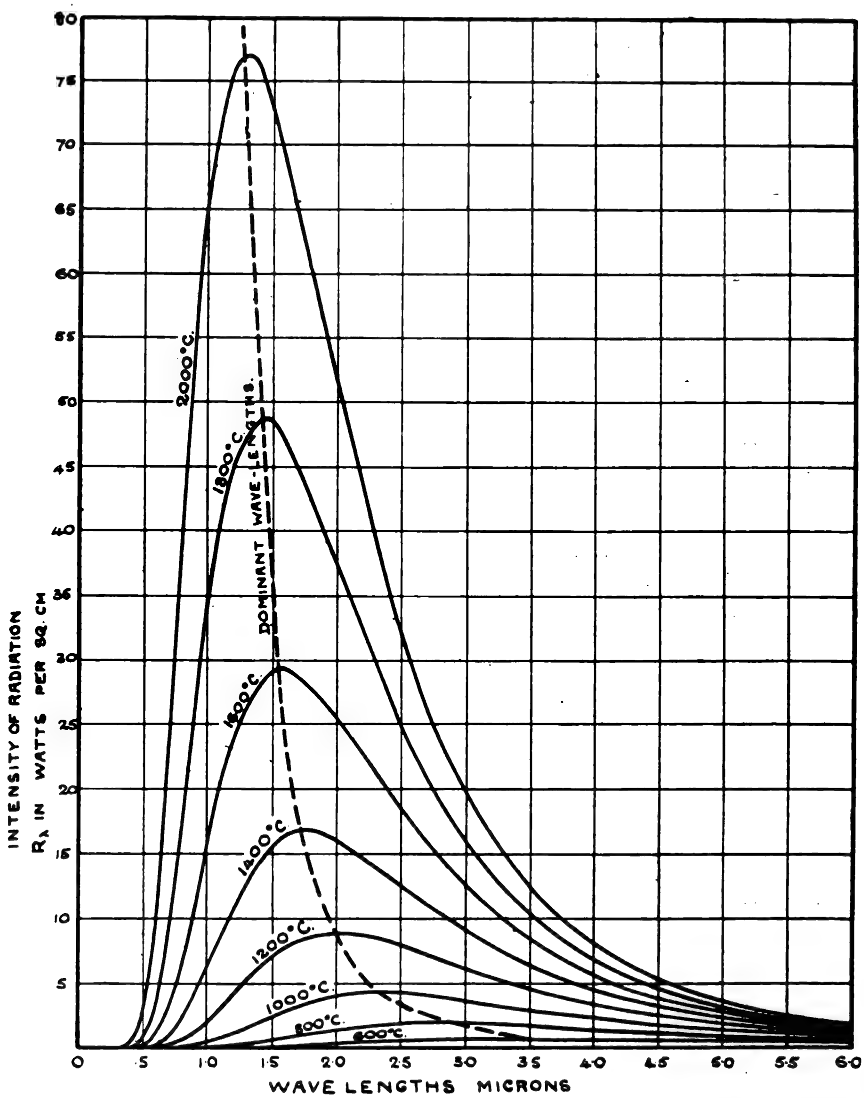
is recorded by suitable means, usually thermo-electric. You will, however, see that as the temperature increases the percentage of the radiation lying within the visible spectrum increases also very markedly, and hence our efficiency increases; Dr. Drysdale has recently calculated that the luminous efficiency even of an incandescent black body might attain 50 per cent. at the enormous temperature of 7,000°. Naturally, we can hardly hope to pproach this temperature in any of our ordinary illuminants, and, therefore, the efficiency as a light-producer is usually very low. The curves in Fig. 90, for instance, show the distribution of radiation in the case of a flame, the arc light, and the sun, as determined by the American physicist, Dr. S. P. Langley, and recently presented by Dr. Drysdale in the articles referred to above. Only in the case of the sun does the maximum fall within the visible spectrum; the majority of energy even then is waste, as far as luminous impression

FIG. 89.



CURVES OF RADIATION FOR BLOCK BODY.
(*See* Drysdale, *Illuminating Engineer*, London, Vol. II., 1909, p. 231.)

is concerned. It will, however, be perceived that in the case of the firefly a very different condition of things occurs, all the energy being concentrated within the visible range.

The mention of phosphorescence leads me to speak of an alternative method of increasing efficiency besides increasing the temperature of a body. Instead of employing the confused

Energy Distribution in Firefly Spectrum.

LANGLEY'S CURVES OF RADIATION. (Drysdale, *Illuminating Engineer*, London, Vol. II., Jan. 1909.)

This has been suggested by some observers to be a curious property of fluorescent and phosphorescent substances, and leads us to hope that a really efficient light might be produced by this means in the future.

vibration of an incandescent solid, in which the whole mass vibrates as a whole, we may employ the free natural vibrations of a phosphorescent or "luminescent" substance.

Theoretically, as we have seen, it might be

considered with some reason that the ideal illuminant would be one which produced a curve of spectral intensity identical with that of average daylight, but entirely confined to the visible range of vibration. Could we, therefore, discover a substance the natural vibration of which corresponded exactly to this state of things we should consider ourselves on the way towards solving our problem. Even the above assumption, however, may perhaps ultimately be found to require modification.

From one point of view an illuminant which produces all the rays just as they exist in the visible spectrum of daylight, and these only, might be said to have an efficiency of 100 per cent. But since the luminous efficiency of different parts of the spectrum itself differs very much, the maximum effect being, according to some authorities, produced in the yellow-green, it might be possible, by sacrificing colour, to receive yet greater efficiency. For certain purposes, in a lighthouse, for instance, it is obvious that correct colour appearance is immaterial; *brightness* is what we chiefly want. Therefore one might recommend the attempt thus to specialise in the most efficient light for certain special purposes.

Yet even this recommendation wants modification, because it is evident that all such statements are affected by the physiological peculiarities of the eye. Without entering further into this question it may be said that according to some authorities the behaviour of the eye seems to be profoundly altered when the illumination is very low; therefore the light, which is most efficient under ordinary circumstances, may not be the most serviceable under these altered conditions.

Many investigators have sought to determine what would be the theoretical efficiency possible in the case of an approximately white light, supposing that we were able to exclude all the wasteful non-luminous radiation and to produce only luminons energy. According to Dr. C. V. Drysdale, for instance ("Proc. Roy. Soc.," Vol. 80, 1907), it should be possible theoretically to obtain a white source running at only 0·08 watts per candle, and a monochromatic yellow-green source consuming only 0·0598 watts per candle. This, of course, would be a great advance on the best of our present metallic filament electric lamps which probably cannot, as yet, be commercially used at less than about 1 watt per candle.

Yet it must be said that different observers have obtained very divergent numerical results on this question as yet. The theoretical efficiencies possible, on the assumption that only light energy is produced, according to Lux, Wedding, and others, are widely different, in many cases, from the figures mentioned above; we should probably act wisely in postponing judgment on this point until more complete data are available. Very possibly these values will be found to be largely dependent on the physiological conditions of the eye. For instance, Mr. J. S. Dow has suggested that, on account of the physiological phenomena alluded to above, the values of the maximum efficiency, for light of different colours, may be found to be very different at high and low illuminations, and may also be affected by the region of the retina in the eye used in making the determinations (*Electrical World*, N.Y., Dec. 12th, 1908).

Unfortunately, most luminescent substances at present display inclinations to radiate in an irregular manner, and to produce light of certain wave lengths only; thus a source like the mercury vapour lamp, or the flame arc, usually radiates very strongly in certain parts of the spectrum, while other portions are correspondingly weak. In the mercury light, for example, the red rays are entirely absent. Many flame arcs again owe their efficiency partly to the production of a very strong peak in the yellow, where the sensitiveness of the eye to visible light is believed to be a maximum.

Naturally, such sources as these cause considerable colour distortion in the coloured materials on which they impinge; even sources, however, which yield a continuous spectrum, differ very much in the strength of the radiation in different parts, and therefore differ in the appearance of coloured objects to which they give rise.

The Table obtained by G. H. Stickney (Illum. Eng. Soc. 1908) illustrates the appearance of objects of various colours seen under the light of various illuminants.

It may be suggested that a Table of this kind might well be of considerable interest to decorators, architects, and others engaged in problems connected with colour-effects in interiors. As was pointed out in Part V., the choice of the colour of wall-papers, &c., in an interior is a matter which has a very considerable effect upon the conditions of illumination, and should not be settled quite apart from the spectrum of the illuminant to be used. It is also not so easy invariably to foretell how an object of some particular shade may appear

when viewed by means of a different illuminant from that under which it is first seen and purchased; and, as mentioned previously, even the surroundings are not without influence in determining the colour of objects seen in an interior.

There is also a need for some form of instrument which can readily be applied to compare the spectra of different illuminants, and in this connection the "Ives colorimeter," which was described at the second annual convention of the Illuminating Engineering Society in the United States last year, is of considerable interest.

COLOUR VALUES OF ARTIFICIAL ILLUMINANTS.—By G. H. Stickney.

ULTRA-VIOLET LIGHT AND THE PHYSIOLOGICAL EFFECTS PRODUCED BY IT.

Apart from the effect of visible light, however—and it has been shown that artificial illuminants differ very markedly in this respect—the distribution of energy in the spectrum of illuminants varies yet more greatly, as the curve exhibited in Fig. 90 very clearly illustrates. Therefore we are naturally inclined to wonder what effect, if any, such changes in the character of the light we live under might have upon us.

This leads me to speak of a very interesting question that has recently been the subject of much discussion, namely, the effect on sight of the invisible rays of very short wave length beyond the violet in the spectrum of artificial illuminants. We have seen how, as the temperature of an incandescent solid body increases, the maximum of the curve of radiation is shifted forward towards the blue in the spectrum, so that the percentage of ultra-violet energy is distinctly increased. Now these rays appear to exert very marked physiological and chemical actions, and it has therefore been the subject of consideration how far the tendency towards accentuating them might be injurious.

Apart from this tendency of a part of incandescent solid substances, we have now at our disposal sources such as some types of arc lamps, and the quartz tube mercury vapour lamp, which are particularly rich in such radiation, and are, therefore, claimed to be specially serviceable for particular purposes, such as the destruction of bacteria, the treatment of leather, and for photographic and medical purposes. One very interesting example of the use of the Uviol lamp I may mention in passing. It is now believed that the fading of colours is largely due to the effect of ultra-violet light and the chemical action of rays of short wave length in the spectrum of the sun. Carpet manufacturers in the north of Germany used formerly to have to send their goods down south, where sunshine was more abundant, in order to test the permanence of their colours. Now, however, that a source so rich in ultra-violet light is available, they can test goods by the light of this lamp in a mere fraction of the time which was formerly necessary, and independently of climatic conditions.

The percentage of ultra-violet energy in ordinary incandescent illuminating agents is believed to be relatively small, possibly not more than a fraction of a per cent., but, on the other hand, it has been suggested that as much as 30 per cent. of the total energy radiated from the mercury quartz tube lamp is available in this form. Naturally, therefore, special precautions have to be taken to avoid such sources having an injurious action on the eyes of anyone using them.

That a small change in the quality of radiation may eventually cause the eyes inconvenience is shown by the experiences of travellers in the snowy regions and at high altitudes where the atmosphere is not sufficiently dense to absorb the ultra-violet rays in daylight so effectively as on the horizon. Snow blindness, and the tanning of the skin are well-known symptoms at high altitudes, which many observers have attributed to the effect of ultra-violet rays.

A considerable amount of work has been done on this subject by Drs. Schanz and Stockhausen, in Germany. These observers have suggested that artificial light is invariably more wearisome to the eye than daylight, and regard the tendency towards accentuating the ultra-violet in ordinary illuminants as undesirable. In support of their contention these workers have quoted the results of Widmarck and others, who found that by concentrating ultra-violet light on the eye-lens a turbidity was set up, and the lens

subsequently became semi-opaque. It has even been suggested that cataract is at least partially due to the action of these rays, and the well-known predominance of this defect among glass workers has been ascribed by some to the rays given out by the glowing material. This is now being made the subject of investigation by a special commission of the Royal Society appointed for the purpose. (See Dr. H. T. Parsons, "The Deleterious Effects of Bright Light on the Eyes," *Science Progress*, July, 1909).

Drs. Schanz and Stockhausen have studied the effect of different ranges of ultra-violet light, dividing them into three classes, as shown in the following Table :—

in most of the most recent illuminants. Ordinary glass, it will be observed, cuts off the extreme ultra-violet rays, but yet allows those which Drs. Schanz and Stockhausen consider to be the most dangerous to pass.

I will next perform a few simple experiments illustrating these points. The spectrum of an arc light is thrown upon the screen, the usual gradation of visible energy from red to violet being clearly discernible. But if now I introduce a screen made of barium platino-cyanide into the invisible portion of the spectrum out beyond the ultra violet, the existence of these rays is made evident by vivid green fluorescence. We now see the spectrum extending far beyond the usual violet limit, but these

Action of Ultra-Violet upon the Eye.

I.	II.	III.	IV.
760-400 $\mu\mu$.	400-350 $\mu\mu$.	350-300 $\mu\mu$.	300-0 $\mu\mu$.
Visible Rays.	Ultra-Violet Rays.	Ultra-Violet Rays.	Ultra-Violet Rays.
Reach the retina unaltered in character.	Cause the lens to fluoresce a lavender-grey, reach the retina, and are visible if the lens is removed, or if the visible region of the spectrum is suppressed.	Penetrate the eye, but do not reach the retina. Also absorbed by the eye-lens.	Do not penetrate, but cause inflammation of the outer eye.

They point out further that ordinary glass absorbs the rays from 0·5 μ onwards, but allows those between 0·4 μ and this value, to be transmitted unchecked, and have further devised a special variety of glass—which they term "Euphos"—for the purpose of absorbing these defective rays. Some samples of this glass, by the kindness of the inventors, I am able to show to-night, I believe, for the first time in England. Here, for instance, are a few specimens of chimneys and lamp bulbs made of the glass. For this glass, the authors claim that, although the ultra-violet radiation is so effectively absorbed, only a small proportion of the visible radiation is lost.

Fig. 91, 92, and 93, which exhibit some spectrographs of illuminants illustrating the behaviour of the glass, do not require much explanation. It will be seen that the effect of the introduction of the Euphos glass is to cut off the ultra-violet light sharply, but to allow the visible light to pass, even up to the violet, with comparative ease. The various spectra also make it clear that the presence of an appreciable ultra-violet element is to be traced

remote rays can only be made visible by the aid of some such fluorescent material. In the beam of light striking the prism and giving rise to the spectrum, I now introduce a slab of blue Uviol glass. This glass has the property of stopping nearly all but the violet and ultra-violet rays. The violet is now the only portion of the visible spectrum which can be even imperfectly seen, but the introduction of the sensitive screen or a block of Uranium glass gives rise to the characteristic green fluorescence.

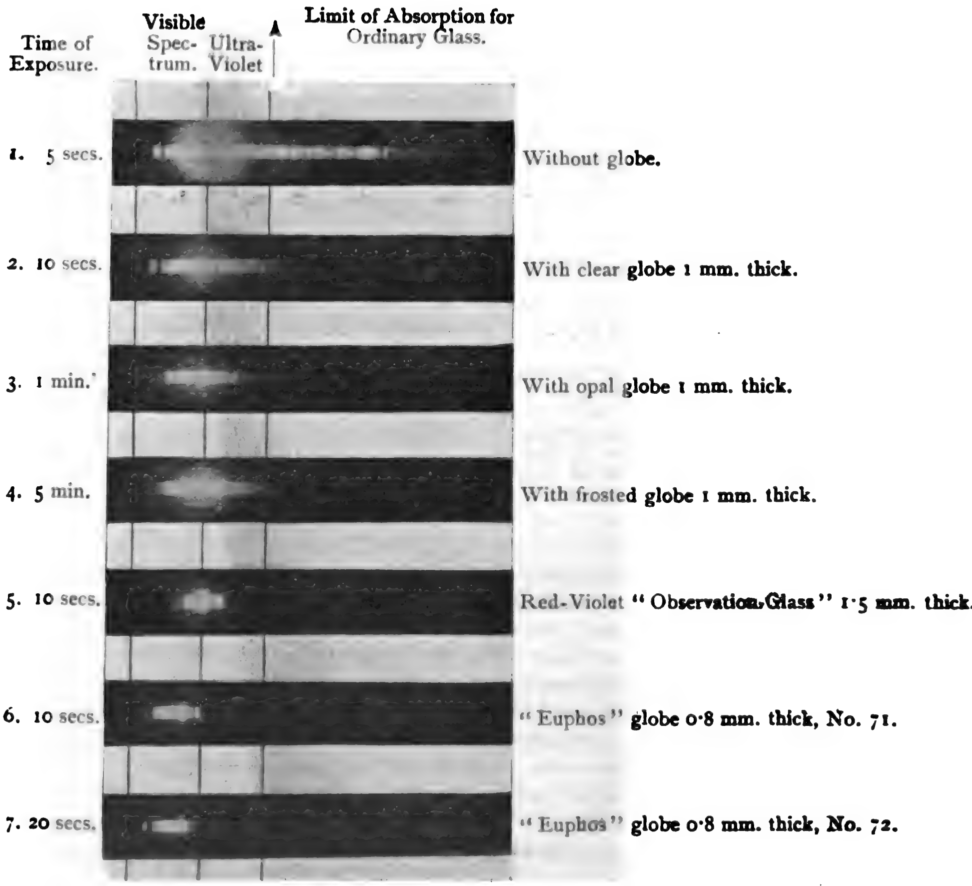
But if I now insert a sheet of the Euphos glass, which you will observe is practically transparent to visible light, in front of the beam, the fluorescence disappears, indicating that the ultra-violet rays have been checked. A piece of ordinary blue window glass, on the other hand, behaves in an exactly opposite manner. That is to say, when introduced in the path of visible light it throws a very dark shadow. Placed in the path of ultra-violet light, on the other hand, it gives rise to practically no shadow at all. In the same way, electric lamp bulbs and chimneys composed of

ordinary glass appear highly transparent to ultra-violet rays, and do not throw any distinct shadow on the fluorescent screen, while those composed of the Euphos glass appear very opaque, and give rise to a sharply-defined shadow.

I have dwelt at some length upon this question, not because I wish to over-emphasise its importance, but because it is typical of that no definite conclusions can be laid down as yet.

Among those who have differed from the two authorities referred to, I may mention Dr. W. Voege, of Hamburg, who has contributed several interesting communications to the *Illuminating Engineer*, stating his own view of the question (Vol. I., p. 775; Vol. II., p. 205).

FIG. 91.



ELECTRIC ARC LAMP, VISIBLE AND ULTRA-VIOLET SPECTRUM AND EFFECT OF EUPHOS GLASS.

many that will crop up in the future, and is one that can only be effectively solved by co-operation between the physicists and the physiologists. In this respect, whatever opinions we may hold as to the validity of their conclusions, the researches of Drs. Schanz and Stockhausen seem to be particularly worthy of imitation. Before leaving the subject, however, it is only fair to say that this matter is still the subject of investigation, and

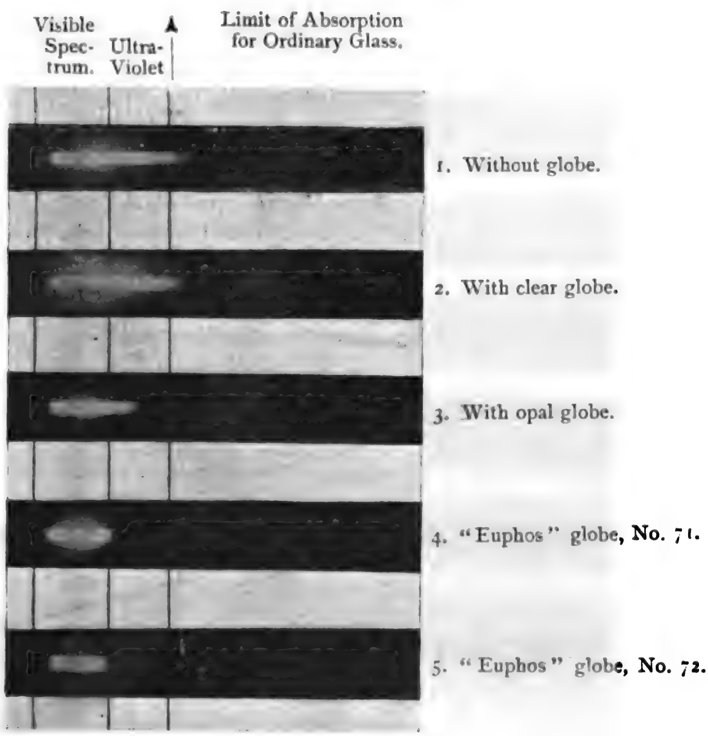
I have made special reference to this subject simply with the object, as I say, of showing how the effective co-operation between physicists and the physiologists may lead to very valuable results. As an illustration, however, that I am not alone in wishing to draw attention to the matter, I may mention that this very question formed the subject of a most animated discussion before the German Institution of Electrical Engineers, at their

annual meeting at Erfurt last year, and I think it is a remarkable recognition of the importance of these physiological questions that a purely engineering society should devote so much time to the subject. In addition, I may mention that the researches of Drs. Schanz and Stockhausen were communicated at the annual meetings of "oculists and others interested in physiological and natural science," (a very important body in Germany), in 1907 and 1908, and this too was an important recognition by the physiological authorities.

Whatever opinion we may hold as to the desirability or need of limiting the ultra-violet constituent in artificial illuminants, used under practical conditions, it will be conceded that when the eyes are exposed to exceptionally powerful doses of ultra-violet energy—in the study of arc-phenomena for example—some means of checking these rays effectually is very desirable. In this connection I might again refer to the work of Dr. W. Voege, who recently published an account of some interesting and useful researches on special spectacles intended to be used in this connection ("Elektrotechnische Zeitschrift," June 3rd, *Illuminating Engineer*, London, August, 1909). Dr. W. Voege finds that deep red glass is specially useful in this connection, when the loss of visible light so caused is of little consequence.

A somewhat interesting case of the injuries which may apparently result from incautious exposure to ultra-violet radiation is furnished by some recent experiences of Dr. Bellile in the French Navy. (*Illuminating Engineer*, London, April, 1909.) This observer records the experiences of some wireless telegraphy operators on certain French battleships who suffered trouble from the eyes which was considered to be due to the ultra-violet light given out by the spark used in connection with the transmitting apparatus. However, as Dr. Voege has pointed out, further data are certainly necessary in order to determine more exactly the part played by the ultra-violet constituent in light

FIG. 92.



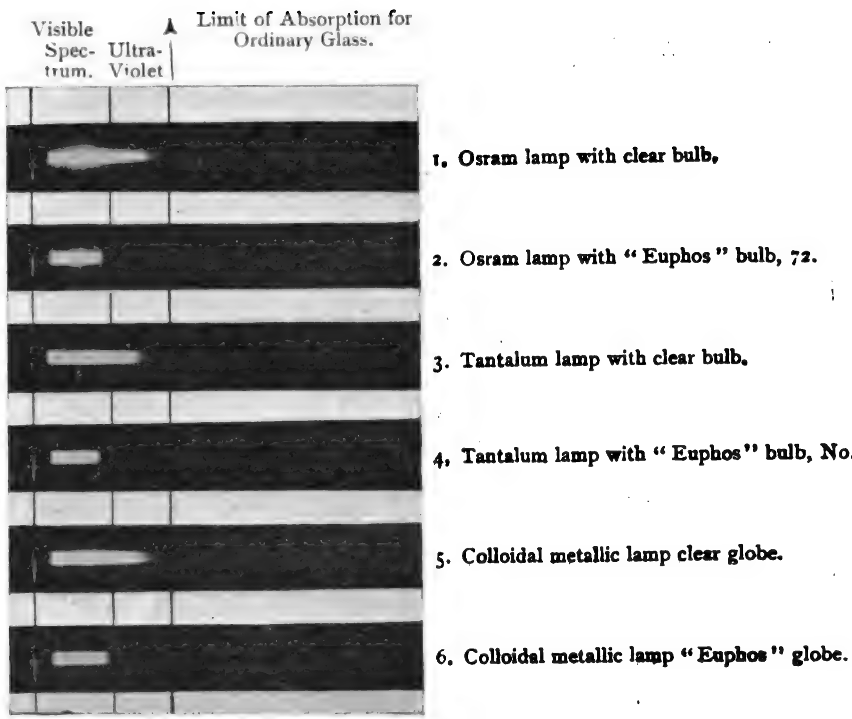
VISIBLE AND ULTRA-VIOLET SPECTRUM OF NERNST LAMP. (Exposure 20 min., showing effect of Euphos glass.)

used under ordinary practical conditions. It is for instance worth noting that according to medical authorities this ultra-violet constituent in sunlight is not without value on account of its supposed germicidal properties, and the free access of sunlight into interiors is regarded as one of the conditions which is most effective in counteracting the effect of any lurking tuberculosis bacilli.

applicable. In addition, such an expert must be a man of wide sympathies, not only willing and able to appreciate the economical and technical aspects of problems, but also in touch with the physiological and aesthetic aspects.

Such a man has yet to be evolved, and I have termed him "the expert illuminating engineer." I need not say that his development must be gradual, and his career for the present largely one of self-education.

FIG. 93.



VISIBLE AND ULTRA-VIOLET SPECTRUM OF METALLIC FILAMENT LAMP. (Time of Exposure 20 min., showing effect of Euphos glass.)

CONCLUSION.

I now come to a few final remarks before winding up this course. If I have done nothing else in these lectures, I hope to have succeeded in giving you an idea of the vastness of this subject, and of the many different points of view that have to be taken into account, and the contradictory data which require to be reconciled. What is needed is a man who shall be independent of any connection with any particular system of lighting, but who will take an impartial and unprejudiced view of them all, and therefore be capable of deciding to what case each particular illuminant is best

It may perhaps seem to some of you that in parts of these lectures I have dwelt in a somewhat pessimistic manner on the defects of modern conditions of lighting, and harped too insistently on the many directions in which there is admittedly room for improvement. It must not be imagined, however, that I do not recognise that there has been most encouraging progress in certain respects, and that modern methods of illumination are in many ways a great advance on those in existence a few years ago. One of the most satisfactory

indications of progress, perhaps, has been the steady growth of interest in matters of illuminating engineering; but what is now needed is to systematise and focus this interest to a greater extent, so that development may proceed on the proper lines. In dwelling on what remains to be done rather than on what has been done, therefore, I have been chiefly influenced by the desire to point out the necessity for such impartial and systematic effort, and the many fields in which substantial improvement might be made through the agency of an Illuminating Engineering Society and the illuminating expert engineer, whose development from existing professions such a society will, it is hoped, eventually bring about.

The urgent need at the present moment is for some method of bringing those interested in different aspects of illumination into one camp—a society which would enable them to appreciate each other's points of view, and would lead to mutual toleration and goodwill. In my paper read before the Society about three years ago, I referred to the need of the illuminating engineer, not dreaming at the time that the subject would have advanced so much as it has in this short period.

The time has now come for the formation of an Illuminating Engineering Society in this country. Many of you may know something of the immense progress and good work done by the society existing with this name in the United States. Since their start over three years ago, the number of members of this society has swelled from ninety-three to over 1,000.

At an informal dinner held on February 9th of this year it was decided to form a similar society in this country. Its object I have tried to explain to you, but I may repeat that all that is desired is a common impartial platform for the free discussion of these problems. Anyone interested in the subject is eligible as a member; at present, the membership will confer no professional status.

At a subsequent meeting on May 25th of this year, the draft-constitution of the society was formally adopted, and since that date the society has received influential support both in this country and on the Continent, from which I have just returned after hearing the views of the chief authorities on illumination, all of whom cordially approved our efforts. It is, I may mention, the intention to give the society as far as possible an international character, in order that concerted action may be taken in the future on matters of international importance.*

Before closing the lecture now, I feel that I ought to express my thanks and keen appreciation of the great kindness of the many who have assisted me, and to whose efforts any good results obtained are largely due.

I will, therefore, first of all, express my thanks to the very large number of manufacturers who have helped in exhibiting apparatus on such a generous scale.†

These lectures may serve as an object-lesson to those who have contended that it is impossible for one man to gain the sympathy of those interested in all the different methods of illumination. I think that you will admit that I have at least tried to preserve an impartial attitude in delivering these lectures.

And next I must express my great indebtedness to the Royal Society of Arts for granting me such exceptional facilities in order to make the exhibition of these systems of lighting possible. I have been allowed the privilege of introducing inflammable substances into this lecture theatre, to run piping, and to cause no little inconvenience by the constant stream of those engaged in the erection of the exhibits. This might be taken, however, as an indication that, with due precaution, all these systems can be regarded as safe methods of lighting and that there is room for the application of them all.

Thanks are due to Professor Stirling for the instructive series of slides and diagrams illustrating the construction of the eye, which he has kindly sent from Manchester University, and also to Professor J. T. Morris and Dr. C. V. Drysdale who have assisted in the same way. I should like in particular to express my appreciation of the services of my assistant, Mr. J. S. Dow, who has helped me throughout with the preparation of these lectures.

If I have inadvertently omitted to make due reference to some apparatus, or did not devote enough time to some points on which fuller discussion may have been desirable, I can only plead the exceptionally wide scope of the subject.

---

* Anyone who would like to hear further particulars regarding this society is invited to apply to Mr. L. Gaster, Hon. Secretary, 32, Victoria-street, London, S.W.

† A list of the exhibits, and the manufacturers who kindly arranged them for these lectures, will be found on pages 291, 3.6, and 348 of the *Journal* for this year.

THE FUTURE WHEAT SUPPLY OF THE WORLD.*

Within a year of the last visit to the Dominion of the British Association the question was raised by the then President of that body at the Bristol meeting of 1898 whether the possible wheat-fields of the globe possessed a potential capacity of expansion sufficient to meet the hypothetical needs of the bread-eaters of even one generation ahead; whether, in fact, a dearth of wheat supply was not already within sight, and by 1931 would be upon us. The fixation of nitrogen, not as a dream but as a certainty, was claimed by Sir William Crookes as the condition on which the great Caucasian race was to avoid being squeezed out of existence by races to whom wheaten bread was not the "staff of life." Personally I confess I am not so pessimistic as to the surface still available for wheat-growing even without this aid. If we granted that the so-called contributory areas, at a date two or three years before the close of last century, were just what was then stated, that the bread-eating population of that date was rightly guessed at 516,500,000—a much more difficult certainty to reach in the manner adopted by the American statistician whose figures were adopted—and that both the growth of population and of "unit consumption" would proceed exactly in the ratio suggested, it might legitimately be asked, does it nevertheless follow that no such increment of area could be looked for as would satisfy the larger mass of consumers calculated as likely to be dependent upon wheat in 1911 or 1931 on the scale here laid down? We might admit that the course of the wheat acreage from 1870 to 1884 and thence onward to 1898 showed—first, a material advance outstripping that of population, then an admitted check with a subsequent advance, although one below that of the bread consumers of the world. Is not, however, a later view of the wheat area at the disposal of the world's consumers well qualified materially to diminish, if not to dissipate, the "cosmic scare" which was induced by the figures of 1898? If the growth of men outstripped the growth of wheat, as was the case between 1884 and 1897, the growth of wheat-fields has been well over the rate of population increase since that exceptional period, just as it was in the still earlier period between 1871 and 1884. Nor was the check to the rye acreage and its decline by four per cent., which seemed to have happened with the wheat check between 1884-1897, continuing; for that, in the aggregate, seems to have returned to, though it has not perhaps much exceeded, the older level. In the decade 1897-1907 the increase to be accounted for was 34,000,000 acres. The Russian quota formed more than a third of the whole. Now it was Russia that was in a very special degree the subject of unfavourable remark in the wheat problem controversy ten years ago. She was spoken of as having reduced her consumption of bread by 14 per cent., only by this means continuing her exports in defiance of her true needs, and contributing to the rest of the world, therefore, a merely provisional and precarious excess.

* Abstracted from the Presidential Address of Major P. G. Craigie, C.B., to the Agricultural Sub-Section of the British Association, Winnipeg, 1909.

Russia.

The exports of wheat from Russia, which we were warned would not continue, and which had doubtless been unusually large between 1893 and 1898, shrank for three years after that date as if they would realise the prophesy which would relegate Russia from the ranks of exporters to the task of feeding her own population. But that mysterious Empire had since then resumed her large supplies, and from 1902 to 1906 the exports ranged higher than before. Although forming only 24 per cent. of her estimated wheat crop, Russia's exports averaged 141,000,000 bushels over the first five years of this century, against 104,000,000 bushels over the whole preceding 15 years. Quite lately we seemed to see some restriction, but the history of the trade forbids a confident opinion that she has reached the end of her contributions to other lands. In the two decades stretching from 1887 to 1906, European Russia had added 1,000,000 acres of wheat per annum. This is not only a 70 per cent. advance in 20 years, but it is double the absolute area of 10,000,000 acres which the United States added in this interval. From such official estimates as were furnished, the total produce of the 50 Governments, where alone the figures were continuous, increased in a still higher ratio. The average production, which did not exceed 180,000,000 bushels in the five years before 1879, or 226,000,000 bushels in the quinquennium ending 1889, reached what appeared to have been a maximum in 1904, and was averaged at 415,000,000 bushels for the whole five years' period then ending. If the later years were again at a lower level, they represented very nearly double the produce before 1879. The yield per acre, which stood below eight bushels to the acre between 1883 and 1892, averaged nine bushels over the next ten years, and has been 10·9, 10·4, and 11·4 bushels respectively in the three seasons ending 1904. In the south-western region, where the yield was just over eleven bushels in the decade ending 1892, it seems to have averaged 15 in the ten years ending 1902, while over 18 and 19 bushels were reported in 1903-1904. These figures omit the Polish, Caucasian, and Asiatic districts, for which a much smaller retrospect is possible. The acreage in Poland is small — little over a million—and nearly constant in extent. But the wheat of Northern Caucasia, first accounted for in 1894, rose from 5,600,000 acres to 8,300,000 in 1906, and the Siberian totals, after increasing, apparently, but slightly, from 3,400,000 acres in 1895 to 4,800,000 acres at the close of the century, do not seem much to exceed 5,000,000 acres now. Inquiry shows that the wheat extension in Russia has been made possible by an actual addition to the arable land, and not by deduction from other crops.

Argentina and Australia.

In the forecasts offered ten years ago Argentina, as a wheat-grower, was given a dozen years from 1898 to reach a possible acreage of 12,000,000 acres. She reached that figure and passed it in less than a decade, and later official current estimates seem to concede to that region a close approximation to 15,000,000 acres to-day. As the actual pace here has bettered so considerably that prophesied, one might legitimately question the further limitations which allowed to Argentina no prospect of ever reaching a wheat area of 30,000,000 acres at any time. No one could note the strides which she has taken in rapidly augmenting her wheat areas and exports, and that concurrently with the commanding place she is assuming as a meat rearer and exporter to the older peoples of Europe, without some recognition that a great future is possible. Small, relatively to the great extent of surface included in the Commonwealth of Australia, is the proportion under wheat, but the Commonwealth is none the less, as a rule, an exporter. A little more than 30 years ago only about 1,400,000 acres were grown. This seems to have been a good deal more than doubled in the 5 years 1876-81, when a much smaller rate of increase followed for 15 years. After 1896 wheat-growing came again into favour, and the rapid spurt which followed brought the Commonwealth total to 5,700,000 acres as the century closed. Thereafter the rate of growth seemed checked anew, and after passing a maximum of just under 6,300,000 acres, it stands to-day under 6,000,000 acres. Twice during the last 20 years has Australia shown on balance a net importation of wheat, but from 1903 to 1907 the quantity exported has averaged 36,000,000 bushels. It is not without interest to observe that the Australian exports of the present century have not all been consumed in Britain; South Africa, the western coasts of South America, and even some parts of India have shared in the surplus product of the Antipodean Continent. The conditions and the future of the Australian wheat have been quite recently dealt with in an interesting paper read before the Colonial Section of the Royal Society of Arts, by Mr. A. E. Humphries, who pointed out that the soils on which it was grown were rich in assimilable nitrogen, requiring little manurial expenditure in that direction, but poor in their percentage of phosphoric acid, while the climatic conditions as regards moisture had proved remarkably difficult. Efforts have been made, and apparently, if recent experiences were confirmed, with success, to breed new varieties of the wheat plant adapted to the peculiar climatic conditions of Australia and likely to increase the low average yields hitherto obtained.

Canada.

The forecast of the Canadian future made in 1898 was surely unduly pessimistic. The opinion then quoted by Sir William Crookes as that of trustworthy authorities, assigned to the Dominion a bare total of 6,000,000 acres under wheat as all that could be expected to be reached within a dozen years. That period has not yet fully come, but by December 31, 1908, the official figure showed an acreage as reached within the decade which exceeded by 10 per cent. the maximum allotted to 1910. If the figure ascertained for the 1909 crop be added, a total of 7,750,000 acres is now reckoned upon, so that here again the forecast has been outstripped. The further proposal to estimate the maximum of the Canadian potential capacity for wheat production by 1923 at no more than 12,000,000 acres would therefore meet severe critics in Winnipeg to-day. It is a relief to turn from the perplexing variety of speculations as to the future to the relatively more solid ground afforded by the actual records of wheat extension. There are defects of continuous statistics showing from year to year the total acreage of the Dominion, although the recent good work of the Census and Statistics Office promises that this will henceforth be remedied. But outside of the three great wheat-growing sections—Ontario, Manitoba, and the North-West—the surface under this cereal is not material. The decline in Ontario, where, as in older settlements, wheat-growing shrank as more diversified forms of agriculture evolved, is much more than compensated for when the acreage of Manitoba, and in later years the rest of the North-West, is superadded, and the rapidity of the recent extension testifies to the energy in the task of bread-raising which this hopeful section of the British Empire displays. But it is clear that our statistical records require a further development and a much improved continuity, especially in the new regions of the wheat supply of the future. Nor can we dispense with the urgent lesson that science has much to teach us in making more use of the areas acknowledged to be under more or less rudimentary cultivation. If Sir William Crookes was right in adopting the American statistician's average of 12·7 bushels per acre as the mean of the recognisable wheat fields of the world, the prospect of the extra seven bushels he sought as immediately desirable would make us eager to learn the very latest triumphs of the laboratory in winning for the soil a freer measure of the nitrogen of the air. But hopefully as we may wait on the chemist's help, I, for my own part, incline still more confidently to the botanist. The producer of new and prolific and yet disease-resisting and frost-defying breeds of wheat plants is to-day more than ever encouraged by what has been done in many lands of late in this direction, to suit the crop to its environment. Nothing could be a greater boon to the wheat farmers, handicapped by a short and irregular supply of summer warmth, and the occasional but often untimely invasion of the frost fiend, than the production of varieties of wheat at once prolific and early ripening, and suited to the relatively scanty moisture of semi-arid regions. The farming of the future must ultimately be one of more careful tillage, of more scientific rotations, and of

consideration for the changes in the grouping of population, and in the world-wide conditions of man and his varying wants. What is going on all over the world has to be learned and studied, and wheat pioneers of the North-West must not forget the possibility of yet new competitors arising in the single task of wheat-growing, whether in the still developing sections of the Russian Empire and the still open levels of Argentina, the little known regions of Manchuria, the basin of the Tigris and Euphrates, the more completely irrigated plains of India, the table-lands of Central Africa, or perhaps under new conditions and a more developed control of the reserves of water supply, on the southern shores of the Mediterranean, or even in the long-tilled valley of the Nile.

THE TURKISH TOBACCO INDUSTRY.

Cigarette tobacco is one of the chief crops, and one of the most important exports, of Turkey. It enjoys a high reputation everywhere. In 1908 the United States alone purchased from Samsoun, in the district of Trebizond, £117,000 of cigarette tobacco. In that part of Turkey, tobacco is grown chiefly at Samsoun, Bafra, Trebizond, and Platana. Very large quantities of Trebizond tobacco are sold to Egypt, where this tobacco is used to brighten the tobacco obtained from other parts of Turkey. Trebizond tobacco is not strong, it has very little aroma, the leaves are large, very light coloured, and do not keep very well. Samsoun and Bafra tobaccos are stronger, have more aroma, do not sting the tongue, while the leaves are smaller and darker. According to the American Consul at Trebizond, the most aromatic kinds are what are called "marden" (mine) and "dere" (valley) varieties. These leaves are very small, strong, dark, and aromatic. The country where the best Turkish tobacco is grown in Trebizond is a low, mountainous region bordering the south shore of the Black Sea. It lies between the 40th and 41st degrees of North latitude. A chain of mountains, once densely wooded, but now quite bare, 2,000 to 8,000 feet high, runs along the coast at varying distances back from the sea, and seems to act as a curtain to hold the clouds and the moisture which rises from the sea. Most of the tobacco fields are on the slopes of the foothills and in the lower valleys, from half a mile to three miles from the shore. As a rule they are small, not exceeding from one to four acres. Snow is not abundant in this region, and there is little frost. It is considered desirable that the ground should freeze a little in the winter before it is cultivated. Rain is quite abundant until June, and the atmosphere is nearly always humid. In the Trebizond district a clear sky and a bright sun are extremely rare. The summer is hot. The tobacco fields are not irrigated. According to the general opinion, it is climate rather than soil that causes the difference in the various kinds of tobacco. The methods of tobacco culture are primitive, and much is left to chance and nature. No systematic rotation of crops is practised, no scientific fertilising, and little cultivating. Some fields are planted with tobacco year after year without any rest, while a few, the least desirable ones, are left fallow every three or four years. About the middle or end of March the seed, mixed with a little sand, is sown on a small bed of ground at one side of the field or in some garden. The starting bed is carefully dug and hoed and cleared from stones and weeds. When the plants are from four to six inches high they are transplanted in the field, and set out in rows about eight inches apart, and the plants placed about a foot apart in the rows. They are watered once or twice when first set out, and rarely after that. Little weeding or cultivating is done. No machines are used. At Trebizond, when the tobacco is from twelve to fifteen inches high, the tops are broken off and the shoots are pinched. A few stocks are left for seed. At Samsoun, little or no budding or pinching is done. There they try to get many small leaves, while at Trebizond they look for large leaves—quantity rather than quality. Harvesting begins in the latter part of June, and the pickings follow one another throughout the summer. At Trebizond there are three pickings:—(1) The lowest leaves and the poorest in quality; (2) medium leaves of medium quality; (3) the best quality, large leaves, strong and of darker colour. The seeds are gathered in September and no use is made of them except for planting. In Trebizond the average yield is about 800 pounds of tobacco per acre. In Samsoun it is about 750 pounds, and in Bafra it averages about 900 pounds per acre. In 1908 Trebizond, including Platana, produced about 60,000 hundredweight. The leaves, as gathered, are placed on strings, each quality by itself, and the strings are hung on horizontal poles. They are dried in the sun near a cabin so arranged that in case of rain the poles can easily be run into the cabin to protect the tobacco. After the leaves have been well dried they are put into a damp house or cellar where they remain until they become soft when they are made up into packets of six to ten leaves. Subsequently they are taken to the Tobacco Régie depots where they are sorted, manipulated, weighed, and sold either to the Régie or to the tobacco merchants.

TRADE IN SOUTHERN PERSIA.

Major Ducat, H.M.'s Consul at Kerman, has just sent home his report on the trade of his consular district for the year ended March last, and dwells at some length on the moot question of transport in Southern Persia, which has been the subject of frequent discussion and comment for a few years past. It may be remembered that in 1906 a Com-

mercial Mission to Southern Persia was organised by the Chambers of Commerce in Northern India, with the approval and assistance of the Government, and placed in charge of Mr. Gleadowe-Newcomen, who, on his return, drew up a most interesting report on the subject, a summary of which appeared in the *Journals* of March 29th, and April 5th and 12th, 1907. Since then the conclusion of the Anglo-Russian agreement has definitely placed Southern Persia in the sphere of Great Britain, and has drawn renewed attention to the necessity of doing all that is possible, in the interests of British trade, to open up the country and develop its means of transport. Towards the close of last year, a City company entered somewhat exhaustively into the subject, and was advised that the first great requirement was the construction of a good road from Bunder Abbas, *viâ* Regan and Bam, to Kerman. Estimates were duly obtained, but the revolutionary movements in the Shah's dominions and the disturbed condition of the country prevented the project from being carried out.

Major Ducat now enters fully into the same subject. He points out that the position of Kerman is one of exceptional importance. It occupies the summit of the great plateau of Persia at an altitude of some 6,000 feet, and between it and the other large towns on the plateau — Teheran, Ispahan, Shiraz, Yezd, and Kashan—there is no range of mountains or any obstacle to a road or railway. It is the only large town on the plateau which can be reached from the sea without any serious obstacle, or to which a road or railway would entail no heavy cost or engineering difficulty, and some day it will be the chief large inland town on the main southern route into Persia. Meantime, however, though the caravan route has no kotals (passes) to surmount, has good water all the way, and halting places with provisions at convenient intervals throughout, it is probably worse provided with transport than any known route in the world connecting a town of 60,000 inhabitants, with a busy seaport 350 miles away. There is no organised carriage service, and consignees are entirely at the mercy of a few ignorant and short-sighted camel drivers, who will flatly refuse to take an unusually shaped package at all, and even for merchandise, packed specially, will unblushingly make a written contract to deliver within 80 to 90 days at a rate of about £12 10s. a ton. During 2½ years' experience, Major Ducat says, the shortest time he has known a caravan to arrive in has been 35 days, and as even a camel covers 2½ miles an hour, this means an average day's march of four hours with five halts. The postal service, when it was in working order, took 20 to 30 days to deliver a weekly mail from Bunder Abbas, and now letters drop in at intervals of five and six weeks. Telegrams from Kerman to Bunder Abbas first go north to Teheran, then south to Bushire, from Bushire to the island of Herijam by cable, and thence from Herijam to Bunder Abbas by boat, when one happens to be available, and weather permits.

Meantime the roads have been impossible except for well-armed parties able to beat off attacks, the mails have practically ceased coming, and communications have been more and more restricted. As a matter of fact, transport has never been easy to obtain in the district, and, if the reported robberies are authentic, all the transport animals except camels are in or have passed through the hands of robbers. Among the imports figure piece goods, yarns, sugar, tea, matches, indigo, copper, candles, and coffee, while the well-known Kerman carpets are the principal exports, these varying in size from the small "pushti" (1 foot by 2 feet) to the large carpet for the hall and the "biggest in the world" hotels of New York. The total value of carpets exported was £90,000 in 1908-9, and is likely to increase so far as New York trade is concerned, though the trade to Constantinople, the only other mart, may fall off in proportion. The other exports are natural produce, such as gum, almonds, and pistachio nuts, or raw material like wool, cotton, and hides.

The description given by Major Ducat of the life and wants of the people, points to a very primitive state of society. From a trade point of view their education is practically untouched. Their wants are still almost confined to necessary food and scant clothing. Obtaining easily these simple wants, and having no knowledge of any others, or means of satisfying them if they have, they contentedly idle away nearly a quarter of the year. Though not a third of them really keep the fast, practically no work is done throughout the month of Ramazan. It is equally impossible to get anything done during the month of Maharram. From Naoroz till the thirteenth day after every man, woman, and child is holiday making, and every month of the Mahommedan calendar has one or more "eeds," or "katls," which are kept as holidays. In the winter if there is a heavy fall of snow, or a particularly cold snap, the bazaars close, and everyone sits indoors over a colossal brazier for a week if it lasts so long. Major Ducat says that to send him catalogues of motor launches, mining and boring machinery, steel structures for buildings, or inquiries for the addresses of shipbuilders and ship chandlers, denotes more ignorance of the geography and civilisation of the district than an intelligent effort to extend markets.

THE OUTLOOK FOR TIMBER SUPPLIES.*

Much attention has recently been given to this subject, and the general opinion is that prospects are not reassuring. Britain paid twenty-seven millions sterling for wood on the average of the five years 1904-8, as compared with eighteen millions in 1889-93, an increase of 50 per cent. Even Germany, with nearly twelve times the area of forest that we possess, pays annually some twelve millions sterling for im-

* Abstract of a paper read by Professor W. Somerville before the Agricultural Sub-Section of the British Association, Winnipeg, 1909.

ported timber. Although the U.S.A. exports wood and wood-products to the value of twenty millions sterling per annum, she has to pay as much for imports. In Europe, Sweden and Russia are the chief timber-exporting countries, and it seems unlikely that these countries can maintain supplies. Sweden, it is officially stated, is over-cutting her forests to the extent of more than 100 million cubic feet yearly, while Russia is already reducing her exports. In various official publications the Department of Agriculture of the United States has drawn attention to the prodigal method in which her forests are exploited, and has pointed out that in a few years she will not even have timber enough for her own supplies.

There are only two regions of the world that may contain sufficient areas of virgin coniferous forest appreciably to affect the situation. The one is Canada, which in the North-West, and also North and East of Lake Superior, contains large tracts of untouched forest. The growing stock of large stretches of country west of the Rocky Mountains is undoubtedly large, and is now having an appreciable effect on market supplies. The timber that may become available along the line of the new Grand Trunk Railway is more problematical. The area is vast, but the density of the stock is said to be poor, and the individual trees and rate of growth are small. The other region of the world that contains large stretches of virgin forest is Siberia. Although the density of Siberian forests cannot compare with well-stocked land in Europe or America, her areas are so vast that it cannot be doubted that this country possesses enormous stores of wood. But the difficulty in her case is to get them out. The navigation of the Arctic Ocean is too dangerous to be undertaken for timber cargoes at anything like present prices. Nor would it be profitable to move timber along the Trans-Siberian Railway. The only way to get part of Siberia's timber to market is to float or ship it down the rivers, such as the Amur, that debouch into the Pacific. This is already being done to some extent, and in time such supplies will go some way towards satisfying the demands of China, Japan, and Australia.

The growing scarcity of timber is clearly reflected in the supplies on the world's markets. Thus in Britain the largest class of timber has risen in value 28 per cent. in the last fifteen years. Concurrently with the rise in price there has been a marked falling off in quality, so that the real rise in price has been much more than the figures indicate. The United States Department of Agriculture recently issued a table, which showed the prices ruling for various classes of timber in various American markets during the past twenty-two years. Of thirty-two brands of timber, nine had risen over 100 per cent., and only two had risen less than 25 per cent. Effective relief through the agency of timber substitutes seems improbable. Concrete and iron are, of course, used to some extent in place of wood, and there is a talk of sugar-cane stalks becoming important in paper-making. But with it all, the demand for wood continues to grow, and although economic prophecies have often proved to be wrong, it seems impossible to escape the conclusion that the future of the world's timber supplies is distinctly disconcerting. It would therefore appear to be in the interests of every country to take energetic steps to prevent the wasteful destruction of timber by forest fires, to see that denuded areas are at once regenerated, and to undertake the planting of all land that can be better utilised under silviculture than through the agency of pastoral occupation.

HOME INDUSTRIES.

The Wheat Position.—The comparatively high prices of last year induced wheat growers to increase the area of cultivation, and the crops of wheat from this increased area are expected to yield at least an average production per acre. The Hungarian Minister of Agriculture, in his usual forecast of the world's crops, estimates the total yield of wheat this year at 432,087,000 quarters, as against 397,257,000 quarters last year, an increase of 32,830,000 quarters. *The Times* estimate is some 9,000,000 quarters less, at 423,000,000 quarters, and it puts the figures for last year at 393,000,000 quarters. Assuming these latter figures to be near the mark, the prospects this year are for a total yield of 3,000,000 quarters more than last year's production. It is estimated that countries not growing wheat enough for home consumption will need to import roughly 70,000,000 quarters, and to meet these requirements the exporting countries are estimated to have a surplus of fully 81,000,000 quarters, the United States coming first with 20,000,000 quarters, and Russia and Argentina next with 13,000,000 quarters. If these estimates are approximately correct, the world's crops may yield some 11,000,000 quarters above the world's requirements for the year ended August 31st, 1910. This would seem to mean a further reduction in prices, which have already fallen considerably as compared with the high-water mark of two months ago, English white wheat from 45s. 6d.-48s. to 39s.-42s., Australian from 47s. to 44s., La Plata from 46s. 6d.-47s. to 44s., and South Russian from 47s.-47s. 6d. to 39s. 6d.-42s. 6d. But it must be remembered that, owing to two years of short crops and high average prices, the supplies in sight are less than half the quantity in view two years ago, and the invisible supply has also been severely trenched upon. It is estimated that the wheat in sight at the beginning of September was some 7,000,000 quarters less than two years ago. The visible supply in the United States has fallen from 6,500,000 quarters two years ago, to 1,142,000 quarters in 1909; the stocks at United Kingdom ports have fallen in the same period from 2,405,000 quarters to 1,110,000 quarters; stocks on the Continent from 900,000 quarters to 600,000 quarters;

whilst the quantity afloat for the United Kingdom, and for orders, has shrunk from 2,160,000 quarters in 1907 to 2,065,000, and the total quantity afloat for the Continent has increased from 1,110,000 quarters to 1,265,000, the total visible supply in 1909 being 6,182,000 quarters as against 13,075,000 quarters in 1907. On the whole, it seems probable that there will be some further decline in prices.

The Trade Boards Bill.—As was anticipated, this Bill met with no difficulty in its passage through the House of Lords, and it is greatly to be hoped that it will fulfil, or partially fulfil, the expectations of its authors. But experience of the legislative attempts to ameliorate the condition of the residuum warrants a certain scepticism. Everyone sympathises with the object of the Act, the prevention of sweating; everyone hopes that it will get rid of the sweater, and that his disappearance will mean fair wages for the sempstress and her like. But will it get rid of the sweater? Sweating is now a punishable offence, but it is not all punishable offences that are punished. If the law ordered the sweater to pay fair wages, and compelled him to do so, his workpeople would benefit in the way in which it is assumed by many the Trade Boards Act will benefit them. But Parliament has passed no such enactment, and if it had it could not enforce it. What it has done is to order the sweater not to pay wages below a minimum. And this direction will force him to do one of two things. Either he will give up his business, or, by the collusion of his workpeople, he will evade the law. He is not at all likely to change the character or methods of his business, and it must be remembered that many, if not most, of his workpeople are unequal to the good work for which those who pay the minimum wage will stipulate. It is sweated work under conditions which destroy health, and make life not worth living, but they prefer, say, 5s. a week to nothing. At least a large percentage of them know that they will never get the higher wage the law says ought to be theirs, and they prefer the sweater's wage to none. If that be so employer and employed are likely to join in hoodwinking the law. There are many Acts in force for the better housing of the poor, but the good that was expected to result from them has not accrued in anything like full measure because landlord and tenant unite to evade the Acts. And so it may well be with the Trade Boards Act. The sempstress and others included in the Act will not, it is to be feared, be the allies of the Government in enforcing it because it will seem to them that "a half loaf is better than none," and they may not be persuaded that the Act will give them the whole loaf.

Machinery Cleaning.—According to the "Textile Recorder," a method is now being employed in the United States by which compressed air is used to blow the dust and fibrous accumulations off machinery, the air being conveyed thereto by means of a flexible tube with a metal nozzle. When humidifying installations are of the pressure type they may be used to supply the air for the cleaning tubes. The "Textile Recorder" instances the case of a spinning mill in which records have been kept for twelve months, the saving effected being approximately £9 per 1,000 spindles per annum. The vacuum cleaning method has also been attempted, but not very successfully. In England there is small heed to the waste of time caused by machinery cleaning. Usually the engine stands for a short time once or twice a week, say in all an hour. Taking the working hours per week at 55, this means a loss in output of about 2 per cent.

Nitrates from Air.—The British Consul-General at Berlin, reporting upon the manufacture in Germany of nitrates from air, says that the industry is still in the first stage of development. In full working order the principal German works at present engaged in the manufacture can produce about 21,500 tons of nitrate of lime per annum, a quantity which will be increased to about 41,500 tons when the plant now in course of construction is completed and in operation. Projects for a number of other works are under consideration, the most important being the erection of large nitrate of lime works in Bavaria. A factory has also been built in the Tyrol by a Westphalian company, which is capable of producing about 3,000 tons of nitric acid, and from this a corresponding quantity of nitrate of lime. It is estimated that about 1,300 tons of nitrate of lime were sold in Germany in January and February last. At this rate, the sales for the whole year will amount to over 7,500 tons, or about 1½ per cent. of the total quantity of natural saltpetre annually consumed in the country. As more works are completed, the manufacture of this artificial manure must increase, but probably a considerable time will elapse before it seriously affects the natural product.

Sunday Work at Sea.—In January last, the Board of Trade sent out a letter, addressed severally to the Chamber of Shipping of the United Kingdom, the Shipping Federation, and the Liverpool Steamship Owners' Association, dealing with the question of Sunday labour on board British ships when lying in port, whether at home or abroad. The Board, whilst recognising that the varying conditions under which British merchant ships carry on their business in different parts of the world, make it difficult, if not impracticable, to lay down hard and fast rules as to what work the crew may properly be required to perform on Sunday, are satisfied that they may rely upon the co-operation of shipowners in restricting such work within the narrowest possible limits. And the Board went on to suggest that any reasonable ground for dissatisfaction might to a large extent be removed if the officers and crew of a vessel received extra remuneration in cases where work on Sunday in port is found to be essential. The shipping bodies addressed were asked if they saw any objection to the insertion of a stipulation in the printed form of agreement providing that the officers and crew shall receive

extra pay at a stated rate per hour when called upon to perform work in port on Sunday. The shipowners have emphatically rejected this suggestion. They say that not only would any differentiation in the days of duty applicable to seamen cause friction and disorganisation of work on board ship, but it would still further handicap British shipowners in their struggle with foreign competitors whose working expenses are already so much less costly than in British vessels, but such a stipulation would defeat the object aimed at and increase rather than lessen Sunday labour. The Chamber of Shipping of the United Kingdom gave it as their opinion—an opinion endorsed by the other shipping authorities consulted—that officers and crews are, as a rule, so desirous of receiving extra pay that if such a hard-and-fast clause as that suggested were to be put into ships' articles the work of the ship would be planned by the officers so as to render it necessary that work should be performed on board ships in port on Sunday.

OBITUARY.

John Jones.—By the death of Mr. John Jones, which happened on the 6th instant, at his residence, Manor-house, Send Green, Surrey, in his 95th year, the Society loses its oldest member, since he joined it sixty-six years ago, in 1843. Up to 1907 he paid an annual subscription, and on his expressing a wish to retire, since at his great age he could no longer even read the *Journal*, the Council felt justified in electing to life membership one who had so long supported the Society. Until age made him retire from business, Mr. Jones took a very active interest in the work of the Society, frequently contributed to the discussions, and wrote letters to the *Journal*. He was a man of energetic character, and of an independent turn of mind, and never hesitated to give expression to his opinions. His first appearance in the *Journal* appears to have been in 1856, when he wrote protesting against certificated schoolmasters not being permitted to enter for the Society's examinations. His last appearance was in 1881, when he took part in the discussion on an interesting paper, by Mr. Berly, on "Pneumatic Clocks," then lately introduced into Paris. Mr. Jones was in business as a watchmaker, and seems to have been the first to introduce a moderate priced watch. "Jones's Workman's Watch" was well known for its low cost and good quality at a time when it was impossible to obtain a trustworthy timekeeper, except at a very considerable price.

He was perhaps the first to suggest the encouragement of technical education by the City Companies, when in 1854 he induced the Turners' Company, of which he was one time Master, to offer rewards for turnery. He was an active and respected member of the Common Council, where, as elsewhere, he had a habit of speaking his mind. He was also a member of the Metropolitan Board of Works at the time of its dissolution.

GENERAL NOTES.

The Illuminating Engineering Society.—This Society will enter upon its opening Session next November. Prof. Silvanus P. Thompson, D.Sc., F.R.S., has consented to be the first President, and influential support has been received from many distinguished authorities on matters of illumination in this country, on the Continent, and in America. Among those who have expressed their sympathy with the movement by becoming Vice-Presidents and Corresponding Members are:—Dr. Bell (Boston, U.S.A.), Dr. L. Bloch (Berlin), Prof. A. Blondel (Paris), Dr. E. Budde (Berlin), Prof. H. Bunte (Karlsruhe), Sir William Crookes (London), M. Sainte Claire Deville (Paris), Prof. H. Drehschmidt (Berlin), Mr. E. L. Elliott (New York), Dr. A. H. Elliott (New York), Prof. J. A. Fleming (London), Dr. E. P. Hyde (Ohio, U.S.A.), Dr. H. Krüss (Hamburg), Mr. V. R. Lansingh (New York), Prof. Vivian Lewes (London), Sir William Preece (London), Sir Boverton Redwood (London), Prof. S. Rumi (Genoa), Dr. E. Schilling (Munich), Prof. H. Strache (Vienna), Prof. K. Ulbricht (Dresden), Dr. W. Voege (Hamburg), Sir H. Trueman Wood (London), &c. Any one interested in the objects of the Society and desiring to become a member is invited to apply to Mr. L. Gaster, Hon. Secretary, 32, Victoria-street, London, S.W.

The Cost of Living in Bahia.—In his report on the trade of Bahia just issued (No. 4313, Annual Series), Mr. Consul O'Sullivan-Beare gives some striking figures to illustrate the high cost of living at Bahia consequent upon the heavy import duties plus local taxation. The Federal Government has imposed on Bahia, in addition to ordinary duties, a special tax of 2 per cent. gold upon all articles imported. The proceeds of the tax serve as a guarantee in connection with the scheme of projected harbour works at the port. To take some of the Consul's figures:—

	Cost. Reis.	Duties. Reis.	Percentage of duties. Reis.
Jams	16$000	34$000	212
Onions	220,000	1,356,000	616
Tinned vegetables ..	18,000	62,000	344
Wines	102,400	268,000	262
Brandies	13,000	40,000	310
Whiskies	15,000	33,000	220

Dried vegetables pay duties varying from 80 to 260 per cent.; cheese pays 131 per cent.; cocoa 161 per cent.; chocolate 221 per cent.; ham, 100 per cent., and so on.

Journal of the Royal Society of Arts.

No. 2,965. VOL. LVII.

FRIDAY, SEPTEMBER 17, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

THE MAHRATTA PLOUGH.

By Sir George Birdwood.

In omni quidem parte culturæ, sed in hac quidem, [*i.e.*, arandi disciplina] maxime valeat oraculum illud: "Quid quæque regio patiatur."—C. Plinii, "Nat. Hist.," xviii. 18.

This defence of the Mahratta plough was originally written in reply to the sweeping attack on the vernacular implements and operations of Indian agriculture, made in a paper read on the 16th of July, 1888, before the East India Association, by the Pandit Srilal, a distinguished student of the Royal Agricultural College at Cirencester, and late Secretary to the Agricultural Society of Bijnaur, the northernmost District of the Rohilkand Division of the North-West Provinces. As it would not be possible within the space at my disposal to attempt a general rejoinder to the accomplished Pandit, I restrict myself, for the present, to the vindication of the indigenous plough, in regard to its perfect adaptation to the surrounding conditions of the land, and life, and labour; and in so doing I confine myself to that part of India known to me familiarly, in the strict etymological sense of the word, from my birth, and dear to me as my native country,* the "great" basaltic "kingdom" of Maha-rashtra.

* The name of my birth-place, Belgaum, is Canarese, its correct form being Vennu-grama [" Bamboo—my 'Tree of Life'—Town"], and it was included within the limits of the ancient Karnataka, or "Canara [literally "Black Soil"] Country." The Mahratta language is, however, spoken right up to Belgaum, and the Ghat-prabha [" Pass-leader"—my "River of Life"—] river rising by numerous affluents in the Sabyadri mountains [" Western Ghauts"] between the Hanuman and Ram *ghats* or "passes," and flowing past Belgaum and Gokak, westward to the Kistna, now bounds the extremest southern marches of "the Mahratta Country"; and, up to its junction with the Kistna, divides the basaltic formation of Maha-rashtra, from the granite plateau of Karnataka.

PART I

The Mahratta Country, or "Ager,—*aut rudis et immanis, aut silvosus, aut arvus,* [i.e., *aratus et consitus,*] *aut pascuus, aut florens.*"

Its Limits.

Hindu geographers divide the Dakhan, or India "south" of Hindustan [the alluvial plains of the Indus and Ganges] into six principal provinces—viz., (1) Guja-rashtra, north-west of the Narbada; (2) Gondwana [the Central Provinces], south-east of the Narbada; (3) Andra or Telingana [the Nizam's Dominions, *et cetera*], south of Gondwana, to the Coromandel Coast; (4) Dravida [Travancore, *et cetera*], in the south of the peninsula; (5) Karnataka [Mysore, *et cetera*], on the Malabar Coast, north of Dravida; and (6) Maha-rashtra, extending from the Ghat-prabha river—which separates Maha-rashtra from Karnataka,—nearly 500 miles north to the Satpura mountains the watershed between the Tapti and Narbada rivers; and from the Malabar Coast, 300 to 400 miles eastward to the borders of Telingana and Gondwana; the westward border of the latter province being defined by the Wardha river, a northern affluent of the Godavari.

These are the extreme ethnographical frontiers of the Mahratta Country; but its political limits have been enlarged by conquest even beyond them;—past the Wardha river, and past the old Bhonsla city of Nagpur, right up to the Wain-ganga, the eastward affluent of the Godavari; and again across the Narbada, where Mahratta dynasties have permanently established themselves at Baroda [Gaekwar] in Guzarat, and at Indor [Holkar], and Gwalior [Sindhia] in Central India. These subject Mahratta States are, however, excluded from the present survey; as are also the Khandesh District [Baglana], or basin of the Tapti, be-

tween the Satpura mountains and the Chandor hills; and the whole of the Nasik District; and all the six northern subdivisions of the Ahmadnagar District, forming with the Nasik District, between the Chandor and the Ahmadnagar hills, the fluviatile area, wherein are gathered, by its head stream and western affluents, the waters discharged by the pastoral Godavari, through Telingana, into the Bay of Bengal. The latter tracts are termed, indiscriminately, by the Mahrattas themselves, Vindhyari, that is, belonging to the Vindhya ["the Hunters'"] mountains, and are still in large proportion peopled by the Bhils* ["Bowmen"], and other aboriginal tribes, who, from the remotest prehistoric times have had their home in Gondwana, whereto Khandesh truly appertains, rather than to Maha-rashtra.

The boundaries of the true Mahratta Country, therefore, are:—on the West, the Arabian Sea from Goa to Bombay, 250 miles; on the North, the Kalyan river from Bombay to the Sahyadri mountains, at the Malsaj *ghat*, 70 miles as the crow flies, and thence, along the Ahmadnagar hills, so far as they extend due east, 100 miles more; on the East, the south-eastern prolongation of the Ahmadnagar hills to beyond the sacred Mahratta city of Tuljapur, and the fortress of Nuldrug, both in the Nizam's Dominions, 120 miles in all; and on the South, an irregular line from Nuldrug to Goa, crossing the Bhima, the great contributory to the Kistna from "the Northern Mahratta Country" [the Ahmadnagar, Poona, Satara, and Sholapur Districts], about 60 miles south-east from Pandharpur, the holiest of Mahratta towns, and the main stream of the Kistna itself, 30 miles south from the splendid ruins of the mediæval Moslem city of Bijapur, and just east of the influence of the Ghat-prabha, the south-most contributory to the Kistna from "the Southern Mahratta Country" [the Kolapur State, and Bijapur and Belgaum Districts], a distance, as the crow flies, of altogether 200 miles.

Within the area thus circumscribed, the most characteristic Mahratta territory is, according to Grant-Duff, the region of upland dales, about 50 miles in breadth, and 200 in length, extending across all the eastward spurs of the Sahyadri mountains ["Western Ghats"] from Junnar on the Bhima, southward through Poona, the capital of the old Mahratta Peshwas,* on the Muta Mula, an affluent of the Bhima, and through Satara, on the head stream of the Kistna, to Euru-Manjira, lower down the same river, a little east of Kolhapur. These mountain valleys, locally termed *mavals*; and the wide straths of the Bhima, and its affluents the Sina and Nira,—[the Bhima and Sina, rivers flowing side by side, between the Ahmadnagar and the Poona hills, and the Nira between the Poona and the Satara, or Mahadeo hills, and the open vale of the Kistna, where it opens out southward from Satara, and away east from Kolhapur, into Telingana, together with the precipitous, low lying, narrow maritime belt of the Konkans, to the west of the Syhadri mountains],—all this well wooded, and well watered, and well laboured, fertile, and inaccessible, and strongly defensible country, is "the very heart of heart" of the mighty basaltic tableland of Maha-rashtra: toward which the hearts of all its true sons, the hardy, brave, shrewd, hospitable, and intensely devout *mavalis*, the Scotch of India, are drawn, as with a fourfold cord, by its romantic and sublime picturesqueness, its bounteous fruitfulness, its profoundly emotional associations with the religious poetry of Tukaram [*circa* 1609 to 1649], and by the heroic history of Sivaji [1627 to 1680]: —Tukaram, who passionately extols the glory of Vithoba or Vithal, the popular incarnation of [Krishna]-Vishnu, and of Pandharpur, the seat of Vithoba's noblest shrine, and of the Bhima, the perennially flowing, broad-meadowed river of Panharpur;—and Sivaji, the typical and greatest leader of the historic Mahratta race, at once their Wallace and Bruce and Douglas, to whom they owe the imperishable and inspiriting memories of an independent national life centred for 108 years [1650 to 1818] at Poona; this city, on account of its commanding strategic position,

* The Mahrattas are mixed, but true Aryas, and represent the south-west extension, *en masse*, of the Aryan race in India. The Bhils are unmixed aborigines, or Vindhyan Dravidas, and are represented south of Khandesh by the Varalis [north of Bombay], Kathodis [north of Poona], Ramusis [north of Kolhapur], and other semi-savage tribes of "the Western Ghauts," who form the autochthonous substratum of the lower out-castes of the gallant Mahratta nation.

* The Pesh-wa [literally "Fore-man"], was the Prime Minister of the Mahratta kings; and the office becoming hereditary in the family of Balaji Rao, they gradually usurped the supreme authority, reigning in great power at Puna [Poona] between A.D. 1718 and 1818: leaving to the royal family of Sivaji only the petty principalities of Satara and Kolhapur. The word *pesh* in their title is Persian, and occurs also in Peshawar, "the *Frontier* station," in Peshin, "the *Front*-land," *i.e.*, "Sun-rise," or "Morning-land [Anatolia], as viewed from Persia; and in such words as *pesh-kash*, "what is *fore*-drawn, *i.e.*, "first-fruits, "taxes": *pesh-qi*, "money *advanced*"; *pesh-kabs*, "*fore*-grip," a dagger, the blade of which curves forwardly from the handle; *pesh-ani*, "the *fore*-head"; *pesh-ab*, "*fore*-water, *i.e.*, οὖρον, et cetera.

still maintaining its pre-eminence as the military capital of the Dakhan. It is the Kabul of Southern India; and as, according to the Eastern proverb:—"The Master of Kabul is the Master of Hindustan," so a ruler strongly seated in Poona, holds the entire Dakhan in his all confronting power.

I retain from childhood a lively recollection of the scenery and people of the whole of Maha-rashtra, between Belgaum and Indor, and Surat and Asirghar;* while with the Mahratta Country, as known to me in later years, and comprised within the administrative Districts of Poona, Ahmadnagar, Sholapur, Satara, Kolhapur [native State], Bijapur, and Belgaum, and, in the Southern Konkan, of Goa [Portuguese possession], Sawantwari [native State], Ratnagiri, and Kolaba, and, in the Northern Konkan, of Thana, I am more intimately acquainted than with any part of the United Kingdom, unless excepting the basaltic plains of the Forth and Clyde.

The Sahyadris.

The Sahyadris are the crest of the great wave of trap covering the whole of the western Dakhan from Belgaum to Indor, and from the Central Provinces to the Konkans, over which it hangs like a citadel of the Cyclops; attaining in the flat-topped mountain mass of Mahabal-eshwar, "the Great-strength-of God," its greatest height, 5,000 feet above the sea.

This aerial ramp lies almost at right angles to the direction of the South-West Monsoon, which beating on it through incalculable ages, has worn its sky line, where the trap rock is of harder basalt, into prolonged chains of bluff, flat-topped, terraced headlands; and, where of softer amygdaloid, into an occasional jagged peak; and at a lower height has moulded it, by the same process of secular denudation, into the confused maze of lateral spurs, between which the rain water of the Monsoon runs off in the head springs of the Kistna towards the east, and on the west in the numerous little rivers that plough their rapid way to the Arabian Sea through the Konkans. The black soil of the plains of the Dakhan has been chiefly formed from the Monsoon waste of the Sahyadris; and this soil, so well adapted to the cultivation of cotton, extends beyond the trappean tract of Western India, far into the south and east of peninsular India, where it gives its name both to Karnataka and the Kanaras.

The Konkans.

These mountains fall toward the west very abruptly, in terraced slopes, of alternate horizontal belts of evergreen woods and black bands of basalt, and sheer precipices, often of 2,000 feet deep, and rugged, irregular spurs, often reaching the sea in 20, or in some places 40 miles, and cutting up the Konkans into a succession of transverse ravines and gorges of incredible difficulty, and deep steaming valleys, covered with thick forests, mostly of bamboo and teak. On the flat top of an isolated hill of one of these spurs, stretched out between the Bor *ghat* and Bombay, Lord Elphinstone founded the sanatorium of Matha-ran ["The Top- of the wild"]. Rising abruptly, from almost the level of the sea, to a height of 2,500 feet, and standing like an advanced tower in front of the Sahyadris, it commands the most striking panoramic view of them, from the stupendous scarp of Harichandragar [Malsaj *ghat*] rising to an altitude of 4,000 feet, in the north, to the pinnacled precipice, called by the natives Nagphani, "The Cobra's Hood," and by Europeans, "The Duke's Nose," on the east, there marking the position of the Bor *ghat*, down to the levelled loom line of the mighty bluff of Mahabaleshwar in the extreme south.

The "Island of Bombay."

Matharan, and the twin flat-topped Prabal hill, and the remarkable, curiously serrated, saddle-back ridge of Bawa Malang, and the Panala Hill, surmounted by the basaltic column that gives it the name of Funnel

* Asirghar is one of the finest stations in India for the observation of sunrises and sunsets, and moonlight effects. In the clear sapphire of the earth's shadow we call the night the stars do not shimmer, but shine with the bright steady glow of distant orbs hanging at different altitudes in the illimitable heights of the heavens; and the face of the moon is seen in full relief, and to be not of silvern, but of a pearly radiance of the most exquisite nacre. The varying remoteness and magnitude of these worlds upon worlds define an interstellar perspective leading the eye in every direction, beyond "the Pillars of the Seven Planets," and beyond "the Towers of the Twelve Signs" of the Zodiac, on and on through endless vistas of glory into the very mystery of Infinity; and the mind, losing the sense of time, as measured by days and months and years, seems, by a transmutation overmastering all materiality and self-consciousness, to pass into the absolute, unconditioned, and perfect life and light of Eternity. These Vindhyan sunrises and sunsets also have their fulness of glory; and may be compared in their magnificence with those to be seen from Edinburgh Castle and Stirling Castle; but they have not the celestitude, and do not inspire the wonder, awe, and worship of the moonlit nights of Asirghar, ringing through all their sapphire depths with the angelic song of the *τρισάγιον*: "*Ἅγιος ὁ θεός, ἅγιος ἰσχυρός, ἅγιος ἀθάνατος.*"

Hill among Europeans, are the most conspicuous masses, crests, and peaks of the semicircular spur forming the southern watershed of the affluents, from the Malsaj *ghat*, the Tal *ghat*, and the Bor *ghat*, of the beautiful Ulhas or Kalyan [Callian] river, the principal river of the Northern Konkan; a corresponding semicircular spur is the southern watershed of the affluents, from the Bor *ghat* and the Sava *ghat*, of the Amba or Nagotna river, the most sylvan river of the Southern Konkan; and these two curved spurs, converging, from the north and south respectively, toward the west, before sinking out of sight, form the bright little archipelago of basalt islets, which, joined together by the clay deposits of the Kalyan and Nagotna rivers, and of the little Panvel and Patala-Ganga ["Infernal"—literally "Patent," *i.e.*, "Wide-mouthed"—"Ganges"] rivers, and by the shells and sand thrown up by the waves of the South-West Monsoon, constitute the compound island, lying like a natural breakwater in front of the common estuary of the four creeks of the Kolyan, Panvel, Patala-ganga and Nagotna rivers; and thus forming the magnificent harbour that has given its Portuguese name, and the commercial and naval control of the Indian Ocean, to the palatial city of Bombay;* rising from its bright green Esplanade, flush with the blue level of the Arabian Sea, like the apparition of another Venice, suffused with the richer golden light of the eternal sunshine of the East.

Beautiful indeed for situation is Bombay,—and for providential opportunity the joy and praise of all those whose business is in the salt deep! Among the palm groves, tufting the five basaltic monticules and mounds of the surrounding suburbs, sparkle the white walls of the houses of its opulent and luxurious merchant princes: this rare aggregation of natural and artificial features presenting a scene at once splendid, comfortable, and, in its encompassing alpine panorama, wonderful; and absolutely enchanting, when the blaze of day has set, and the silver moon hangs above all in the spacious silence of the clear midnight sky.

THE NORTHERN KONKAN.

There has always existed along the Ulhas, so far as it is navigable to sea-going craft, a great emporium of Oriental commerce, which, as this river became from age to age more and more silted up, gradually gravitated lower and lower down its course, from Kalyan, the Kalliana of the Greeks, in Buddhistic and later Brahmanical antiquity, to Thana, *i.e.*, Sthan, "the Settlement," in mediæval or Mahommedan times, and to the port of Bombay, its southern debouchure, in the modern, English period.

Bhiwindi, the Binda [*Benda*] of Ptolemy, five miles from the right bank of the Ulhas, opposite Kalyan, is thought to be an older Aryan mart than even the latter town, and was probably a primitive Vindhyan station; while the period of Portuguese supremacy in Western India is represented by Bassein, *i.e.*, Vassai, "the Settlement," at the extremity of the northern outlet of the Ulhas, which with its southern debouchure [and the sea], delimits a portion of the true mainland, the so-called "Island of Salsette," famous for its Buddhistic caves, dated between B.C. 100 and A.D. 50, at Kanheri. Chembur, two or three miles to the east of Mahim Causeway, joining Bombay to Salsette, and corresponding with the Portuguese town of Bandra west of Mahim, has been thought to be the Symulla [*Simulla*] of Ptolemy; but the latter is rather to be identified with Chaul, at the mouth of the Kundalika river in the Southern Konkan. Yet the white variety of the *pangri* (Erythrina indica] found by the ruined Hindu temple at this place,* and, in all the world, found only there, is to my mind a distinct relic of the ancient Buddhists, who, as their grove at Lanavla, beyond the Bor *ghat* shows, were enthusiastic aboriculturists. About ten miles north of Bassein is the common creek of the Tansa river, flowing from the Tal *ghat*, and of the sacred Vaitarna or Agashi river, the Goaris of Ptolemy, flowing from the Tal *ghat*, and the other *ghats* more to the north, which lead off, through their eastward gradients, the sources of the Godavari. About fifteen miles east from Bassein is the shallow and rapidly disappearing breakwater connecting the Ulhas or Kalyan river with the Vaitarna, and with them forming the spurious "Island of Sopara" or "Island of Agashi"; where yet stands the town of Sopara, the capital of the Konkans from B.C. 1500 to A.D. 1310. It is mentioned in the Mahabharata, under the name Shurparaka,

* The ultimate source of the name of Bombay is the temple of the tutelary island goddess Momba-Devi, "Our Lady of Bombay," an auspicious local form of the "Great Goddess" Devi, the consort of Siva.

* The discoverer of this tree was Mr. Bhasker, the *Karbhari* of the Victoria Gardens, Bombay, where I was careful to propagate innumerable cuttings from it, and to distribute them widely, even so far as Egypt.

and also in the Mahawanso of Ceylon, and is now justly held to be the Ophir of the Bible, spelt Sophir by Josephus, this form of the word still denoting India among the Copts of Egypt and Abyssinia. Without doubt it is the Soupara and Nousaripa of Ptolemy, placed by him between Nousaripa [Nosari], in the Baroda [Gaekwar] State and Symulla [Chaul] in the Southern Konkan. The well-known tope* here, was recently shown by Messrs. Mulock and Sinclair, of the Bombay Civil Service, to be a Buddhist relic mound, dating not later than A.D. 100, and one of the most interesting as yet excavated in India. The saintly associations of this tumulus probably account for the traditional sanctity of the "Island of Sopara" or "Agashi," not less than the origin of the Vaitarna in the same sacred summits of the Sahyadris with the deified "delimiting" [Tamil Goda], and "cattle-bearing" Godavari.

The Aryas must have been early attracted from Gujarat into the picturesque and gloriously umbrageous coast land of the Konkans; and it was by moving up the Konkan rivers, and scaling their innumerable *ghats*, excavated by the descending rivers, that they finally reached and civilised Maha-rashtra, rather than through the forbidding Vindhyan regions of Gondwana and Baglana. The Buddhistic remains at Kanheri and Sopara, and the imposing later Brahmanical sculptures on the little island of Elephanta, in Bombay Harbour, prove, by the great wealth lavished upon them, that all through antiquity, down to the rise of the Mahommedan power in Anterior Asia, the creeks and estuaries of the Konkans were everywhere the busy scenes of the immemorial trade carried on between the Persian Gulf, Red Sea, and Eastern Coast of Africa, and Western India. We witness it actually pictured for us on the contemporary wall paintings of the Buddhistic caves at Ajanta [B.C. 250—A.D. 250] at the extremity of the northern bifurcation, within the frontiers of the Nizam's Dominions, of the Chandor spur of the Sahyadris. The inland routes of this commerce from Kalyan over the Bor *ghat* into the valley of the Kistna; and from Sopara over the *ghat*, into the upper valley of the Godavari, and on to Plithana [Paithan, *Baithana* of Ptolemy] on the lower Godavari, and Tagara* [Daulatabad, the Hindu Deogiri], about 50 miles north of Plithana; where on the southern bifurcation of the Chandor hills, the sumptuous Buddhistic *viharas*,† and later Brahmanical pagodas ‡ at Ellura, as also the marvellous mural paintings at Ajanto, 50 miles north-east of Ellura, testify to the affluent resources of the ancient, pre-Mahommedan trade of Maha-rashtra at its eastern *termini*, as graphically as do Kanheri and Elephanta at its western starting-places in the Konkans. From Nasica [Nasik] a branch from this easterly trunk road turned more to the north, and crossing in succession the Chandor hills near Chandor, the Tapti river, the Sautpura mountains through the Sindhiva *ghat*, the Narbada river, and the Vindhya mountains over the Jam *ghat*, at last reached Ozene [Ujjain] and Sagida [the *Sagida* or *Sageda* of Ptolemy] in Malva. These ancient routes are to be traced not only where they begin and end, but throughout their course, by the remains of Buddhistic and later Brahmanical architecture, as at Karli in the Bor *ghat*, where there is the largest and best preserved rock-cut *chaitya*, or Buddhist memorial hall [church], hitherto discovered in India; and at Bhaja and Bedsa south of Karli; at Junnar north of Poona, and Nasik north of Junnar; and at Kolvi and Dumnar near Ujjain. And the great Buddhist topes at Bhilsa [Sanchi] and Bharhut, 125 and 325 miles, respectively, east of Ujjain, are also indications of the far extended prosperity of the ancient trade of Maha-rashtra, rather than of the separate commercial system of the alluvial valley of the Ganges, cut off as the latter is from the lofty plains of the Godavari and the Kistna by the

* This Anglo-Indian word has a double derivation, viz., from the Sanskrit *stupa*, "a tumulus," as here: and the Canarese *topu*, "a clump of trees," as here also; the tope at Sopara having been so called by both Europeans and natives, from the vegetation on it, chiefly *karanda* bushes [Carissa Carandas], long before it was recognised, and first by Mr. Mulock, as a Buddhist mound.

* Tagara has also been identified with Deogiri, at the mouth of the Deogiri river, in the Ratnagiri District of the Southern Konkan, and the natural seaport of the Kolhapur State; while Mr. T. F. Fleet, of the Bombay Civil Service, identifies Tagara with the town Kolhapur itself, one of his arguments being that the *tagara* [*Tabernæmontana coronaria*] grows freely in its neighbourhood. There is a town called Tegur, a few miles N.E. of Dharwar.

† *Vihara* is a Sanskrit word meaning a Buddhist convent, and is traced in the name of the Province of Behar, in the Lieutenant-Governorship of Bengal; of the village on the Island of Salsette, near the great reservoir of the Bombay Waterworks; and, according to Colonel Yule [*Hobson-Jobson*], of the city of Bokhara in Central Asia.

‡ The Anglo-Indian word "pagoda," has also, like "tope," a double derivation, viz., from the Sanskrit *dhatu-garbha* "relic receptacle" [literally "tooth-womb"], though the Cyngalese *dagaba*; and from the Portuguese *pagao*, "a pagan." In India, however, the word "pagoda" is always applied to the idol-temples of the Hindus, and the word "tope" to the relic-mound of the Buddhists. The "pagodas" of China and Burma are Buddhist temples built [nominally] in seven stories.

defiles of the Jumna; which from opposite Delhi to opposite Allahabad and Benares, form the northern escarpment of the triangular trappean and granitic table-land of peninsular India. The beds of the Son and Narbada, forming a continuous waterway, sloping in opposite directions, from Patna [Palimbothra, *i.e.*, Pataliputra] on the Ganges to Broach [Barygaza] at the mouth of the Narbada, seem to open out a thousand miles of direct inland communication, through the very heart of Gondwana, between Northern and Southern India; but so inaccessible are the Amarkantaka highlands, in which these rivers, and the Mahanadi, the river of Orissa, have their common source, and so precipitous is the channel of the Narbada, and so intricate that of the Son before it reaches the plain of the Ganges, that these rivers, so far from serving to overcome, rather aggravate the obstructions placed by the Vindhya and the Satpura mountains to free intercourse between Hindustan and the Dakhan.

The strange admixture of religious ideas and practices current among the Mahrattas is only to be satisfactorily explained by the enlarged commercial intercourse with Anterior Asia, and Egypt, and the West, enjoyed by Western India all through the great Buddhistic millennium from B.C. 500 to A.D. 500. That commerce made Buddhism in the East, as, through Buddhism, it made Christianity in the West; while in Maha-rashtra, to the deeply-rooted and strongly infectious animism of the Vindhyan aborigines, and the Vedic polytheism of the Aryan settlers, it added the elements of Chaldæan sabaism, Egyptian asceticism, Roman stoicism, and some of the distinctive principles of that general humanitarianism of the period which at last found its highest expression in Christianity. Even Bible names are surmised to have been deified among the Mahrattas, who near Pandharpur worship an image called Bawa-Adam, and in the Berars another known as Jabral-Abral [? the Angel Gabriel]. I am satisfied that the glory of the legendary Hindu rajah Vikramaditya [of Ujjain] of this period, is in part the reflected glory of Augustus Cæsar; and that "the Nine Gems" of Vikramadityas Court are none other than Virgil, Horace, Ovid, and rest of the Augustan poets.

It was, in all probability, in the course of this secular trade between the East and West, and long before it became so intimate as it did between the dates of Alexander the Great and Justinian I., that the characteristic Mahratta drill ploughs, the *moghar* and *pabhar* were introduced into Western India direct from Chaldæa.

The Southern Konkan.

Janjira, at the mouth of the romantic Rajpuri creek, below Chaul, in the Southern Konkan, is supposed to be the Sigerus of the Greeks and Romans, and Mhasla, at the head of the creek, the Mousopalle of Ptolemy. Below Jinjira are Bankot, at the mouth of the Savitri river, flowing from Mahabaleshwar, and Dabhol, at the mouth of the Vashishti, both places of some trade in the Mahommedan or mediæval period; Ratnagiri, at the mouth of the Bhatya; Deogiri or Devgad, absurdly identified by some with the ancient Tagara; Malvan, at the mouth of the Kalavli, where the trappean formation is last seen in the Konkan; and Vengurla, where the gneissic series of Southern India first makes itself prominent on the Malabar Coast. None of these exiguous ports ever accommodated anything more than a precarious local trade, and being thus inaccessible to the international trade of antiquity, the narrow alpine strip of the Konkans between Chaul and Goa was never fully brought under its denationalising influences, and remained all through the thousand years of the predominance of Buddhism in Hindustan,—and in the Dakkan so far south as the left bank of the lower Kistna,—a safe refuge for the families of the conservative Aryan priesthood now known as the Konkanast Brahmans. The Brahmans of the Ganges valley affect to despise them, and in their disdainful and despiteful ignorance apply literally to them the traditional cognomen they bear of *Chitpavan*, *i.e.*, "a corpse saved from the funeral pyre," a figurative epithet probably condensing in a word the long history of their almost miraculous survival from the fire of Buddhistic persecution. But whatever may be the interpretation of the local legend of their origin, they are a well-grown, handsome race of men, with fair complexions, light gray eyes, and strikingly intellectual faces, and obviously of far purer Aryan blood than any other Hindu people east of the Gandak and Son, or south of the Kistna: and above all else, they present, in their manly and joyous national temperament, a complete moral antithesis to the witty and plaintive Bengalee Babus, a radically Turanian race. Such being their inherent aristocratic characteristics, it is not surprising that, on the collapse of Buddhism, and during the decline of the Mahommedan

power in India, emerging from their secure retreat in the Southern Konkan, they gradually, as of natural right, gathered into their masterful hands the whole administrative, political and social, control of the Mahratta nationality, and, from the Peshwar downwards, became the first and foremost personages throughout the Dakhan. Their mental superiority is shown by the manner in which their historic family names crowd the honours-lists of the Bombay University.

The *Chit-pavan* women are of the most refined type of feminine loveliness; and in the sweetness, grace, and dignity of their high-bred beauty, at once modern in its delicacy, and antique in its fearless freedom, they might well be taken for the Greek originals of the Tanagra "figurines," awaked to a later life among the tropical gardens and orchards and cocoanut groves of the Southern Konkan. One never wearies of watching them, as they are to be seen in the dewy morning in their gardens, perambulating, in archaic worship, the altar of Holy Basil [*tulsi*, Oocymum sanctum] placed before every Hindu house; or of an afternoon as they pass, in fetching water, to and from the near riverside, or the lotus-laden tank of the village temple, all in their flowing robes of cotton, of unbleached white, or dyed a single colour, pink, scarlet, black, green, or primrose yellow, presenting as they move, in the deepening shadows of the trees, along the red laterite roads, fitfully illumined from across the blue sea by the sidelong glances from the declining sun, the richest chromatic effects, in all the bright glamour of a glowing Turner or a Claude. And the outward and visible charms of these fair *Chit-pavnis* faithfully mirror the innate virtues of their pure and gentle natures; for they are perfect daughters, and perfect wives, and perfect mothers, after the severely disciplined, self-sacrificing, Hindu ideal, the ideal also of Solomon and Sophocles, and of St. Paul and St. Augustine, remaining modestly at home, as the proper sphere of their duties, unknown beyond their families, and seeking in the happiness of their children their greatest pleasure, and in the reverence of their husbands the amaranthine* crown of a true woman's glory in the highest.

THE KONKAN-GHAT-MATHA.

The ascent from the Konkans to the summits of the Sahyadris, or *Konkan-ghat-matha** ("Konkan-pass-top"), is very rapid. The old military road up the Bor *ghat* rises six hundred feet in a mile; and the Tal *ghat* is as steep. In order, therefore, to carry the railway from Bombay to Nagpur and Benares over the Tal *ghat*, and to Madras over the Bor *ghat*, the engineers had to take advantage, at the farthest possible distance from these passes, of the shoulders projecting from the main axis of the Sahyadris towards the Island of Bombay. In this way, along the Tal *ghat* incline, half the ascent is almost unconsciously overcome, and the final lift on to the plateau of the Dakhan is made, with comparative ease. The Bor *ghat* railway incline is almost fifteen miles in length, and its average gradient is one foot in forty-eight; the work consisting of a series of Cyclopean cuttings, tunnels, embankments, and viaducts, carried through and over some of the finest scenery in the world. Thus, starting at a wide distance from the military road, the railway line runs straight up until it joins the former at the old Toll House on the west side of a gorge, surmounted on its opposite or eastern side by the perpendicular precipice of "The Duke's Nose;" and from this point, where a Reversing Station stands, 1,548 feet above the sea, it doubles back, with the military road, to the village of Khandala, 1,786 feet above the sea, and continues its course past the ancient Buddhistic grove at Lanavla, 2,030 feet above the sea, and thence, down gradually descending gradients, on to Poona and Sholopur, and to Bellary and Madras.

The slope of the trappean formation of Maha-rashtra is very gradual from the Sahyadris towards the Coromandel coast, and these mountains, therefore, present on their eastern side very long spurs, sinking slowly into the general level of the Dakhan; but in starting from the same culminating headlands of the axial range, the eastward spurs, so far correspond symmetrically with those on the west. Thus, about sixty miles south from the Chandor, or Ajanta and Ellura, hills, the Ahmaduagar hills start from the mountainous mass of Harichandragar, rising 3,894 feet above the sea, and having a fort with walls 18 miles in circumference on its summit. Thence they run in a ridge on to Brahmanvara, where they are 2,866 feet in height, and then expand into a terraced tableland, twenty-four miles long,

* All-a-down the delectable Malabar Coast the women wear the flowers of the Globe Amaranth (*Gomphrena globosa*), cultivated in every garden, in their hair. Compare 1 Peter v. 4; and 1 Cor. ix. 25.

* Often spoken of simply as *Bala-ghat*, "the country Above-the-passes." *Desh*, literally "country," is the general plain beyond the *mavals*.

wenty broad, and from 2,474 to 2,133 feet high, at Ahmadnagar; whence they are continued southward, until they disappear in the neighbourhood of Sholapur and Nuldrug. A short secondary spur, jutting out from them close to their connection with Harichandragar, ends, west of Junnar, in the rugged rock of Shivnar, rising 1,000 feet above the surrounding plain; and the fort at its top was the birthplace of Sivaji. The famous temple of Bhimashankar, on the crest of the Sahyadris, 3,000 feet above the sea, midway between Harichandragar and Khandala, marks the sacred source of the Bhima, which, with its northern affluents, drains all the rich, fertile dale between the Chandor and the Poona hills.

Sivaji's Strongholds.*

The Poona hills originate in the territory [*jaghir*] of the Pant Sacheo of Bor, in a maze of spurs, merging in the course of ten or twelve miles in the spur that stretches south of Poona, separating the strath of the northern affluents of the Bhima from the dale of the Nira, the main affluent of the Bhima from the south. Close to the Sahyadris stands out boldly, to the height of 4,605 feet, the hill fort of Torna [cf. *tortus*, and torque, torch, torture, tart, &c.], so called from the contorted, or twisted, pinnacle of basalt, that marks its position from afar. It was here that Sivaji hoarded the booty gathered in his earliest forages. Immediately south of it is the hill, 3,392 feet high, that Sivaji, on finding Torna insufficiently secure against a surprise, fortified, and re-named "Raj-gar, "The Citadel of the Kingdom." About twelve miles west of Torna and Raj-gar is the hill fort originally called Kondhana, but re-named by Sivaji after he had captured it, Sinhgar, "The Lion's Den." Rising from 4,162 to 4,322 feet above the sea, and 2,300 feet above the plains below, it commands toward the north the whole vale of the Muta Mula, from the rich, evergreen forests [chiefly of Memecylon edule, and Carissa Carandas] about Khandala, to the open arable country, wherethrough, on the extreme east, the Muta Mula reaches the Bhima. In the middle ground, under the dominating hill temple of the "Great Goddess" Devi, in her name of Parvati, "The Mountaineer," the red-tiled roofs, and gaily painted house walls of Poona stretch hither and thither amid the deep verdure and towering foliage of the *agar* [cf. "ager"], or broad tract of enclosed orchards and gardens, and groves, and avenues of richly grown forest trees [*nimb*, Azadirachta indica, *pipal*, Ficus religiosa, and *bur*, Ficus indica] within which the fairest city of the Dakhan, the Damascus of India, lies far and wide embosomed. From the south, Sinhgar looks down upon the narrow, lovely valley of the Nira; but it is best seen from Sivaji's proud hill fort of Purandhar, 7 miles south-west of Sinhgar, standing 4,472 feet above the sea, and 2,566 feet above the plains of Poona, with the sparkling Nira flowing past its base, almost due south-eastward, for 70 miles, to the Bhima. On the right bank of the sunny Nira stands the sacred town of Jejuri, famous for its majestically-situated fane of Khandoba or Khanderao, a national incarnation of Siva, in the figure of an armed horseman, and, next to Vithoba or Vithal, the most popular object of worship throughout Maha-rashtra. Attached to his temple is a large establishment of dancing girls [*deva-dasi*, ἱεροδούλαι, ἑταίραι] Not far from the temple, and close to Nira bridge, is the village of Valhe, the reputed birthplace of Valmiki,* the legendary author of the divine *Ramayna*. In this valley also is Hol, the native village of the first Holkar. About 11 miles below the confluence of the Nira with the Bhima is the handsome city of Pandharpur, esteemed so holy, owing to the presence of the great temple of Vithoba, the national incarnation of [Krishna-] Vishnu, that the rich land immediately round it is restricted to the cultivation of the sacred *tulsi* plant, Ocymum sanctum, famed throughout India for its refreshing and sanative fragrance. It was the custom of all the principal members of the Mahratta Confederacy, the Peshwar, the Sindhia, and the Holkar, to keep up a house in this town; and here it was that the Gaekwar's ambassador, Gangadhar Shastri, was foully murdered in 1815, at the instigation of the degraded Baji Rao Peshwar, by the hired assassins of Trimbakji Danglia.†

* For a complete list of Sivaji's 145 fortresses, of which 89 still remain in the possession of the Mahratta Princes, see "Sivaji's Swarajya," a paper read before the Bombay Branch Royal Asiatic Society, 17th December, 1903, by P. V. Mawjee. J.P.

* See *The Triumph of Valmiki*, translated from the Bengali of H. P. Shastri, M.A., by R. B. Sen, B L., Chittagong College, 1909.

† Together with the names of the Hindu gods, and such titular names as the Peshwar, the Holkar, the Sindhia, the names of Gangadhar Shastri, and Trimbakji Danglia, were the most familiarly impressed on me from my earliest infancy in India, 1832-9; and Trimbakji Danglia's, with the vividness of that of a popular hero still actually alive; as for generations after their deaths the names of Robin Hood and Rob

About 60 miles due east from the junction of Nira with the Bhima, is the third sacred city of the Mahrattas proper, Tuljapur, an open town in the Nizam's dominions, containing numerous temples dedicated to Bhairava, a lower national incarnation of Siva than Khanderao or Kandoba. To the south and west of Purandhar the horizon is closed in by the Mahadeo or Satara hills and the Sahadri mountains, and beyond and above the latter, 44 miles due west of Purandhar, rises out of the Konkan, 2,851 feet above the sea, the hill fort formerly called Rai-ri, in Sanskrit Raygiri, "the Royal Hill," but named by Sivaji Raygar, "the Royal Fort." It is the strongest of his forts, "the Gibraltar of the East," where Sivaji held his coronation, in 1674, and died in 1680.

The Grave of Sivaji.

The scandent Bougainvilleia spectabilis irradiates with the exotic splendour of its loose waving tresses of majenta - coloured bloom the stately marble cenotaph of Akbar at Sikandra near Agra, a befitting emblem of the magnificence of the alien rule of the Mo(n)gols in India. As aptly, and yet more remarkably, because quite fortuitously, the grave of Sivaji, on the top of Ray-gar, is now to be traced only by the patch of one of the commonest wild flowers of Maha-rashtra growing over it, the Commelina communis, its exquisite bright blue petals reflecting back year after year the azure of the skies above, as if in sign of the great national leader's eternal peace with heaven.

"Poor Nellie's" Grave.

Another notable grave on these mountain tops is that of the botanist, John Graham, who died in 1839 at Khandala, and was buried there behind the Travellers' Bungalow, at the extremity of the grassy platform, thickly studded with the pretty white-flowered terrestrial orchid, Habenaria platifolia, overlooking the Khandala ravine; the spot being indicated by a short obelisk. South-west of the village of Khandala, beyond the barracks, in the old military cemetery on the slope of "Carnac Point," close under the "Duke's Nose," there stood 33 years [now 53] ago, out of the thick sward of the dark blue and white magpie-flowered Exacum bicolor, a headstone labelled simply "Poor Nellie," marking the grave of some English soldier's young wife, and hallowing all the hills around by the associations of its tender and heroic pathos.*

Mahabaleshwar.

The Satara hills project 100 miles eastward from Mahabalshwar, and from this main spur send off, toward the south-east, three subsidiary spurs, each about 50 miles long; the first,—running at a distance of from 5 to 10 miles from the Sahyadris,—separating the long, narrow dale of the Koyna, the west-most affluent of the Kistna, from the broad vale of the head stream of the Kistna, and of the Yerla, the largest of the direct eastern feeders of the Kistna within the Satara district; the second separating this vale from the valley of the Man or Man-ganga, a tributary of the Bhima; and the third separating the Man valley from the wide strath of the Bhima, which river receives the Man about 50 miles below the influence of the Nira, and after receiving the Sina from the east, about 25 miles south of the influence of the Man, itself becomes confluent, 100 miles farther south, with the main, eastward-flowing stream of the Kistna.

The head stream of the Kistna, with the Koyna, and the Yenna, a small tributary of the Kistna, all have their head springs in Mahabaleshwar, as also have the westward flowing streams ot the Savitri and Gayatri; and these five rivers, with the sacred Ganges, feigned by the Brahmans to derive a source, every fifth year, from Mahabaleshwar, are known to the hill-men of the locality as "The Six Sisters."

The Brahmans in charge of the temple of Krishnabai, "the Lady Krishna," at the head of the "Kistna Ravine," show you five rills of water running through five holes in the west wall of the temple, into a small tank, held of the highest sanctity, from which their collected waters flow through a carved stone cow into a second tank of lesser sanctity, and thence tumble down the steep side of the ravine into the Kistna; and they tell you that these five rills are the secret fountains of the rivers

Roy lived on in the memories of Englishmen and Scots. Bishop Heber's lines on his romantic escape out of our hands from the fort at Thana, in "the Island of Salsette," are well known :—

"Behind the bush the foemen hide,
The horse beneath the tree:
Where shall I find a knight will ride
The jungle paths with me?

"There are five and fifty couriers there
And four and fifty men;
When the fifty fifth shall mount his steed
The Dakhan lives again."

* I deeply regret that on inquiring after it, on reading the announcement of the publication, by the author of "My Trivial Life," of the novel entitled "Poor Nellie," I found that this touching tombstone has now [1888] disappeared.

Kistna, Koyna, Yenna, Gayatri, and Savitri; and as every drop of rain that falls on Mahabaleshwar, and every square foot of its oozy sward, may be said to be the common source of all the rivers flowing from it, the pious fantasy of these Brahmans is not to be lightly gainsaid. But in profane fact, even the Kistna itself rises a mile or two to the left of the temple among the runnels, formed by the superfluous drainage from the hill, below Arthur's Seat [Malet Point], the northmost point of Mahabaleshwar, and the water-parting between the Kistna and the Savitri, or river of Bankot. A south-westerly projection from Arthur's Seat, called Elphinstone Point, forms the water-parting between the Savitri and the Koyna, the latter winding past Lodwick Point, and Bombay Point, and Babbington Point, all on the west side of the Mahabaleshwar plateau, before continuing its south-easterly course inland, toward the Kistna. Babbington Point looks right down the long, green fairy-like dale of the Koyna, dotted throughout its length, along the course of its perennial river, with groves of tall trees, mango [Mangifera indica], jack [Artocarpus integrifolia], and *jambul* [Sizygium Jambolanum], and, towards the open plain of the Dakhan, *babul* [Acacia arabica], all indicating the sites of the hamlets and little villages, nestled within them, of the patient and skilful Mahratta cultivators, who have everywhere in these retired valleys carried the tillage of the *mavals* to the highest perfection.

From the temple of "The Lady Krishna," or from Kate's Point, three miles to the right, the valley of the Kistna opens out to the right, past Wai, and Satara, and Kurar, a gradually widening view of the plain of the Dakhan and its far-extended and ampler agriculture. But as both the summits and the escarpments of the hills on either side, as seen end on, present an unbroken outline, the prospect lacks variety; and only the vast magnitude of its scale, particularly in the immediate foreground, lends a sublime sternness to its severe monotony. Yet, visited in the still moonlight, and looked at from the Krishnabai temple, down on the sacred town of Wai, with its clusters of superbly sculptured shrines, as one yields sympathetically to the associations of the locality, the scene is one that makes an indelible impression on the memory.

From Arthur's Seat north-westward, across the dense forest that shelters the sources of the Kistna, extends the main axis of the Sahyadris; their blackened, trackless gorges, and bluffs of stratified basalt, stratum upon stratum, high uplifted to the zenith, and gigantic stacks of serried peaks, presenting, as thus viewed fore-shortened, a boundless prospect of the wildest desolation.

Lodwick Point is a narrow wall of basalt, not more than from 6 to 12 feet broad towards its extremity, running out 10,000 feet into the west, and there dropping down suddenly 2,500 feet into the valley of the Koyna below. The drop is so perpendicular that a runaway horse I once saw leap at full gallop from the Point fell dead at its base without striking against any salient ledge or angle in the fall. Projecting out into the sky, almost like a bowsprit from a ship, it commands a lofty perspective of the Konkans, in front of the main axis of the Sahyadris; but the predominant feature in the landscape here is the point itself, rearing its colossal wall, like a horse's neck thrown up inquiringly, above the deep, beautifully-wooded ravines of the Koyna on either side of it.

Bombay Point is so called from its having been there that the plateau of Mahabaleshwar was first reached by the old road from Bombay up the "Rotunda Ghaut."* It is a large space cleared out of a wood of noble evergreen trees, and fenced in, above the Rotunda Pass, by a low parapet, overgrown with Clematis wightiana [*murvail*], Hoya viridiflora [*hirandori*], the sweet-scented, white-flowered Jasminum latifolium [*kusur*], Embelia Basaal [*ambut*], and other luxuriant creepers and scandent shrubs. The view from it is the most extensive and varied and the most interesting on the hill; and hence this green, cool, and fragrant spot has become the general resort, of an afternoon, toward sundown, of the English families residing during the "hot season" at Mahabaleshwar. It is evergreen-wooded to its base, in the sweet valley of the Koyna, west of which the rugged, craggy spurs of the Sahyadris, stretching across the Konkans, present an infinite diversity of picturesque contours, spur beyond spur, without end, toward the north and south, and only bounded on the west by the glittering horizon of the Arabian Sea. It is said that sometimes a glimpse may be obtained beyond the long sylvan valley of the Nagotna river of Bombay, 100 miles distant; while southward the coast can be followed to Ratnagiri.

In the middle ground the low saddle-backed

---

* That is, *Rortundi-ghat*, "the Roaring [or Crying] Pass," so called from the difficulty of its ascent; and the groans of the palanquin-bearers who carry you up it.

ridge, dipping down from Elphinstone Point, and forming the western enclosure of the Koyna valley at its head, suddenly ascends, before dipping down again to the Par* *ghat*, in Sivaji's massive flat-topped hill fort of Pratabgar. Only four miles distant, and rising by steep grassy slopes to an altitude of 3,543 feet above the Arabian Sea, distinctly visible on the left, it stands out boldly against the blue sky, directly in front of Bombay Point, and in strong contrast, when, after mid-day, its whole eastward side is in shade, with the bright, shining heights of the Konkans beyond. As the rays of the afternoon sun begin gradually to strike more and more horizontally through the heated, rarified mists drawn up by it during the forenoon, the natural complexion of this majestic scene undergoes a series of atmospheric transfigurations of indescribable splendour. At first the hills and dales of the Konkans seem to be suddenly transmuted into into silver, shining, as with its own light, in dazzling brightness along the ridges of the hills, but with a softer lustre in the dales, where their ethereal illumination is subdued by the lengthening shadows thrown by the sinking sun. Again, in the twinkling of an eye, all is changed to radiant gold, clear as topaz on the hill-tops, with the sea on the left ruled in long levelled lines of chrysolite; and when the day closes upon the eastern hemisphere, the rapidly falling mists pass from a glowing purple to dense indigo, and the cleared sky at last reflects back from the darkened landscape the deep transparent sapphire colour that is the proper tincture of an Indian night.

Mahratta Patriotism.

Before natural scenery of such spiritual expression and significance men have ever recognised that this outspread green earth, with the revolving circle of the sun and moon and stars above, is but the marvellous contexture of the veil dividing the world we see from the unseen, inscrutable life beyond: and inhabiting a country at once of great grandeur and loveliness, and of the strongest individuality of natural features and phenomena, the Hindus in general, and particularly the Mahrattas, have marked every hill and dale and river, and almost every "kenspeckle" tree and stone throughout India, by a shrine, altar, towering temple, or lone uncouth image, in acknowledgment of the felt presidence of the one polyonymous God of universal human worship; who is everywhere identified by some dramatic name, accurately descriptive of the most characteristic local manifestation of His might, majesty, and all pervading presence. Barren, scorched plains, and pestilential marsh-lands, and blackened, lightning-riven mountains are identified with Siva in some one of his higher or lower incarnations; and fertile tracts, and pleasurable prospects with Vishnu or Krishna; or with Siva's consort, "the Great Goddess," Devi, in her more auspicious aspects, such as Parvati, "the Mountaineer," Gauri, "the Yellow-haired," "Uma," "the Wanton," and "Jagan-mata," "the World Mother." Again, the money-making classes have for their tutelary divinities Vishnu, and his consort, the fair Laksmi, also called Loka-mata, "the World Mother;" while the ruling classes, whose duty it is to be "untender-hearted" [ἀμείλιχον ἦτορ ἔχων] worship Siva, and his consort Devi as Bhavani [Ἀθηνᾶ Πολιάς]. The armed horseman, Khanderao, is the historical Mahratta manifestation of the Godhead. The higher class of agriculturists are the devotees of Krishna and his loose lady-loves; while the favourite divinity of the lower class of agriculturists all through Maha-rashtra, and of all men in their less serious moods, is the playful monkey-god Hanuman, *i.e.*, "Long-jaw" or "the Prognathous One."

Thus throughout the length and breadth of the Konkans and the *mavals*, as surveyed from Bombay Point, from every height and depth there goes up the joyous salutation:

> "Thou art, O God, the Life and Light
> Of all this wondrous World we see!"

In everything the Mahratta finds God; the stones discourse of Him, the running brooks are His life-giving word,* every tree is a tongue in His praise, and every flower an Alleluia! This is the simple explanation of the intensity, the downright fanaticism, of the patriotism of the Mahrattas. Maha-rashta is not merely their mother country, but also their heavenly inheritance; while the presence of the Mahommedans, as religious persecutors, was regarded, not merely as a foreign intrusion, about which of itself they would have been very

* That is, "the Village," *par* or *para* being the Mahratti for "village" or "hamlet," but meaning literally "altar;" that is, the altar thrown up about the *pipal* [Ficus religiosa] or *bur*, or "banyan tree" [F. indica], round which every village or hamlet in India is built, and the village assemblies are held. *Par-ganah*, a revenue circle of many villages, is literally "the collection ["gang" of, Gana-pati, "Lord of Hosts"] of altars."

* A saying attributed to Mahomet.

indifferent, but as an absolute profanation and sacrilege, to be expiated at any cost.

Of all Europeans, the Scots are probably the most fervent in their patriotism; but Scotland after all is no more than their native country,—since the Reformation robbed them of their tutelary saints. It is not their Holy Land, where God has walked with man, which for them, as for all Protestant Christians, is far away in Jewry. To judge therefore of the Mahratta feeling for home and country, we have to conceive what perfervid Scotch patriotism would be, were Kishon a Scottish brook like Bannockburn; and evergreen Carmel, and Mount Gilboa, and Tabor and Hermon, spurs of the Cheviots, or the Lammermuir Hills; and the fragrant valley of Sharon, and the plain of Jezreel, "the seed plot of God," tracts of Tweeddale or Clydesdale; or were Flodden Field also the fateful field of Megiddon, as in sense it was, or,

"—— stately Edinborough, throned on craggs"

one with Jerusalem "the Golden."

"Thy terrettes and thy pinacles
With carbuncles doe shine.
Thy verie streetes are pauved with gold
Surpassinge cleare and fine.

Those statelie buildings manifold
In squares and streetes doe rise,
With gardens deckt, and lofty fanes
Eenclosed Castle-wise.

Quyt through the streetes with siluer sound
The Flood of Life doth flowe,
Upon whose bankes on everie syde
The Wood of Life doth growe.

There Magdalene hath left her mone
And cheerfullie doth singe
With blessed Saintes whose harmonie
In everie streete doth ringe."

THE APOTHEOSIS OF SIVAJI.

And it is in this conception of the Mahratta character that the foul and treacherous murder of Azful Khan by Sivaji at Pratabgar, must be estimated. From Bombay Point you can distinctly see the temple of Bhavani, in which Sivaji, Siva's son, solemnly dedicated himself to the terrible act, and the gateway in the circumvallation of the frowning fortress through which he walked down to meet the chivalrous, unsuspecting Bijapur general at the fatal trysting-place, to which the latter, with only a single attendant, walked up from the Koyna valley; and the very spot where he was so vilely assassinated, and where his body lies buried, is conspicuously indicated by an evergreen shrub [*apta*, Bauhinia racemosa], standing solitary on the hillside. The deed was damnable; but Sivaji, in all truth and sincerity, deemed it high and worthy, and the last sacrifice of his devout patriotism to the welfare of his sacro-sanct country; and it will be a bad sign for the Mahratta people if they ever come to think less of Sivaji for it. The Bijapur army lay between him and the independence of his country, and the only way in his power for destroying it was by the destruction of its commander, and hardening his heart to the necessity, he enticed his noble victim into an ambush, and in a paroxysm of sacramental ecstasy determinately slew him.

THE BOTANICAL WONDERS OF THE SAHYADRIS.

The Kolhapur hills start from the hill fort of Vishalgar,* 3,350 feet high, whence Sivaji made his incredible night raid on Mulhol, on the Ghat-prabha, 150 miles distant; and from Vishalgar they extend for about 45 miles eastward, being crowned near their extremity by the hill fort of Panhala, the last of the seven greater strongholds of Sivaji in the Mahratta country, where a dozen others of lesser note might be named. These hills are the waterparting between the Varna—forming, from its source up to its confluence with the Kistna at Miraj, the frontier between the District of Satara and the Kolhapur State,—and the Panch-ganga or Kolhapur river; and they are the only range of the confused mass of hills covering the Kolhapur district that runs out over the plateau of the Dakhan at right angles to the Syhadris. All the shorter spurs to the south of it run at a more or less acute angle toward the north, carrying northward the three terrestrial tributaries of the Panch-ganga,† which reaches the Kistna half-way between Miraj and Erur-Manjira; the point where the Kistna is joined from the south by the united streams of the Dudh-ganga, Ved-ganga, and Hiranya-keshi. Beyond Mudhol the Kistna is swollen by the Ghat-prabha, flowing almost due west from the Ram *ghat*, almost coincidently with the line of division between the trappean and the granitic Dakhan, and forming the natural boundary between Maha-rashtra and Karnataka.

The highest pleasures afforded by the scenery of the Sahyadris are for the botanist, and the flora of these mountains shows in its fullest glory in the Kolapur region between Vishalgar and the Ram *ghat*, the great pass.

* There is another Vishalgar fortress in the Thana District and a Vishalgar pass, or *ghat*, in the Ratnagiri district.

† The fifth tributary, constituting it "the Five-Ganges," is the celestial Sarasvati.

just beyond the Kolhapur frontier, between the shores of the Arabian Sea at Vengurla and Goa and the plateau of the Dakhan. I shall never forget my first vision of the Bombax Malabaricum, or "Red Silk Cotton Tree," in the Ram *ghat*.

I had left the plain below about 2 a.m., in medical charge of a party of about 250 European troops, and after a slow ascent of some hours, suddenly, at a turn of the road, just at sunrise, came out upon a glassy glade, overhanging the profound forest depths below, and there, at its farther edge, stood a colossal specimen of this tree, quite fifty feet high, the trunk straight as "the mast of some great ammiral," deeply buttressed at its base, and sending out horizontal branches, like the yard-arms of a ship, in whorls of five and seven, gradually tapering to the top, and at this season, the month of March, leafless, but covered on every branch, in place of green leaves, with huge crimson* flowers, each from seven to five inches in diameter, and forming in the mass a vast dome-like, symmetrical, head, that, with the beams of the rising sun striking through it, shone in its splendour of celestial, rosy red like a mountain of rubies. I fairly shrieked with delight at the sight of it, and galloped off at once toward it, followed in a rush by the whole column of men, who were mostly recruits, fresh from England like myself, and at last, by the young officer in command, who, on taking in the whole situation, a most picturesque one—the red coats swarming over the green grass up to the resplendent tree—from where he had stood in momentary astonishment at so unexpected a breach of discipline, after administering a kindly rebuke to myself, left us to sit on for awhile, worshipping in its ruby tinted light, before continuing our march to the top of the *ghat*. Again, when I first saw the Hoya vividiflora, "all a growing, all a blowing," in its natural state, on the lower slopes of Prabhul, opposite Matheran, before I knew what I was doing, I was off my pony, turning "cart wheels" round and round this mystically green-flowered scandent shrub. I could particularize many individual specimens of different gorgeously flowered species of forest trees, such as the golden yellow flowered Cassia Fistula [*bava*], the purple flowered Lagestrœmia reginæ [*taman*], the vermilion and chrome yellow flowered Butea frondosa [*pulas*], and the scarlet Erythrina indica [*pangri*], that, on account of their stately development, and the striking situations occupied by them at Matharan, Khandala, Mahabaleshwar, and the Ram *ghat*, are each one of them worthy, during the months of their glory, of a visit from England. For the present I may do no more than note, as an indirect proof of the great botanical charm of the whole region of the *Konkan-ghatmahta*, and the *mavals*, and of its recognition by the Mahrattas, that the Kolhapur State still bears its ancient name of Karavira [*Sirkar Karvir* in the vernacular], "the Oleander [-land]"; and that the white-flowered, fragrant dog-bane, Tabernæmontana coronaria, which, with the Nerium odorum, is found throughout the upper valleys of the affluents of the Kistna, probably gave its native name, as suggested by Mr. Fleet, to Tagara, whether we identify that ancient Indian city with Daulatabad in the Nizam's Dominions, or with the city of Kolhapur, "the Lotus-city," itself. At every turn in the *mavals*, the wayfarer comes on the bed of some mountain stream, tufted all along its banks, and all over the little green eyots amidst its waste of pebbles, with mixed sweet scented oleander and tamarisk, carrying the beholder back at once to the Ilissus, and the slopes of Mount Hymettus. The lovely blushing oleanders are always found to shade some pure, clear pool left by the river from its summer flood, at which the gentle maidens, and comely matrons, from the near village are filling their water-jars,—

> "a group that's quite antique
> Draped lightly, loving, natural, and Greek,"

as in the painting of the Rogers' vase of the women of Athens filling their pitchers at the fair flowing fountains of Callirrhoe.

The Plain of the Dakhan.

The central plateau of the Dakhan, or *desh* [*i.e.*, "[plain]- country"], as it is called by the natives, [in contradistinction to the *bala-ghat* or *ghat-matha*] eastward of the *mavals*, from Mudhol and Kaladghi on the Ghatprabha, northward past Bijapur, and past Sholapur along the Sena, to Ahmadnagar, and north-westward past Pandharpur and Indapur on the Bhima, and on toward Poona and Junnar, is an open plain, rising and falling in prolonged tame lines, the ground swell, as it were, of the boundless ocean of trap flowing over it. Solitary *turwur* [Cassia auriculata]

* By reflected light deep crimson; by transmitted, the radiant red of a ruby.

and *babul** [Acacia arabica] trees, and rare clumps of date palms, diversify it, and multitudes of mud-walled villages, the positions of which are shown in the landscape by lofty "topes" rising amid black ploughed fields, and breadths of corn and pulse and other crops, waving dark green over the wide arable expanse, save where interveined with the vivid verdure of the rice fields following the courses of the river beds. Some of these trap waves are mere mounds of trap rock, covered with a rusty-looking rubble called *mohrum*, its first debris. Others of greater amplitude are covered with black or brown soils, patched here and there with deep violet or jasper red, all more or less advanced stages in the decomposition of the same trappean debris. Earths similarly diversified fill up the intermediate troughs in the undulating champaign. The hard surface of the exposed trap is scarred with innumerable runnels, winding in and out among the clefts of the rock, while through the less resistant soil accumulated in the hollows, the gathered torrents have ploughed deep and straight channels for themselves. The black soil is the *regur* or "cotton soil" *par excellence* of India, already referred to as the inexhaustible priceless treasure of the agriculturists of the Dakhan. It covers all the most level portions of the *desh*, and is merely the ultimate stage of the brown earth derived by direct disintegration from the ferruginous rock on which it rests. Mixed with decomposed vegetation, and in conditions favourable to the solution of the alkalis combined with silica in its felsspar, it forms a rich, light, and pulverulent staple, equal in fertility and ease of cultivation to the finely lixiviated alluvium of the Nile, and the *looes* or celebrated fluviatile loam of the Rhine-lands, and *tschernozieme* or wheat soil of Southern Russia; all these natural soils, like the *regur* of the Dakhan, being derived ultimately from crystalline rocks.

Such is the unvaried aspect of the Dakhan beyond the limits of the eastern spurs of the Sahydris; and the way in which the landscape becomes broken up as these spurs are gradually approached, is well exemplified by following the Poona hills backward from Sholapur to Khandala. Advancing westward from the former station, along the old military road, we meet, at Bhigvan, a flat, terraced, and symmetrical hill, protruding abruptly from the plain, the advanced link of a chain, looming like a coast line along the right horizon. It is the lowest step, the outmost ripple of the Sahyadris. At Patus the ramifications of their spurs become more lofty and complicated, closing in on the road, which, always rising and falling, is yet a steady, although still more easy ascent. At Arangaon, the fourth halt from Sholapur, a jasper-red wackè, is met with it, capped by a decomposing ferruginous trap. At the line of contact with the trap the wackè is hard and lateritious, but lower it becomes more and more earthy. Wherever the trappean rocks exist in the Dakhan we are sure to find this laterite near; it generally caps the *ghats*; and, according to Dr. H. J. Carter, the distinguished geologist of Western India, it is essentially "formed of red iron clay, the iron of which, by means of segregation, has formed itself into cells and irregular tubes, chiefly at the expense of the clay contained in their interior." It would appear to be derived from basalt, first disintegrating into a wackè, and then, by a sort of reaction, becoming laterite. It is soft when fresh dug, but dries into a hard stone on exposure, and is thus admirably adapted for building. Great masses of this strange rock occur in the Nizam's Dominions, eastward of Sholapur. Its special feature at Arangaon is its association with a powdery calcareous deposit, usually found elsewhere in nodules, called by the natives *kankar*, occurring irregularly throughout it in immense heaps. Thus a nullah or watercourse, to the west of the town, passes for some distance through nothing but *kankar*, and then through *kankar* and wackè, mixed promiscuously together. The *kankar* from being more concrete than the wackè generally stands out beyond it. Both are indifferently overlaid by a secondary effusion of trap, that appears, where touching it, to have crystallised the *kankar* into radiated zeolites. In a field from which the secondary trap had been denuded, the mounds of *kankar* amongst the wackè are indicated by smooth, white, irregular patches, many yards in diameter, scattered over the red ground. At Bhigvan, the puce and lavender trap rock [amygdaloid], which is friable at Sholapur, is hard, and used as a building stone. At Mulud, a section of the river bank, at a spot near the camping ground, presents at its base a brown trap, veined with zigzag bands of

* I believe that this local name for the Arabian Acacia is an indication of its having been introduced into Western India from Babylonia. In Hindustani *babuli* means "Babylonian"; *babil-khana*, "a brothel," literally, "Babylonian house"; *babiliyth*, "enchantment," and "wine," and also "poison"—with a poetical signification. It has ever been but a step:—"From mystic Ind to fleshly Babylon."

kankar, and above this a solidified stratum of *kankar*, crammed with worn blocks of various traps. It has resisted the action of the river so much better than the trap below that it projects for some distance in a ledge beyond the latter. It is covered by a deep deposit of black soil. In many parts of the river bed the trap is so completely decomposed that, although looking quite hard, it can be dug out with the hands to obtain water, or to form extemporary bathing-troughs; yet every crystal in the rock remains *in situ*. Below the pebbly bed of the Bhima at this place layers of soft, plastic *kankar* were being dug into, when I was there 30 [now 53] years ago, by the railway engineers. Patus is situated in a *regur* plain of immense extent, studded by several low, tabular hills, covered with huge black blocks of basalt, and contrasting strangely with the shoreless green ocean of *jawari* [Sorghum vulgare] fields from which they rise. Some of the blocks are boulders, others, from their quadrangular form, and the accurate way in which they are piled on each other, evidently remain in the situations wherein they were upheaved, and have been simply unmasked by weathering. The distant horizon is bounded by lofty mountains, mostly tabular, rising step on step, like an amphitheatre; a solitary group on the west is peaked; while between their rolling spurs, projecting like promontories into the plain, stretch broad reaches of luxuriant fields for miles, like inlets of the sea. From Yevut, until amidst the basaltic ramparts that on all sides dominate Poona, the scene is open to the right; while on the left the road lies along the base of an unbroken range of flat, stratified heights, on the most prominent of which stands a Hindu temple. Onwards, and always upwards, to Khandala, the formation attains its grandest developments, rising to the immeasurable, flat-topped mountain masses of alternate green forest bands and black basalt cliffs, and the fantastic peaks and pinnacles, already described; and exhibiting after the outburst of the rains in June the added feature of the gigantic, although transient, waterfalls, that from every declivity and precipice, and through every winding gorge, pour down from June to September the flood waters of the ubiquitous affluents of the Kistna.

And from these altitudes, so attractive in their serene silence from October to May, and so awe-compelling in the appalling atmospheric passion and uproar of "the South-West Monsoon" [Hindu *mausam*, Arabic *mausim*, "season"], we again look down, [now north, now south of Bombay harbour], upon the low-lying Konkans,—their densely wooded hills and dales, their palmy plains, their shore belt of grey salt marshes, or vivid green rice fields, fringed westwardly with dark green mangroves,—and beyond all the pale-green waters of the Erythrean Sea; the whole paradisiacal scene shining in the setting sun with the transcendent resplendence of various verds and shimmering gold.

(To be continued and completed in Part II.—THE PLOUGH.*)*

ELECTRIC TURRET CLOCKS—NEW "WAITING-TRAIN" TYPE.

By ALFRED E. BALL.

Several different systems of electrically-driven clocks have been designed and are in use in which the hands are sheltered from the wind; but it appears that no electrical system for driving the exposed hands of large turret clocks exists which is capable of dealing with all atmospheric conditions.

It must be understood that turret clocks with exposed hands are compelled to work under conditions unfavourable to good time-keeping. At times, during a gale of wind, for instance, or a snowstorm, the hands (and consequently the clock) are helped forward, and at other times they are retarded, so much so that time-keeping is interfered with, and in fact public clocks are often found to be stopped after a storm.

Horologists have for many years past applied themselves to the problem of separating, if possible, the time-keeping function of the clock from the hand-driving mechanism in order that ever varying pressure of the wind on the exposed hands may not affect the time-keeping of the clock. To this end, various *remontoir* trains have been invented and a number of gravity escapements. The best-known type of the latter is probably that of the late Lord Grimthorpe, which is largely and in fact almost exclusively used in this country.

An arrangement which was probably first adopted in England and is now favoured for large clocks in America, is to provide a light, finely-made time-train and impose on it time-keeping duties only, while a heavy powerful train is provided for driving the hands, the progress of the latter being controlled entirely by the former. Such an arrangement is certainly a step in the right direction. A mechanical connection, however, has to be maintained between the two trains of wheels, and consequently the two functions cannot be entirely dissociated.

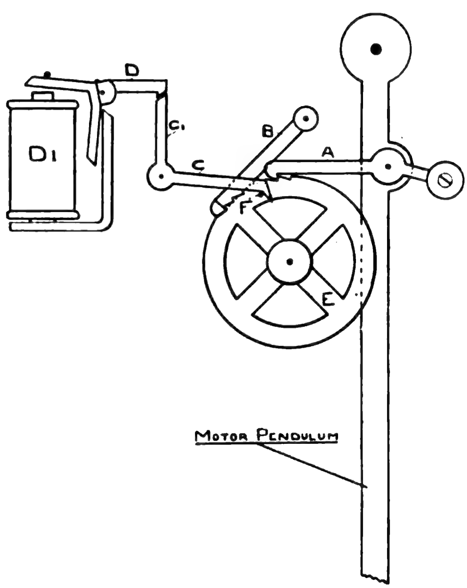
With an electrical turret system, however, which has been invented by the firm of Gent and Co., Ltd., whose factory is at Leicester, an entire dis-

sociation ot the time-keeping and hand-driving functions is obtained.

The electric hand-driving train, instead of being driven by a force of fixed value (such as a weight), as in a mechanical turret clock, which has to serve both when the load is heavy and light, is constructed so that its power becomes automatically adjusted to suit the load, the load in fact determining the power to be developed. The only connection between the hand-driving function and the time-keeping function in this new arrangement is the simple electric connecting wire, which obviously cannot transmit any mechanical resistance that may be applied to the hands.

This "waiting-train" movement consists essentially of a vibrating motor pendulum, and a half-minute time control. The vibrating motor pendulum, when working, becomes re-energised as often as the amplitude of its vibrations fall below a given value. In vibrating, the motor pendulum by means of a hook-shaped pawl, A (shown in the accompanying diagram No. 1), pulls around the 'scape wheel E, and the wheel-train gear, tooth by tooth.

FIG. 1.

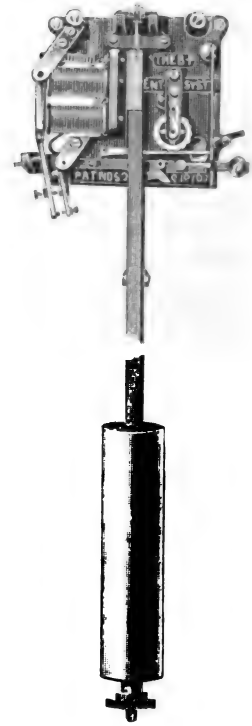


Normally the re-energisation of this motor pendulum takes place about once per minute. It is obvious, however, that if resistance is applied to the hands, such as is produced by wind pressure, storm, snow, &c., these re-energisations would take place more often, in fact, even as often as at each vibration, if necessary.

Working under these conditions, the motor-pendulum is found, as would be expected, to develop considerable power, even from 40 to 50 times that which is normally required. As all clocks with exposed hands have to deal with a varying load, the conditions of driving are completely met by the "waiting-train" movement.

The half-minute control operates as follows:— The simple train is so designed that the motor-pendulum in vibrating advances the hands half-a-minute in approximately 27 seconds. A pin, F, in the escape-wheel, E, then lifts the control-lever, C, and disconnects the pawl, A, of the motor-pendulum from the train of wheels by lifting it out of the wheel, E, and allowing the motor-pendulum to oscillate idly. It is here that the control from the entirely dissociated time-keeping mechanism comes into operation. This time-keeping mechanism (which is described

FIG. 2.



below) is known as the B.P. Patent Time Transmitter, and its duty is to send out electrical impulses precisely at each half-minute.

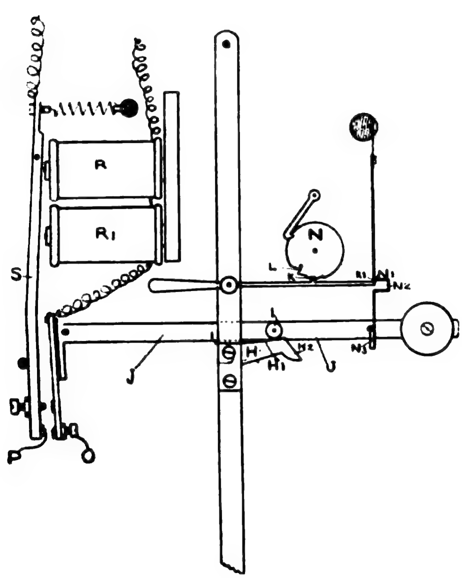
On the periodical half-minute impulse of the time-transmitter occurring, the control magnet, D1, becomes energised, the control lever, C, is released, and the motor-pendulum again drives forward the hands as before, the control being repeated at each and every half-minute, and in this manner the heavy exposed hands are propelled with practically a continuous motion. It is obvious that, no matter how exposed the turret clock driven by this system may be, its accuracy becomes equal to the accurate time transmitter controlling it.

The time transmitter mechanism effecting the half-minute control, and shown in illustration No. 2, is driven on a gravity principle which establishes

a new type of escapement or rather propellment, differing widely from gravity escapements hitherto employed. In the older types of gravity escapements, the pendulum is obliged to lift its own driving force at each swing in order to unlock the escapement. It has in fact to perform a recoil action. This work also is imposed on the pendulum at a time when it should be left severely alone, that is to say, at the end of each swing when its kinetic energy is at its lowest ebb, and when the pendulum is in a condition in which it would easily be influenced by varying friction while doing such work.

With the B.P. gravity principle the pendulum is entirely free at the end of each swing, and the work of unlocking the gravity lever and also the application of the impulse takes place when the kinetic energy

FIG. 3.



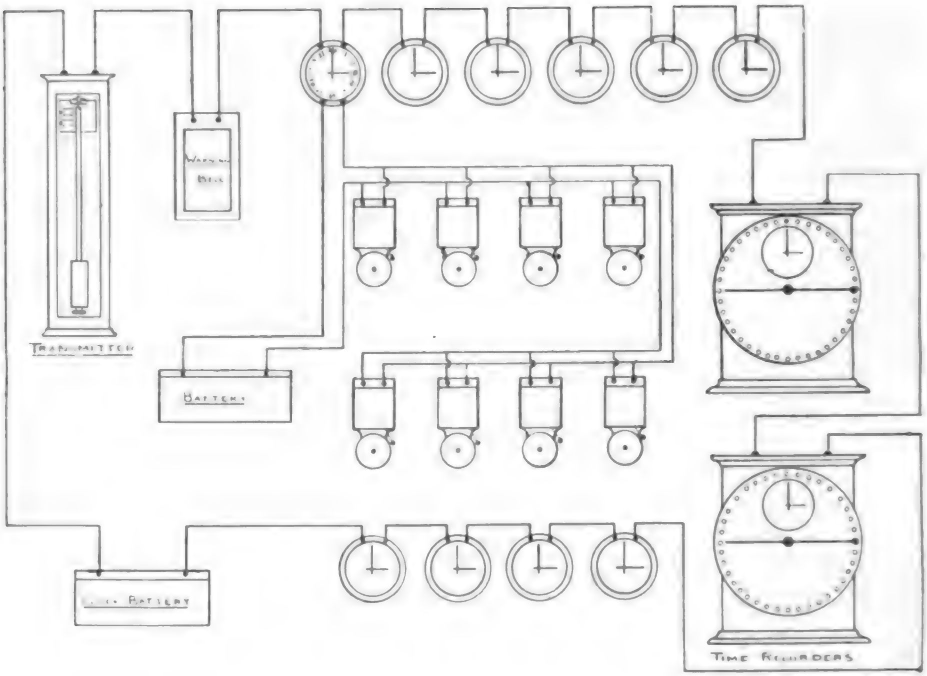
of the pendulum is considerable. The roller and pallet method of gravity impulse allows the gravity lever to be at all times very close to its work, and to be applied at the most advantageous moment.

The application of this gravity impulse to the pendulum is effected in the following manner:— Normally, when swinging with the pendulum, the pallet, H (shown in diagram No. 3), passes close under but does not touch the roller, I, of the gravity-lever, J. At each half-minute, however, the pawl, K, engages the deeper cut tooth, L, of the scape wheel, N, and enables the pawl extension, K_1 to engage the supporting catch, N_1, at the point, N_1 (instead of passing through the stirrup, N_2), and so releases the gravity lever, J, from the catch at the point N_3. The gravity lever being freed, the roller, I, drops on to the "dead" face, H_1, of the pallet, H, and on rolling down the incline, H_2, of the latter, imparts to the pendulum the impulse of constant force. This impulse is completed by the gravity lever being definitely arrested by the platinum surface, O, meeting the platinum surface P. The circuit being completed through their surfaces, the magnet, R, R_1, becomes instantly energised, and the gravity lever is lifted to its (original) potential position by the armature, S, the circuit being again broken by the contact-breaking screw, T. The current which flows for an instant through the magnet, R R_1, also flows through a circuit or circuits containing impulse clocks, turret clock controls, or other apparatus, such as workmen's check clocks, which it may be desired to operate by the periodical half-minute impulse. Diagram No. 4 shows such a circuit, in which are operated impulse clocks, workmen's check clocks, also a number of bells which are automatically rung (by means of contacts within one of the clocks) at the times of starting and stopping of work in factories, &c. The warning bell shown in the diagram is one of the features of the system. This bell gives audible warning when the battery is weakening—long before the battery would fail however—thus preventing a stoppage of the system through a failing battery.

The transmitter, when controlling a turret clock, is usually fixed at the base of the tower or similar low-level position where it can easily be reached for occasional regulation, and this does away with the need of mounting the steps of a tall tower. This low position also gives the advantage that the transmitter is not subject to the vibrations often present in a higher position in the tower. It will be readily recognised that to be able to fix the time-keeping mechanism in the most suitable position for good time-keeping, regardless of the position of the large clock, is an advantage which cannot be overlooked. It will also be recognised that with this electrical system of driving the hands, a large turret clock with exposed hands can be easily made to keep time to a degree of accuracy hitherto only associated with astronomical regulators. Electric striking and chiming can also be added which is entirely automatic in its action, and there is no limit to the size of the bells which may be struck. The whole of the apparatus is worked off Leclanché cells, the current consumption being small, and no winding or attention is required.

A description of this electric time-keeping system would hardly be complete without a short reference to an automatic lighting device, which turns on the gas or electric light (employed to illuminate large public dials) at dusk and turns it off at dawn. The time, however of lighting up may vary from 4.20 p.m. in the winter to 10 p.m. in the summer, with an equal variation of time for the switching off. Seeing that with electric clocks there is no longer need to ascend the towers for the purpose of winding, it would be a pity to have to do so each week just to reset the times of lighting up and

FIG. 4.



turning off. By an ingeniously-arranged cam, however — which by means of simple reducing gear revolves only once in two years — the times of lighting and extinguishing are altered automatically. The error due to leap years is so nearly allowed for, that the error remaining is only 10 minutes in 30 years, and at the end of this period can be corrected and reset for a subsequent period of 30 years in less than one minute. This device is the invention of I. H. Parsons and A. E. Ball, the patentees of the various clock apparatus described above.

CHINESE AGRICULTURE.

The last official census gives the population of the Chinese Empire as 430,000,000, covering an area of 4,278,352 square miles, and whilst the vast area is sufficiently great to accommodate comfortably the population, if properly distributed, many are driven, on account of climatic conditions and agricultural advantages, to certain districts, while the localities lacking in natural conditions that would ensure an existence, are practically deserted. China is an agricultural country, and more than two-thirds of its vast population are engaged in agricultural pursuits, but following a system that was in vogue centuries ago. Increased crops are not the result of advanced cultivation, or the application of modern devices to enrich the soil, favourable climatic conditions alone stimulating the yield. The implements of centuries ago are being constantly duplicated, and while, in some instances, a modern farm implement is brought into service, its reception is not cordially welcomed. While China's population is entirely dependent upon the earth's natural food productions for existence, the knowledge of agriculture seems to be limited to growing only a few things. This may be due to the lack of fertilising facilities, this branch of the farmer's work being such as to make it practically impossible for foreigners to use their products fertilised under the prevailing system. The American Consul at Nanking says that truck gardening, rice growing, and the cultivation of the silkworm form the practical work of the interior, but the land contiguous to the lakes and rivers is almost all unoccupied and uncultivated. The rice of the interior is the universal food, and varies in quality and production in accordance with the climatic conditions of the season. There is said to be no doubt that proper care given to wheat growing in China, as well as to other grains, would greatly enhance the product. The vacant lands drained by the great lakes and rivers, could, with proper cultivation, be converted into wheat-growing farms. The same could be done with the more elevated lands of the interior. It is said that there are about thirty-five flour mills in the empire, producing 1,500,000 barrels of flour, which, of course, come into direct competition with the foreign-made article, and which as time goes on will some day develop into satisfactory proportions. In the north-west of Kansu, which province is considered among the most fertile in China, wheat of fine quality is harvested. In Lower Yunnan the product is large

and satisfactory. In the provinces of Kweichow, Quantung, Fokien, Chekiang, and others, wheat of a fair quality is grown. While in certain parts of China grapes are grown and a sort of wine made from the juice, it is not of such a quantity or quality as to invite attention. The native spirit, which is highly intoxicating, is made of the juice of rice and millet, with the addition of some native ingredient. The textile plants are numerous in China, embracing hemp, China grass or ramie fibre, and cotton. Silk is the product of the worm fed on the mulberry tree; paper is made from the pulp of the bamboo, the fibres of which are used for cord or string. Oil is obtained from a native tree, and is called "wood oil." Oil is also made from cotton and rape seed, ground nuts, &c. The opium poppy, while decreasing under the influence of Imperial decrees limiting its cultivation, is yet a highly important element of soil production, and ranks in this respect with cotton, tea, sugar cane, and bamboo. The Chinese national beverage, tea, is of various qualities, the better and more delicate being the first crop on the sprout. It is harvested three times a year, and the leaves are prepared as black, green, brick, and dust tea. The brick tea is almost all exported to Russia and Mongolia; the other kinds are sent to the United States and Great Britain chiefly. The Chinese serve their tea in covered cups, the cover being of a saucer-shaped arrangement, which can be sufficiently tilted to admit of sipping, after which the cover is replaced. While the apparent blight of China is the absence of forests, unless it be in wild remote parts, there are some valuable trees. Among those producing a marketable substance may be mentioned the wood oil tree (t'ungtz shu), the gum-lac tree (ts'ihtz-shu), the tallow tree (kuentze-shu), the wax tree (pehlah-shu), the camphor tree (tsao-kioh-shu), the soap tree, &c. The mulberry tree, which contributes so much to the leading industry of China, is cultivated for its leaves, on which the silkworm is nourished. This latter industry is of great importance, and the manner of breeding and rearing the silkworm is one of the most interesting studies in China. These trees are plentiful in the provinces of Kiangsu, Chekiang, and Szechw'an. In other provinces another variety of the silkworm thrives on the wild-oak leaves, but the better quality subsist on the mulberry leaves. The greatest blessing in the matter of natural productions that exists in China is the bamboo. It is thought that over sixty varieties of bamboo exist, and it can properly be termed the national plant. It is applied to domestic, commercial, and industrial uses. Its shoots are a great delicacy, and are among the dainty and expensive dishes that usually grace the tables of the Chinese mandarins. Its roots are turned into canes, while the tapering spire is used in making masts, poles, tables, stools, chairs, chop sticks, pipes, umbrellas, fans, musical instruments, &c. The fruit trees of China are the peach, apricot, plum, apple, orange, banana, pineapple, mango, chestnut, persimmon, &c.

HOME INDUSTRIES.

Earnings and Hours in the Clothing Trades.—The report just issued by the Board of Trade as to the earnings and hours of labour of workpeople employed in the clothing trades in 1906 (Cd. 4844) contains much valuable evidence as to the exploitation of women's labour. Reference was made in these Notes last week to the Trade Boards Bill, about to become law, which empowers the Board of Trade to establish *minimum* rates of wages in the ready-made tailoring trades and others in which there is reason to believe that wages are exceptionally low, and the facts collected in the present report supply additional evidence of the sweating common in these trades, more especially among women workers. This evidence relates not to home workers but to operatives employed in factories and workshops who, poor as their wage often is, are paid a higher wage than the home worker. The men employed in the clothing trades do not seem to have much to complain of: indeed, as compared with the textile trades, the wages of the men appear to be 2s. a week higher on an average, the number earning less than 20s. a week being only 7·2 per cent. as compared with 18·4 per cent. in the textile trades. It is the women who are the sufferers. There is great uniformity in the average wages in the different trades, 11 out of the 16 trades dealt with showing an average of between 12s. and 14s. a week, but whilst there is great uniformity in the average wages of women as between trade and trade there is great diversity in the wages paid within the different trades. For example, in the dress, millinery, &c. (workshop) trades, 15 per cent. of the women earned over 20s. per week and 28 per cent. earned less than 10s. a week. The report gives a summary showing the earnings of women classified in four groups, those earning less than 10s. a week, those earning between 10s. and 15s. per week, those earning between 15s. and 20s. per week, and those earning 20s. per week or over. The majority in most of the trades earn between 10s. and 15s. per week, but 21·6 per cent. of all the women employed in the clothing trades earn less than 10s. per week, and that only when working full time. The highest percentage but one in this class is paid in the dress-millinery, &c. (workshop), where 28 per cent. of the workers earn less than 10s. per week, the average earnings for full time being 13s. 10d. per week. The highest percentage is in the corset (factory) class, where it is 28·8, and the average earnings for full time is the lowest of all, 12s. 2d. Fur stands best, the percentage of women workers getting under 10s. per week being only 9·4, whilst 27·2 per cent. earn 20s. and over, and the average earnings for full time amount to 16s. 7d. per week. The low wages indicated above are not to be taken as applying only to the clothing trades. In the textile trades, as was shown in these Notes recently, the wages paid in many branches are lower than in many branches of the clothing trades. Low wages, so far as women are concerned, are common to all, or nearly all,

trades, one of the reasons being that the women employed are usually partly supported by others. The report gives a Table showing the average annual earnings per head in 1906 of the workpeople employed in the clothing trades. Earnings vary from £29 in laundry workshops to £58 10s. in the fur trade, but the averages relate to the earnings of all the workpeople employed, and there are great fluctuations in the numbers employed owing to the seasonal character of many of the industries. A section of the report deals with the hours of labour, and shows that, including meal times and overtime, the hours for a full week vary from 50·8 in dress-millinery, &c. factories and bespoke tailoring to 56·8 in the silk and felt hat industy.

The Harvest.—The harvest of 1909 may be described as an abundant one much damaged by the weather. After a splendid fortnight the weather broke on August 17th and has been unsettled ever since. Much corn is still out, and much of it has been hurried into rick, so that a great deal of wheat is necessarily in poor condition. The barley crop is believed to be the heaviest grown during the last ten years, with the exception of 1906, but it has been much knocked about by the weather, with consequent damage to its quality, and it has been impossible to cut much of it by machines. The oat crop greatly improved in August, but there are striking differences in its condition. Taken as a whole it is somewhat better than last year, but not so good as the crop of 1907. Beans are the worst crop recorded since 1904, and have suffered much from black fly, and the pea crop is poor, having developed too much haulm. Potatoes are suffering severely from disease in some districts, and in all from the cold and moist character of the season. The root crops are exceptionally good, but the weather has been too cold for mangel-wurzel. The hop reports are more favourable than they were in August, but there is a sad collapse as compared with the position at the beginning of July.

The Whisky Trade.—One of the many industries affected by the Budget proposals is the whisky trade. The increase in the duty of 3s. 9d. per gallon has necessitated an increase in the price of proprietary blends of Scotch whisky by at least 6d. a bottle. This has created a new set of conditions in the distributing branch of the Scotch whisky trade, and, owing to the demand for whisky at the old price has intensified competition. This result has quickened the disposition of the three companies who are the principal distributors of blended whiskies in bottle to consider the possibility of amalgamation. There is a good deal to be said in favour of this course. Each of the three companies has created an immense and world-wide business largely by means of advertising, but the cost has been very great, and competition generally is growing in intensity. Amalgamation of the three companies should mean reduction of clerical and travelling staffs, raw material got upon easier terms, and considerable reduction of advertisement charges. All three companies' control distilleries whic supply a large portion of their needs, but they remain large buyers of single whiskies on the open market, and amalgamation should make them more independent of outside supplies. It is true that at present they can buy old Highland malt and other whiskies at prices little above the original cost, but this is due to the mad over-production of the distilleries in past years, and, as their production has been largely curtailed, stocks are being gradually reduced, and before very long should again be in proper proportion with consumption. Blenders will then have to pay more for their supplies, and it would be to their advantage to be less dependent upon outside sources.

Cutting Coal by Machinery.—In the United States, where the coal seams are favourable to the employment of machinery, machine cutting at the collieries has made great progress in recent years. In the American bituminous mines, as recently as 1891, the proportion of machine-mined coal was only about one ton in fifteen, say 6·66 per cent.; fourteen years later the proportion was 33 per cent., and every year sees the percentage grow. In the United Kingdom, the use of the machine cutter has been much less common, but here, too, it is now making headway. In 1902 there were only 483 machines at work in the whole country; in 1908 the number had risen to 1,659. In 1902 the machine-mined coal was something less than 4,000,000 tons, last year it reached 13,508,510 tons, and it may be taken that the Eight Hours Act will add largely to the use of the machine. At present it is used more commonly in East and West Scotland than in England, the percentage of machine-cut coal in East Scotland in 1908 being 14·2 per cent. In England, Yorkshire uses the machine more than any other district, the percentage being 8·1, but it is noteworthy that although last year there was a lessened total product of coal—261,528,795 tons, as against 267,830,962 in 1907—the machine-mined coal increased from 12,877,035 in 1907 to 13,508,510 tons. Outside Scotland, compressed air is preferred to electricity as the driving power. In 1908 more than 46 per cent. of the electrically-driven machines were in use in Scottish collieries, and statistics show that so far as England is concerned compressed air is more than holding its own, the belief being that it is a much safer power than electricity to use for coal-cutting in seams liable to fire-damp.

The Growth of Temperance.—The figures given by the Chancellor of the Exchequer in the House of Commons a few days ago show that the shrinkage in the use of wines and spirits continues. Taking the duty paid on wines in August of the three years 1907-9, the contraction is shown in the following figures which represent the duty paid during August of each of the years named—£74,000; £65,000; £62,000. It will be remembered that the

Budget of the present year makes no difference in the wine duties. Turning to the duty paid on spirits in the same month in the same three years the figures are £1,600,000; £1,477,000; £1,263,000. The heavy drop in August was largely due, no doubt, to the enhanced prices. The effect of the rise in prices is still more noticeable in the consumption of beer, which showed some increase in August, 1908, the duty paid in that month being £1,255,000 as against £1,228,000 in the same month of 1907, but in August, 1909, the amount fell to £1,128,000. The rise in the retail price must have had a good deal to do with the shrinkage.

EMPIRE NOTES.

Openings for British Capital.—These are many and important in every part of the British dominions. Take, for example, the opportunities offered by the extension of the Grand Trunk Pacific line to Prince Rupert, on the Pacific coast. During the present month, twenty-one town sites along the main line of this railway, West of Edmonton, Alberta, are to be put up for sale. According to the report of Mr. G. V. Ryley, Land Commissioner, it is scarcely twelve months since a series of town sites were placed upon the market, and already over 500 lots have been sold, all of them at very good figures, and the sales are rapidly increasing. These towns are located in a wealthy agricultural district, which is already peopled with settlers, and which, on the completion of the line, has in it the promise and prospect of great expansion. Many of these towns are admirably situated on lakes and rivers. Similar opportunities are afforded in Australia and New Zealand, where the extension of the railway systems of these countries is opening up vast areas of land, suitable for agricultural settlement. But these are only illustrations of the present opportunities offered by the Colonies for the profitable investment of capital.

Openings for British Settlers.—Whatever may be said about the difficulties surrounding the question of emigration, no one doubts that our oversea States, if they are to be developed and adequately defended, need a large and rapidly-increasing population—a population which should be drawn mainly from the British Isles. Canada fully realises this need, even while she is wisely exercising care as to the character and suitability of the immigrant she is receiving. In the adoption of this policy of selection, the Dominion Government is only acting on the lines of the United States authorities, who, by their drastic system of enquiry and examination, are seeking to stem, as best they can, the influx of "undesirables"—a system which, if it were employed by any one of our own oversea possessions would raise a storm of criticism and indignation. But, while exercising care in selecting the proper class of immigrant, Canada is doing her best to people her broad lands, and for this purpose she is welcoming not only people from this country, but large numbers of Americans, many of whom however, originally settled in the States from Canada. These are recognising the advantages the Dominion offers, and are taking up extensive areas in the prairie provinces. At the same time, by diligent propaganda on the part of the Dominion and Provincial Governments, the Canadian Pacific and other great railway lines, Canada is endeavouring to secure settlers from the British Isles. Australia, also, is beginning to recognise the absolute need of increased population, but the efforts she has put forth, thus far, are too limited and spasmodic to allow of any great success. It is true that some of the Australian States appear to be drawing largely from other States, according to the superior advantages for immediate settlement they are able to offer, but this, of course, does nothing to increase the population of the Commonwealth, as a whole. A new departure, however, is likely to be taken when the High Commissioner is appointed and the proposals for inter-State action, which have been tabled by Mr. Deakin, the Prime Minister of the Federal Parliament, have been considered and adopted.

Proposed Imperial Conference on Migration within the Empire.—Whatever separate arrangements the Colonies may make in regard to immigration, it is becoming increasingly necessary for all the authorities concerned, both home and colonial, to confer together on the whole question of migration within the Empire. Suggestions to this effect have frequently been made, but hitherto without avail. In view, however, of the recent Conference on Imperial Defence, in which the question of population is one of the most important factors, and of the necessity of dealing, at the same time, with our surplus population, and with the grave problem of unemployment, the time is opportune for further efforts to be made in this direction. Both in the interests of defence and trade, it is of the highest importance that Imperial action should be taken. Dr. Richard Arthur, of Sydney, the President of the Immigration League of Australasia, in a lecture delivered under the auspices of the Royal Colonial Institute, on "Imperial Emigration and its Problems," in May last, said:—"The subject of preference in trade is, undoubtedly, an important one, whatever view may be taken of it, but the best way to encourage trade between the Mother Country and the Colonies is to increase the population of the latter. Every person in Australia, New Zealand, and Canada, bought respectively, last year, goods to the value of £6, £8 10s., and £2 from the United Kingdom, in striking contrast to the United States, which took merchandise from the United Kingdom to the extent of about 5s. per head of population; Germany and France about 10s. per head, and the Argentine about £1." In the light of this fact, there can be no question as to the wisdom of encouraging the settlement of people, especially our own people, in our own oversea States, as, by so doing, we shall largely increase that Imperial trade which it should be our object to promote.

Manufacturers' Day in Victoria.—In order to encourage federal industries, Australian-made goods only were displayed in the shop windows of the cities and towns of Victoria on the 3rd inst., on what has been called "Manufacturers' Day." The movement appears to have been heartily taken up, and it is claimed, has given an impetus to the sale of locally manufactured articles. This step is an interesting indication of the desire and determination of Australia to produce for her own market, although, from an Imperial point of view, it has its unfavourable side, as imported British manufactures, as well as those from foreign countries, were excluded. Still, it is well for the British exporter to realise that Australia means, as far as possible, to develop her local manufactures. The character and strength of this determination are illustrated in the recent returns as to the number of factories in operation in Victoria in 1908 compared with 1904, and the relative increase of factory workers and value of output. The number of factories has increased 10 per cent., of *employés* more than 20 per cent., and the output has grown from 23 millions sterling to 30¾ millions.

Conservation of the Natural Resources of Canada.—A permanent Commission, consisting of thirty-two members, has been appointed for the purpose of securing a definite policy for the conservation and better utilisation of the forests, water power, minerals and other natural resources of the country. This appointment is the result of the International Conference held at Washington in February last on the general question of the Conservation of the Natural Resources of America. The members of the Canadian Commission will represent the Dominion Government, the government of each province, the universities, and the leading industries concerned.

NOTES ON BOOKS.

THE COLORIST. By J. Arthur H. Hatt. New York: D. Van Nostrand Company. 6s. 6d. net.

Mr. Hatt states on his title-page that his book is "designed to correct the commonly held theory that red, yellow, and blue are the primary colours," and in his preface he refers as the latest authority on the subject to "a French gentleman, M. E. Chevreul, a manufacturer of dyestuffs," who "made an extensive series of experiments with colors." The value of the work of this most distinguished chemist is of course fully recognised; but it is also perfectly well known that its present value is lessened by the fact of its being based on Brewster's old theory that the three primary colour sensations were red, yellow, and blue. Of course the Young-Helmholtz theory has long since superseded that of Brewster, and is familiar to all students of the subject, however elementary their knowledge. But the writer of this work does not seem to appreciate that while the theory that there are three primary colour sensations appreciable by human sight is accepted, there can be no possible justification for speaking of any colours as being primary in a scientific sense. On the other hand it is a perfectly convenient nomenclature either to call red, green, and violet primary colours, since by suitable mixtures of these three hues, any other tint can be produced capable of appreciation by the human eye; or else to call red, blue, and yellow primaries, since by suitable mixtures of pigments of these colours, the artist, or the colour printer, can in the same way produce all the tints that he requires.

The author also is quite mistaken in supposing that there is any want of a good text-book on colour based on the most recent scientific principles. It would be easy to mention several.

A useful suggestion is made by the writer that a whirling-table, and a set of suitable coloured discs, might be used for practical purposes for the reproduction and matching of any required colours. But the first difficulty is that practical people are not prepared to agree upon a standard series of colours; while there are a good many minor difficulties arising from the differences of the texture of materials. The suggestion was indeed made some years ago by Sir William Abney, who also pointed out that if a standard series of tints could be agreed upon, it would be possible to reproduce them by the mixture of certain selected rays from the spectrum, and these tints could be conveniently reproduced at any time, when the numbers indicating these rays were given. For commercial purposes, however, the difficulty of differences in texture would still exist, and the standard series of colours is yet, and is likely to remain, unsettled.

DRAWINGS FOR MEDIUM-SIZED REPETITION WORK. By R. D. Spinney, A.M.I.Mech.E. London: E. and F. M. Spon, Ltd. 3s. 6d. net.

The notes of which this little volume is composed, are chiefly intended for engineers who wish to supervise the preparation of drawings made for the guidance of men engaged in repetition work, *i.e.*, the making of similar parts of machines in considerable quantities. In order to simplify his task, the author has thought it advisable to restrict his example to parts of motor-cars, but the student who has learnt how to deal with these should have no difficulty in applying his knowledge to problems in kindred branches of engineering. The word, "drawings," is taken by Mr. Spinney to cover "the visible result of the draughtsmen's labours, and includes the fullest instructions for the buying and making of the component parts of the machines:" thus, we have sections on such subjects as—rules for a drawing office staff, standardisation by means of lists, standardisation of clearances, methods of indicating tolerances on drawings, division of costs between material, labour and special tools, &c. The book is full of very practical information, and gives a comprehensive but succinct account of the work of the drawing office.

INDIAN SECTION.

THE MAHRATTA PLOUGH.

By Sir George Birdwood.

PART II.

The Plough.

Doth the plowman plow all day to sow? * * * Doth he open and break the clods of his ground? When he hath made plain the face thereof * * * doth he not put in the wheat in rows, and the barley in its appointed place, and the spelt in the border thereof? For his God doth instruct him aright and doth teach him, Is the bread corn ground? * * * This also cometh forth from the Lord of Hosts, which is wonderful in counsel and excellent in working.—Isaiah xxviii., 24-29.

When engaged in the contemplation of the creative power of the Almighty as manifested in the geography and general physiography of the Mahratta Country, we are apt momentarily to regard merely human affairs and interests as altogether insignificant and contemptible; and to exclaim with the Hebrew Psalmist:—"What is man that Thou art mindful of him? and the son of man that Thou visitest him." And yet when we come to examine the wonderful ways in which the Mahratta *rayat*, or cultivator, has adapted himself to his surrounding conditions of soil and climate, and gradually secured his economic mastery over them, it seems to us again as though the Almighty had contrived them to no other end than to subserve the purposes of man; and as if indeed the Godhead's Self was one with Nature, or the Divine Reason residing in the whole world, and in its parts, and adjusting and determining them all to the abiding well-being and highest happiness of humanity.

Between the reaping in January and February of the *rabi* [literally "spring," otherwise called "the cold weather" and "the dry weather"] crop, consisting chiefly of wheat, barley, grain, peas, lentils, and safflower, sown in October and November, and the sowing in June and July of the *kharif* [literally "autumnal," otherwise called "the summer"

and "the rain"] crop, consisting of *jawari* [Sorghum vulgare], *bajri* [Penicillaria spicata], rice, maize, and numerous species of country pulse, and *til* [Sesamum orientale], all reaped in October and November,—in this fallow interval between February and June, the central plain of the Dakhan assumes, particularly during the sullen stillness of the direct and the reflected solar heat from 11 a.m. to 3 p.m., a scorched and desolated appearance; a yearly recurring memento of the ominous fact that Southern India after all lies within the solstitial, and therefore desert zone of the northern hemisphere; and that only by a wide promotion by the State of scientific forestry, and of irrigation works, such as dams along the natural lines of the trap dykes crossing the rivers, and by assiduous cultivation on the part of the *rayat*, can even the Mahratta Country, beyond the immediate shadows of the Sahyydris, be made certain of an adequate rainfall and water supply, and secured against famine. But all is changed, as by some supernatural spell, with the first fearful deafening appeals of the burst of the Monsoon, and the furious downpour, amid sudden gleams and flashes of lightning, and ceaseless reverberations of thunder, of the divinely odorous* and revivifying rain. In a single night, as I have known it happen at Kaladghi and Sholapur, the parched earth of the four previous months turns to the tenderest, liveliest green; rivalling in softness of texture, and outvieing in vivacity of hue, the azure of the now refreshened skies outstretched above. And when the blossoms of this, the true Indian spring, begin to appear upon the green expanse, and, trembling like stars in every breath of air that stirs across them, first unlock their painted petals, white, and red, and blue, and yellow, and purple, to the expectant day, beholding them, one feels that there is no pleasure under heaven equal to that of looking upon bright, fragrant flowers, fresh blooming in their native fields; and wonderful as is the revelation of the forest vegetation of the Sahyadris, the charm is still greater of the enchanting inflorescence of the vernal Dakhan plains.

A few weeks later, and round all the hamlets and villages, or rural townships, and the palatine and sacred cities [Civitates Neocoræ] of Maha-rashtra, as far as the eye can reach, the fields are already everywhere swelling high with pulse and cereal grains, oil seed, and fibre and dye-yielding plants, sown for the autumnal harvest.

Pliny tells a story of a Roman freedman, who having found himself able from a very small piece of land to raise a more abundant harvest than his neighbours could do from the largest farms, was accused of enticing away their crops by sorcery; when, pointing to his firmly-hafted mattock, and stoutly-bound plough, and sleek oxen, all of which he had collected in his defence before the magistrate: "Here, Roman citizens," he cried, "are my implements of divination; but it is impossible for me to exhibit to your view, or to bring into this Forum, those midnight toils of mine, those early watchings, those sweats, and those fatigues." It is the perfected indigenous plough of the country, the product of three thousand years experience, and the master's eye everywhere, that not once, but twice in each year, brings about the same magical results in Maha-rashtra, and, I might add, throughout India.

Some nine or ten [now 29-30] years ago Sir Philip Cunliffe-Owen had photographs taken of the native ploughs in the India Museum at South Kensington, for the purpose of enabling a leading firm of English agricultural mechanists to manufacture similar ploughs for use in this country.

They really need not have gone so far as India for improved ploughs for light soils, and small peasants' holdings, for the single stilt plough in use in the Shetlands is identical with the native plough used in the Dakhan. The foot-plough, *casehroom*, of the Hebrides, is yet simpler; and it is probably the simplest plough now known; and comparable in Europe only with the αὐτόγυον* of the Greeks. It can be carried on a man's shoulder, or under his arm, when he goes forth to his work in the morning, and returns therefrom in the evening; and it would be really more useful than any Indian plough in the cultivation of the small patches of arable bog-land in Ireland.

I believe it was also the hope of the English firm to undersell the native manufacturers of agricultural implements in India. It was an evil hope, but, fortunately, also a vain hope, for there is no chance of its ever being fulfilled. In India the cultivators manufacture their implements almost entirely themselves. In the Mahratta Country the *rayat* makes up the whole of the plough himself, except the iron work on it. This is prepared separately, and

* "Et cum a siccitate continua [terra] immaduit imbre; tunc emittit illum suum halitum divinum, ex Sole conceptum, cui comparari suavitas nulla possit."—Pliny, xvii. 3 (5).

* Compare Virgil, "Georgics," I, 170:—"et curvi formam accipit ulmus aratri."

so adjusted to the wood work that, after the days' ploughing is done, the *rayat* removes it, and carries it home with him every night. This iron work is all for which he pays directly "out of pocket;" and the price of the whole plough, wood work and iron work, is from 2½ to 3 rupees, *i.e.*, 5s. to 6s.* The cost of the native drill plough is from 5s. 6d. to 6s. 6d., including the wooden receptacle [carved with figures of the merry-hearted rural gods, Hanumant or Krishna], into which the seed in sowing is poured. No English manufacturers, here or in India, will ever make ploughs below these prices. In the Mahratta Country, a slighter plough is also used for the light ferruginous soils of the *mavals*, and a heavier for the deep-stapled black soil of the *desh*; but everywhere these two ploughs are made convertible by means of a weight, that can be fastened to or removed from the ham of the plough. There are also two kinds of drill ploughs, one used for sowing safflower and gram, and the other for sowing *bajri* (Penicillaria spicata), and *urud* (Phaseolus radiatus). The Indian bullock hoe is most effective for cutting up the stalks and roots of plants and loosening the earth wherein they have grown. It invariably follows the drill plough to cover in the furrows sown by the latter.

The application made by these English manufacturers to Sir Philip Cunliffe-Owen is, however, most interesting and instructive, as showing that even in agriculture England has lessons to learn from the natives of India. I had great practical experience in flower, fruit, and field cultivation all the time I was in Bombay, and always took the most intimate interest in the ways and means of native agriculture; and I am convinced that all the doctrinaire outcry against it, from the days of Tennant and James Mill downwards, as unscientific and wasteful, is as ignorant and insular as is the stereotyped depreciation of the industrial arts of India, by the same writers, and in the reports on the earlier International Exhibition held in Europe.

This is not the occasion for entering into any lengthened chemical statement on the subject, yet I would wish briefly to set forth here some of the more striking facts in proof of the exhaustless richness of the Indian soils, and the perfected science of Indian agriculture. There is no manure known more fertilising than March dust. Its fruitfulness is proverbial. *In India we have this March dust blowing everywhere all through the year.* In the Dakhan the deep-stapled black cotton soil is ploughed through and through to the bed rock below it by the wide gaping cracks formed in it during the hot season, from February to June. So soon as these cracks are formed they are filled with the fine blown dust which loads the winds that all day long, and all through the night, sweep the whole country. And as soon as the cracks are filled, new ones form again at once; and thus the soil is kept in a perpetual state of almost molecular disintegration and movement, and is ceaselessly reoxygenated by these simple, natural processes, to its lowest depths.

The trap rocks forming the substratum of the Mahratta country abound in quartzose and zeolitic crystals, containing all the mineral constituents necessary for the renewal of arable soils. I have seen millions of tons of these crystals heaped up on the weather-worn eastern slopes of the *ghats* about Yevut and Patus. There they lie, baking and cracking in the sun, and eroding in the wind, during all the hot season; and when the overwhelming rains follow they are rolled for hundreds and hundreds of miles along the beds of all the rivers that pour down from the *ghats* across the Dakhan to the Coromandel Coast; and with their flood waters spread the finely lixiviated fertilising dust into which the crystals are ceaselessly ground and comminuted far and wide over all the plains of the Dakhan. The black "Cotton soil" of India, needs, in short, for ordinary field cultivation, no other manuring than that which in this way it receives from the open hand of Nature. Yet there is always in every village plenty of the best material for artificial manuring, where it is needed, in the deposits formed in the village tanks. It is in constant use for garden cultivation. *But in truth the whole soil of the Dakhan is in a sense tank deposit.* The trap formation of Western India slopes, as has been shown, from west to east, like a shelving beach, and crops above the general surface of the Dakhan in a succession of reefs, running at right angles to the eastern spurs of the Sahyadris, between the Malabar and Coromandel coasts; and the staple of the soil of the Dakhan was originally deposited from the succession of fresh-water lakes, formed by the rain water falling on the Sahyadris between their eastern spurs, and pounded back by these longitudinal trap dykes; lakes which at one time covered the greater part of the surface of Southern India. When the rocky barriers were at last forced,

* At the rate of exchange during my time in Bombay.

the waters of the lakes drained off into the Bay of Bengal, through the channels now marked by the courses of the Godavari and the Kistna; leaving the plain of the Dakhan covered to the depth of often thirty and forty feet, with its exhaustless arable soil. One can always trace where these rents have taken place by the great breadth of arable land behind them, and the sudden contraction of the bed of the river, which often at these points flows with a peculiar noise as between closing flood-gates. The village of Gulgula, near one of these rents in the course of the Kistna, just beyond Mudhol, derives its name from this noise. It is the same word as "gurgle" and "gargoyle," and as Gilgal, the name of two or three places in Palestine, and of Silsilis [the soft Greek form of the Arabic Jiljilleh], the name of an ancient town on the Nile, near a rocky barrier in the course of the river that was burst by the lake once existing behind it within historical times.

I am referring, of course, to the historical black soil of the Dakhan, not to the red; the specific "Cotton soil" of Anglo-Indians, and the *regur* of the Hindus. In this word the syllable "*ur*," *i.e.*, "*ar*," is probably the same root, referring originally to ploughing, that in so many Indo-European languages enters into words connected with agriculture, and the ideas and institutions derived from agriculture, such as "arvum," "aratum,"* &c., &c., harvest, altar, area, arable, aristocracy, &c. It is the root of the word Arya. *Reg*, *i.e.*, *rig*, is the same word as the Scotch "riggs" (entering also into *Rig*—[Veda], "regular," &c.), or the lines of heaped up earth formed in ploughing. *Regur*, therefore, radically means simply "arable," and this ancient Hindu designation of the "Cotton soil" of the Dakhan is an incidental proof of its immemorial reputation for fertility.†

There is also another unmistakable proof of its inherent fertility. Pliny, in enumerating the different qualities of arable soil, pretty much in the same way as we find them enumerated in the Settlement Reports of the Bombay Presidency, and describing the tests for them, points out that the one infallible characteristic of a naturally rich and wholesome soil is "the divine odour" it exhales [v. Footnote, *supra*], when it is first turned up, or when the first dews of twilight fall on it, or rain after prolonged drought. Every one who knows India will recognise that this is the distinguishing odour of the black "Cotton soil" of the Dakhan; and the authentic credential of its being the charmed treasure that assures the fortune, the felicity, and the fame of India.

The Hindus habitually use manure in the cultivation of rice. Some time in the hot season the land is strewed with all the refuse of the homestead,—and floor sweepings, and old thatch, old clothes, *et cetera*, all are burned together on the surface of the rice fields. Then when the rains set in, the ashes from this burning are trodden by the men, women, and children, and by the cows and buffaloes, into the ground, until the whole surface is kneaded into a plastic, cohesive mud, called *chikal*, in which the rice is sown. The effect of burning the manure on the surface to be sown is to bake the ground immediately below the upper layer of fertile mud into an impervious bottom, which prevents the rain from draining through; rice requiring that its roots should be completely covered with water all the time it is growing. In a carefully cultivated rice field, or rather pond, the water of the rainy season, June to September, disappears only by evaporation; and by the completion of this process the grain is ripe for the harvest. More than this; rice cultivation, and brick and pottery making, are almost everywhere interdependent industries in India. The natural crude clay of the soil is too contractile, and too little cohesive for brick and pottery making. It has therefore to be kneaded with ashes before it can be used for these purposes; and in fact it is the *barsat-mati*, or "rain-earth" of the rice fields, always used for the best native bricks, and pots and pans throughout the Mahratta country. The potter is almost always also the rice cultivator of the village. *There could not be a stronger proof than this of the thoroughly practical and scientific character of Indian agriculture*. The simple reason why every attempt by self-sufficient Englishmen to make bricks and pottery in Bombay at first proved a ruinous failure was that crude clay, obtained, as in England, from the first ground to be purchased in the market, was used in their manufacture, instead of *barsat-mati*.

In the Dakhan the fields are never ploughed

* The English name of the plough, the immediate derivation of which is uncertain [v; Skeat—sub plough and plover] refers to the boat, and bird-like shape and movement of the implement itself: going back to a Sanskrit root signifying float, swim, fly, wash, boat, &c.; from which, through the Germanic language, we get the words fly, flock, fowl, float, fleet, &c., and hypothetically plover; through the Latin languages lustre [of 5 years], lotion, lavender, pluvial, &c.; and through Greek [peri-]plus.

† The word *regur* is Telegu and Kanarese, and, as actually used throughout Southern India, means "black-[soil]."

oftener than once in two years, and in some places only once in four or five, and even six years. The surface *regur* does indeed become exhausted by continual cropping without ploughing; but with occasional ploughing, just to turn the soil, and, still more important, to clear away the thick mat of creeping weeds, its fertility is exhaustless, if it is of any staple, and a foot is sufficient. *In a word, regur is itself manure in its final chemical form; and the Sahyadri mountains and their spurs, its original source, may be compared to an everlasting mound of manure, and the Monsoon drainage of them to liquid dressing, by the regular application of which the incorruptible vitality of the regur deposits in the plains below is perennially renovated.*

The *nangar* [cf. "anchora"], or ordinary Mahratta plough, is made up of the six following parts* :—

1. The *dant*,† "dentale" or "dentalia," of the Romans, ἔλυμα of the Greeks, the body of the plough, or share beam of *babul* wood [*Acacia arabica*].

2. The *phal*, "vomis" of the Romans, ὕννις of the Greeks, *sikka* of the Hebrews, the spade-shaped iron share, fastened to the share beam by its long handle [*pahla*], and a triangular iron girdle called *wasu*. It will be remembered that the Roman spade was called "pala."

3. The *ruman*, "buris" of the Romans, γύης of the Greeks, *dakas* of the Hebrews, the upright stilt, or plough tail, fastened into the broad end of the plough beam.

4. The *mutiah*, "stiva" and "manicula" of the Romans, ἐχέτλη of the Greeks, *kabusa* of the Arabs, the cross handle passed through the top of the *ruman*, by which the plough is held and guided.

5. The *alus*, "temo" of the Romans, and ῥυμός [cf. *ruman* above] of the Greeks, *buruk* of the Arabs, the pole or plough tree, by which the plough is drawn.

6. The *juh*, "jugum" of the Romans, ζυγόν of the Greeks, the yoke for the oxen drawing the plough.

This plough can easily be converted from a light to a heavy one by placing a stone weight on the share beam, or by having a second heavier share beam to substitute for the lighter when necessary. A light plough, drawn by two oxen, is used on the acclivities of the *mavals*, but in the *desh* a heavy plough, drawn by four or six, and even eight, oxen is occasionally used.

The drill plough, for sowing at the same time as ploughing, is also of two kinds—the heavier, called the *moghar*, for sowing gram and wheat; and the lighter, called *pabhar*, for sowing millets and other small grains. Both are composed of the eight corresponding parts following :—

1. The *lohr* or roughly triangular transverse beam, which is heavier in the *moghar* than in the *pabhar*.

2. The four *phan* [cf. fangs], or pieces of wood inserted, pointing forwards, at regular intervals at the lower edge of the transverse *lohr*.

3. The four *pharoli*, or four iron tips of the four *phan*.

4. The four *nala* [nullahs], or hollow bamboos inserted by their lower ends through the four *phan*, and opening out on the ground, behind the four *pharoli*.

5. The *charh*, or wooden cup [carved with the images of Hanuman, Krishna-Veshnu, or Siva, or all of them] into the bottom of which the four converging *nala* are inserted by their upper ends; and thus carry off the seed poured into the *charh*, and deposit it through each of the four *phan* in furrows, simultaneously turned up by the four iron-tipped *phan*.

6 and 7. The *dandi* or plough-pole; and the *juh* or yoke.

8. The *ruman* or plough tail.

The whole of the apparatus for sowing, the *char* and four *nala*, is removable, and this plough can therefore, when required, serve as a harrow.

It is identical in principle with the drill plough of Mesopotamia* represented on the black stone monument of the Assyrian King Esarhaddon, B.C. 681—668, now in the possession of the Earl of Aberdeen; and looking at this figure, and considering that lower Mesopotamia was the earliest seat of advanced agriculture, including river damming and canal construction, in Anterior Asia, there can be little doubt of the drill plough of India having originally been obtained from Babylonia. It was probably introduced into Western India by sea, direct from the Persian Gulf; while the ordinary single-stilted plough would seem to have passed from Mesopotamia overland into North-Western India, through Persia.

* Read with this,—Hesiod, "Works and Days," 426 *et seqq.*; and Virgil, "Georgics," I, 161-75.

† The Roman *dentale* was sometimes made up, as in the Mahratta *danti*, of two symmetrical pieces, and its name then took the plural form of *dentalia*.

* It is figured in Canon Rawlinson's *Ancient Monarchies*, ii. 198. Edition of 1864.

The Greeks and Romans must also through their common ancestors have received their single-stilted plough from Mesopotamia; while the later double-handled plough of Europe is to be traced back to the influence of ancient Egypt.*

In the *kulav* or hoe, a long iron scraper, called *phas*, is attached to two lateral pegs called *janavli*, to the transverse beam or *lohr*, into which are inserted the draft pole, or *dandia*, supporting the yoke or *juh*, at its end, and the upright stilt or *ruman*, with its cross handle or *mutiah*.

The remaining draft implements are the *alvat* or *muhig*, a long transverse beam fixed to a pole and used to level down ploughed fields and break up clods; the *jang* or *janjia*, the common husbandry cart, consisting of a large wicker work basket-like body, set on solid hewn wooden wheels, and used for carrying weeds, rubbish, and manure; and the *gara*, consisting of a flat light frame, of four long longitudinal planks, fixed by three shorter transverse planks, set upon solid wooden wheels, and used for carrying produce—the "Tardaque Eleusinæ matris volventia plaustra," of Virgil, "Georgics" I., 163. The cost of the *gara* is Rs. 100, and it is the most expensive article of rolling stock in a Dakhan farmyard.

The chief hand implements are the *yila* or sickle, and the *koita* or bill-hook, and the *kudal*, *kudli* or pick; and so perfectly adapted are the forms of these implements to the work to be done with them, and so true the steel used in their fashioning, that in the work of the Victoria Garden, Bombay, I had to prefer them to the best American and English-made gardening tools. This is a complete list of the moveable plant required in the cultivation of the Dakhan soils.

The cut grain is stacked before threshing, and is threshed by being trodden out by oxen on some near spot, made smooth by damping it with water, and beating it down, and cow-dunging it, and allowing it to dry in the sun. A pole [*tevrah*] is then stuck in the middle of this open air floor, and six or eight bullocks, half on one side of the pole and half on the other, are driven round and round it, until all grain is tramped out; and the stalks crushed into a friable fodder much relished by the cattle. The winnowing or *upun* is done upon a winnowing basket [*upun-vati*], identical with the "mystica vannus Iacchi" of Virgil*; and the grain is then stored in baskets, called *kuning*, made of the twigs of the sacred *nirgand* [Vitex Negundo], and thatched over the top, like old-fashioned beehives, or in earthenware jars called *hotli*, of very archaic form and decoration, being square at the top and bottom, but bulged out between, and marked round the neck with bold notches, or a rope-like moulding. When the grain is wanted for household use, it is ground by the women in a hand-mill called *chaki* ["wheel"] consisting of two round stones, one turned on the other by a wooden peg fixed in the rim of the upper stone; through a hole in the centre of which the grain is poured in between it and the nether stone. Husked grains, such as rice, and some of the smaller millets, are pounded in a mortar called *ukal* with a pestle called *musal*. The latter is a straight piece of wood four or five feet long, tipped at the bottom with iron, and at the top with a round knob, cut on the stick itself. The mortar is of wood, shaped like a truncated hour glass, and notched archaically round the constricture of its body.

This exhausts the distinctive properties—the whole "arma Cerealia"—of a Dakhan *rayat's* farmyard; but in every considerable village there is sure to be found an oil mill, and a sugar-cane press; and among the surrounding fields and plantations one or more wells [*vihir*], with their high-raised, overhanging apparatus of running wheel, and folded large leather bucket, of about sixty gallons' capacity, for raising the water, and sending it flowing through a thousand tiny channels over all the adjacent acres of lush and swelling vegetation. They present one of the most characteristic sights round an Indian agricultural township; and nothing can be more delectable in the noontide of the cold season than to listen to the hardy, manful Dakhan *rayats*, stripped naked to their work, singing joyously at these wells, to the sweet, and enhearting musical accompaniment of the water ceaselessly outpouring from them into a widely murmuring maze of rippling rivulets and rills.

Add to these out-of-door properties the appliances to be found indoors, — the large earthenware or brass lamps, the jars for holding meal, spices, and condiments, the pestle and mortar for bruising them together, the kneading board and a rolling-pin for preparing the unleavened cakes of *bajri* and *jawari*, the

* Pliny, vii. 57 (56) writes: "We owe the use of oxen and the plough to Buzyges (*i.e.*, Ox-yoker) the Athenian; but others say to Triptolemus."

* "Georgics," I., 156.

iron girdle for baking, and the copper pots and pans in which the *bajri* and *jawari* porridge, the pulse porridge and pulse soup, and the spiced vegetable stews, and the sweetmeats, are cooked ; and you exhaust the whole inventory of the mechanism, from the plough downward to the necessaries of domestic furniture, of the agricultural life of the Dakhan ; of which the essential element, and the prime movers, so to say, in the development of the latent wealth of the soil into food and other products for human use, are the hardy, thrifty *rayat* and his wife, and his oxen, and his incomparable plough.

It is the simple agricultural life pourtrayed by Hesiod, Virgil and Pliny, and by the *Scriptores* [Varro, Columella, Taurus Æmilianus, and Cato] *Rei Rusticæ Veteres Latini*, and by Tusser; but without the restless, hustling spirit of emulous competition, that, from the first days of their enforced exodus from the East, has been the necessarily disturbing and disintegrating element in the agricultural, as in the general progressive civilisation, of the Aryas of the West. It is not meant that the steam-farming of England and America, if applied in India, would not augment the productiveness of its soil, or at least extend its area of production ; although for all the social disadvantages resulting from the growth of large estates in the West, the only advantage, in this very respect of extended arable land, England has over India is that, while a fraction less than one-third of the surface of land and water is under cultivation in India, in England one-half of the total acreage of the country is cultivated. But the point of my defence is that the Hindus, having never forgotten their natural interdependence among themselves, and having recognised their indissoluble fraternity as the first law of their social organisation, the responsibilities and obligations of which are enforced on all, from the highest to the lowest, it would be impossible to introduce prematurely the vaunted farming of England into India, even if its methods and appliances were in themselves improvements, without involving the destruction of the beneficent co-operative rural life whereon the whole system of the civilisation of the Hindus has been immemorially based. That system, and that life, like all else that is of human origin, are probably destined to disappear ; but, if we are wise, this will happen gradually, through self-evolved changes in the internal consciousness of the race of Brahmanical Hindus ; and as answerable, in the present, for the happiness of the people of India, as distinguished from the "progress and prosperity" of their country, or, in other words, its scientific exploitation, the last thing to be desired or encouraged by us in the hastening forward of the probably inevitable reconstruction of Hindu society by means for which the people of India are not yet prepared, and which could therefore only act with destructive and revolutionary effect.

The introduction of the machinery of Western agriculture into India is quite impossible in the present economic condition of the country ; and every attempt at it in my experience, has proved a flagrant and ridiculous failure. I remember a steam-plough being brought out to one of the Native States in the Bombay Presidency. It was led out festooned with roses and jasmine, like an Indian bridegroom, into a rich *regur* field, and all of us who were called together to witness the prodigies it was to perform, were also wreathed with roses, and touched on our hands and foreheads with *atar*, and sprinkled all over with rose water; and then with a snort, and a shriek, and a puff of smoky steam, the gigantic mechanism made a vigorous, loud-hissing rush forward, but, as was at once perceived, also gradually downward, until, after vainly struggling for awhile against an ignominious fate, it at last settled down silently and fairly foundered in the furrow it had so deeply delved into the soft, yielding soil. And then not all the king's soldiers, and all the king's men, nor all the servants of the incensed Bhavani [Athene Boarmia, the "Ox-yoker" here] the hereditary blacksmiths and carpenters from the neighbouring palatine village, could do anything with the portentous mechanism. Nothing could be done with it as a steam plough. It had been recklessly brought into a sacro-economic system wherein it had no place, except as another god, and another god it was at once made. As soon as it could be moved out of the field it was sided into the village temple hard by; and there its huge steel share was set up on end, and bedaubed red, and worshipped as a *lingam*, or symbol of Siva ; and there, I suppose, it stands an object of worship to this day.*

The Indian plough is, in short, part and parcel of a fixed crystallised life, wherein it is

* The late Mr. Grattan Geary, Editor of *The Bombay Gazette*, on reading this article in 1888, at once sent an agent to Jamkandi, who found the plough-share then still there in undisputed deity, as evidenced by its daily daubs of dominical red.

the primitive and primary integrant molecule, regulating the relations, and determining the dimensions, and the ultimate character of the entire and indissoluble economic, social, and religious system built up on it. In that life all are but co-ordinate parts of one undivided and indivisible whole, in which the provision and respect due to every individual are enforced under the highest religious sanctions, and every office and calling perpetuated from father to son by those cardinal obligations of caste on which the whole heirarchy of Hinduism hinges.

Thus the social aspects of a Dakhan village are as of a large family, all living together that united life of contentment in moderation, which is the perfection of human felicity. The first sound heard in one of these villages after the deep stillness of the night and just before the dawn, is of "the house father," who having, on rising, worshipped the family gods, is now moving about quietly, with his head and shoulders still wrapped in the *chadar* [" sheet "] in which he has been sleeping, quietly, arousing the bullocks and oxen, stalled either in a yard behind the house or in the porch in front.* It is a devoutly soothing sound, for it tells you at once that you are among a people setting about their daily duties *actually hand in hand with* GOD.

Then having got the cattle out into the road, and lit his cigarette of tobacco rolled in a leaf of the *apta* [Bauhinia tomentosa], and taken up his breakfast of *jawari* or *bajri* cakes, cooked the day before, and tied up in a cloth over-night, by his wife, with an onion, or some pickle, he strolls off at daybreak, keeping his oxen before him, to his fields; and there yoking the oxen, and stripping to his work, whether it be to plough, and to sow, or to reap,† he works on for a steady hour until eight o'clock; and again, after ten or twenty minutes spent in eating his breakfast, for four hard fagging hours more until mid-day.

Ere yet he leaves his home, the voice of his wife is heard singing as she grinds out from the hand-mill the supply of flour for the day; and this done, and the rooms all swept out and fresh cow-dunged, and the *tulsi* plant before the porch perambulated, and her own breakfast eaten, she cooks the dinner, consisting of fresh baked cakes of *bajri* or *jawari* meal, and either a mess of pulse porridge, or a pot of highly spiced pulse soup, she must be careful to carry to her husband by twelve o'clock. The cultivators within hail of each other generally take this meal together; and after the four hours from breakfast spent in the furrows, or amongst the stubble, they devour it with obvious zest of appetite, joking and laughing heartily all the time: so true is it of the peasant proprietor's independent life all the world over:—

*" Pingue solum lassat, sed juvat ipse labor."

Thus from half-an-hour to an hour is spent; and then up to two or half-past two o'clock, the men lie down to sleep, lying where they had eaten, on their *cumblis*, or out-of-door woollen wrappers. While they sleep, the women dine off the scraps that are left, and then either, at once return to their houses to attend to whatever may be wanted to be done there, and to prepare the supper, or spend an hour or two assisting their husbands in the fields previously to going home.

When the men awake they re-yoke the oxen, and resume their work for three hours more, or until the sun sets, at which signal they return in long winding lanes towards their respective villages, walking along leisurely, chatting and laughing, and always keeping their oxen before them. Then, tying up the cattle, and, after bathing, again worshipping the household gods, the husband at eight o'clock has his supper of pulse porridge.

After this the social life within the village —a life lived here, and now, and in every homeliest detail, with God and Immortality—suddenly bursts into its brightest, happiest activity. The temples of the gods are in turn all visited: those of Mahadeo, "the Great God," meaning Siva, and Bhairava, an incarnation of Siva, and of Hanuman, and any other of the lesser gods to whom there may be temples, or

* The ritualism to be observed in attending to cattle, and especially on the cow, is most minute, and would be exacting, but that it has become instinctive in the race of Brahmanical Hindus. You must not step over the rope to which a calf is tied; and must always approach and pass a cow on your right-hand; and keep your right-arm covered the whole time you are in the cow-shippen; you must never ride a cow, nor interrupt her while suckling her calf, nor be in any way annoysome to her. Shortly after the railway between Poona and Bombay was first opened, a cow having to be sent by a Hindu in the former city to another in the latter, its entrainment for the journey was telegraphed by the sender to the receiver in the equivalent of these terms:—" Her Holiness just booked by the — a.m. train to Byculla [a suburb of Bombay], please be at the station at — p.m. to receive Her Holiness."

† Compare "nudus ara, sere nudus" of Virgil's "Georgics," I. 299; and Hesiod's " Works and Days, 390."

* Compare:—" Robustus fossor rege est felicior." Also the culminating precept of Hesiod's "points of good husbandry."—" The hard working cultivator is beloved alike by mortal man and the immortal gods." " Works and Days," 309-10.

shrines, or altars, or but upraised, ruddled stones,—and these are everywhere.

Hanuman, or "Long-Jaw," is the favourite village god. Originally he was possibly the *totem* of the Vindhyan races of Central and Southern India; and he is adopted as their representative in the Ramayana. But in the officinal pantheon of the Brahmans he is a sort of satyr leader of the oreads and dryads of the wooded mountains and hills and dales of the Malabar coast and Gondwana: and as Arcadian Pan was the son of Hermes, so Hanuman is the son of Pavana, "the Vagrant," "Vagabond" wind, or a personification of Vayu,* who is "the Wind" also. He represents the sun as it seems, to those who pass through the forests of the Sahyadris, to leap from tree to ree above them. The gleams of light that shine suddenly on the wayfarer's path through dark woods, and the pleasurable earth-born glow that springs up in the youthful heart at the sight of the luxuriance of Nature, and again the feeling of awe that at times seizes the lonely traveller on suddenly coming on some uncanny spot, all these are Hanuman. Again, he is the shadows that steal at sunset through forests and across valleys, and from one hill-top to another. The vocal cloud of dust that swept from Eleusis towards the Grecian fleet at Salamis, like a wafted echo of the songs of the Mysteries, the Hindus would probably interpret as a higher apparition of Hanuman. He is, indeed, the topical personification of the vital power of Nature in its more familiar and more playful manifestations and emotions; and these the Hindus as naturally represent by a monkey, as the Semites of Anterior Asia represented them by the wild goat, the *atadu* of the Assyrian inscriptions, and *atud* of the Hebrews; names from which, through their Greek form, we derive the word satyr. Thus, in Western, Southern, and Central India, Hanuman is everywhere the favourite local divinity of the lower agricultural classes, whose innocent gaiety of heart, so promptly responsive to all the pleasanter conditions of their life, he precisely personifies: and in the Dakhan villages the vicinity of his temples is always of an evening a popular rendezvous.

Every month, moreover, and indeed almost every week, some religious anniversary is celebrated; the principal among the agricultural communities of the Dakhan being the following five: The Holi, or Saturnalia of the spring equinox, held towards the end of March. The Dasara, or "Tenth," held early in October, when, after nine days of mourning for the ravages of Mahesh-asura—"the Buffalo-headed demon," from whom the State and city of Mysore take their name—on the tenth day, in joy for his destruction, by Bhavani, all the villagers, the higher and lower "twelve" hereditary village officials, the Brahmans, the whole body of the cultivators, and even the occasional Mahommedan "sacrificer" or butcher within their gates, proceed in their gayest costumes to perambulate the village boundaries, and to worship the trees planted there, more especially the *apta* [Bauhinia tomentosa], and, where it grows, also the *palas* [Butea frondosa]. On this day also the Mahrattas of the great historic families celebrate the declaration of "The Great War in Bharata," the "epos" of the Mahabharata, between the Pandavas and their paternal cousins the Pauravas. Heralded by the arousing, archaic sounds of shawms, and bagpipes and kettle-drums—the last often mounted on a camel,—they sally forth from their palaces into the westward wild ["jungle"] in long, leisurely advancing cavalcades, their horses in full caparison of war, but festooned over their trappings with flowers; and themselves garlanded and crowned with flowers; and their spears, of many coloured fluttering pennons, all hung with flowers; and, as they move along, gathering from every *pulas* tree they pass its yellow blossoms, on turning, at the gloaming, homeward, they joyfully heap them on every woodland altar, or ruddled stone, by the way-side, calling them "gold" [*sona*],—as much as to say: "It would be gold—if we had it—we would heap on you with the like largess of heart." And wherever these gallant Mahratta princes ride that day, in their estatic vision, the good Lord Sivaji rides on before. The Devali, or "Feast of Lanterns" [literally "Lamprows"], held twenty days after the Dasara, and celebrated amid the greatest rejoicings in honour of Lakshmi, the wife of Vishnu, as the goddess of "Good Luck," and of Saravati, the consort of Brahma, and goddess of learning, and protectress of bank-books, ledgers, and all money accounts. These three solemnities are commemorated by all classes of the community.

The two remaining festivals are kept up

* Ariel is possibly, and aerial certainly, a form of Vayu; and both Vayu and [Pa]-vana are radically related; our English words wind, winnow, winter, &c., being more closely cognate with the former; and vague, vagrant, voyage, tan ["vannus," *éventaille*], way, wain, waggon, &c., with the latter.

exclusively by the women, namely, the Nag Panchami, on the 25th of July, in honour of the destruction of the serpent Kali by Krishna; and the Gauri, on the 25th of August, in honour of Parvati in her epithet of Gauri, "the Yellow-Haired." The latter is specially observed by making up sweetmeats in the shape of round balls and eating a couple of them before going to bed. For two months beforehand songs in honour of Gauri are nightly rehearsed by the women. Their principal employment, however, of an evening is in visiting from house to house, arranging the marriages in the village, and settling the names of the latest-born babies. Every Mahratta family has its crest, and no marriages can take place between families having the same crest—a clear survival of totemism.

The Mahratta women of the *rayat* class, although they soon lose the good looks of their girlhood, are a fine, healthy race, tall and straight grown, modest, frank, and chatty; and in their yellow, or shot red and purple, bodices [*choli*], and dark green, or indigo-blue, robes [*sari*], are everywhere, in the fields, or in the village streets, welcome objects to the artistic eye. The ladies of the higher castes, and particularly the *deshast* Brahmanis, are very comely, although not so fair as their *Konkanast* sisters. They are all known at a glance by their great beauty and richer clothing; and as one of them sweeps past [ἑλκεσίπεπλος] in her flowing *sari* of crimson, gold-bordered, nothing can be nobler than its glow against her olive flesh-tints, as it waves round her stately figure, and ripples in gold about her dainty feet, a study worthy of a Lombard master's canvas. And πυγοστόλος also is there, loitering in the shadows of the big temple, not illicit, degraded, and depraved, but a recognised institution, established, endowed, and, indeed, sacramental.

A great deal of conversation also goes on every evening with the village astrologer especially as to the right day and hour for sowing the different kinds of crops; and it is quite surprising to find the full and accurate knowledge the humblest husbandmen show, in these consultations, of the exact time the sun enters the successive signs of the zodiac, by which the sowing of rice, wheat, barley, *bajri*, *jawari*, and every other sort of grain, pulse, and oil seed, *et cetera*, is scrupulously regulated.* They prove themselves indeed as much at home around and about the zodiac, and among the burning stars, as in their own beloved fields, and with their conversable cows and calves and ploughing oxen; and the picturesque, Propertian* epigram:—

Nauta de stellis, de bobus arator.

is foiled of its antithesis in any reference to them.

All this intercourse conducted on the most familiar terms between the members of the same township. and in the open streets, by the light of the flaring oil lamps set, or hung, in every portico, and of the pillar of lamps, when occasionally lighted, before one or other of the temples, is of the most unaffected and cheering sociability:—

"—— that after, no repenting draws."

By ten o'clock nearly everybody has gone to bed; except that when the songs of Tukaram, or the stories from the Ramayana and Maha-bharata are sung on moonlight evenings, these joyous, blameless *al fresco* reunions may be kept up to nearly midnight. Then the deepest night again closes on each village, and its dependent hamlets, until six o'clock the next morning.

Thus in the division of the twenty-four hours the Dakhan *rayat* has, for the past 3,000 years, realised the vainly-hoped-for ideal of the English artisan, and at a twelfth of the cost:

"Eight hours to work,
Eight hours to play,
Eight hours to sleep,
And eight pennies [not shillings] a day."

He has realised also, and in its fullest security, the ideal co-operative life of the day-dreams of the socialists of the West. And is not this co-operative agricultural life of the people of India high farming in its noblest sense and conception of the term?

Pliny, writing on the "Maxims of Ancient Agriculture" (bk. xviii. ch. 8), asks: "In what way, then, can land be most profitably cultivated?" and answers: "Why, in the words of our agricultural oracles, 'by making good out of bad.'" Adding, "But here it is only right that we should say a word in justification of our forefathers, who, in their precepts on this subject, had nothing else in view but the benefit of mankind, for when they used the term 'bad' here, they only mean to say that which cost the smallest amount of money. The principal object with them was, in all cases, to cut down expenses to the lowest possible

* In *The Madras Mail*, 9th July, 1908, will be found a most informing and most interesting article, signed C. H. R., on the Ritualism in Agriculture as observed by the Hindus of Southern India.

* "Navita de ventis, de tauris narrat arator;
Enumerat miles vulnera, pastor oves."
—Propertius ii., 1, 43-4.

sum." And further on, he quotes, "that maxim of Cato, as profitable as it is humane: 'Always act [in farming] in such a way as to secure the love of your neighbours.'"

The enactments embodied in the Code of Manu, and cognate law books of the Hindus, have achieved this consummation for India, from before the foundations of Athens and Rome; and, through all that dark, backward, and abysm of time, we trace there the bright outlines of a self-contained, self-dependent, symmetrical, and perfectly harmonious industrial economy, deeply rooted in the popular conviction of its sacro-sanct character, and protected, through every political and commercial vicissitude, by the absolute power and marvellous wisdom and tact of the Brahmanical priesthood; an ideal social order, we should have held impossible of realisation, but that it still continues to exist, and to afford us, in the yet living results of its daily operation in India, a proof of the superiority, in so many unsuspected ways, of the hieratic civilisation of antiquity, over the secular, joyless, inane, and self-destructive, modern civilisation of the West: and of a truth, it is in the contemplation of the practical workings of this socialistic system of the Code of Manu that the sympathetic Englishman in India drinks deepest of the bliss of knowing others blest.

L'Envoi.

And this is the "unhappy India" of the writers on that country, who know not the things that really belong to its peace, and have acquired all their knowledge of it from "Statistical Abstracts" and "Blue Books."

Unhappy India, indeed! I might rather bemourn the unhappiness of England; where faith for nearly four centuries has had no fixed centre of authority; where political factions rage so furiously that men seem to have lost all sense of personal dignity and public shame, confusing right with wrong, and wrong with right, and excusing the vilest treasons against the Commonwealth on the plea of party necessity; where every national interest is sacrificed to the shibboleth of unrestricted international competition; and where, as a consequence, agriculture, the only sure foundation of society, languishes; and the peaceful plough, the mainspring of industrial activity, no longer holds its proper place of public honour and pre-eminence:—and no longer is heard throughout our land, from far across the fresh fluted furrows, the lulling lilts of the lowly ploughman, who, as he sturdily plods along:—

> "Sweetens his labour with some rural song."

The truth is, that closet publicists and politicians, trained in the competitive economic principles of the West, do not sufficiently distinguish between the prosperity of a country and the felicity of its inhabitants. Indeed, they do not discern the distinction. They dwell with their books, and not among the people; and that men do not live by bread alone is one of the strongest facts of life in India absolutely hidden from their eyes.

What we call prosperity exists only in figures, and has no place in the personal experience of the vast masses making up the population of the so-called "progressive" nations of the West. It merely means the accumulation of amazing wealth in the hands of a few, by the devouring, wolfish spoliation of the many; and in its last result, the bitter, stark, and cruel contrast presented between the West End of London and the East. And do Europe and America desire to reduce all Asia to an East End?

Happy India! where all men may still possess themselves in natural sufficiency and contentment, and freely find their highest joys in the spiritual beliefs, or, let it be, illusions, that have transformed their trade-union organisation into a veritable "Civitas Dei." *

* Mr. Malabari, the sanest and most sympathetic of native Indian [Parsi] "reformers," devoted the whole prime of his life to the advocacy of a rehabilitation of the Panchayat System [*i.e.*, Council of, nominally, 5, *panch*:—compare "punch" the Anglo-Indian "brose" or brew of 5 ingredients—spirit, limejuice, sugar, spice, and water;—and the Greek "punch," πενταπλόα,—the words *panch*, πέντε or πέντα, and five, being all one word, originally meaning "outspread"—like the hand with its 5 fingers] in Indian villages; but it has all been in vain—so far. It is a proverbial saying in India:—"In the Panchayat is God!" We speak of "the Wisdom of Parliament;" but that is sarcastic-wise, and with reference to the "Parliament of Dunces," the "Addled Parliament," the "Mad Parliament," &c. Nothing could be more fair, and reasonable, and beneficent, than our regulations for raising the land revenue in India, and it compares favourably with the rule of the Mahrattas and other Hindu princes, who levied from their Muslim subjects,—including the Nizam of Hyderabad, and the Emperor of Delhi, one-fourth of the assessed value of their crops,—the *chauthai*, or "chout" of which one reads so much in English works on India of late in the eighteenth and early in the nineteenth centuries. But even the *chauthai* was not so onerous as is often represented; for in closely parallel circumstances the Spartans took one-half of their crop values from the Helots, and the Athenian Eupatridæ one-sixth from the Attic Thetes. They all gained from the assessments being fixed—at least when there were no droughts!

* "Where everyone has his divinely co-ordinated place, and his security, and honour, and content therein; and no one is envious of another's higher estate, and reverence and happi-

Happy India, indeed! But how long before the Saturnian reign shall be brought to the same end in India as it was in Europe four centuries ago? The sight of our manufacturing and commercial wealth, the fruit of our competitive civilisation, so deceptively beautiful without, but within full of gall and ashes, like the apples of Sodom, has inflamed the people of India, in the neighbourhood of Calcutta and Bombay, with the same insatiable greed of gold as the opulence of Rome excited in the barbarians who were provoked by it—"the Nieblung's gold"—to the destruction of the Empire; and wherewith again the ancient and mediæval fables of "the Riches of the the East" inflamed the avarice, in the fifteenth and sixteenth centuries, of the renascent nations of the West, and lured them on, in speculative quest of India, to the huge invention of the Americas.

Through this contact between the East and the West at the Presidency towns, the traditionary ideal of life among the Parsis and Hindus is gradually becoming superseded by the English ideal; according to which the basis of all social advancement, and the standard of all moral worth, is the possession of money. That hangs on the hazard of a crude competition, in the prizes of which but few, of the many called, are chosen to participate; and thus in the place of the old world content with the conditions of existence, we are arousing in India a universal spirit of discontent, the characteristic incentive of modern civilisation, and have needlessly exaggerated it through the malign influences of the fastidiously secular system of eleemosynary education enforced by us on the country. The sinister shadow, as of the legendary Upas tree, on Western civilisation, is the slow poisoning wherever it becomes rooted, of the vital atmosphere of the spiritual life latent in our human nature; and there was no necessity for anticipating, by a direct attack on the ancestral faiths of the people of India, led as it is by professedly Christian missionaries,* the inevitable catastrophe that has everywhere dogged the steps of exclusively material civilisations, and at last involved them in self-destruction.

Examining in 1863 or 1864 some Parsi boys in the Fort School in Bombay, on my asking the meaning of the word "happiness," one of them instantly stretching out his arm toward me replied energetically, and with the applause of all his little class fellows:—"To make a crore of rupees [£1,000,000] in cotton speculations, and drive into (*sic*) a carriage and four,"† —adding, however, in the yet uncorrupted spirit of the boundless philanthropy of the ancient Buddhism of Asia—"and to give away lackhs upon lackhs in charity:"—and as well in princely public benefaction, as in inexhaustible private done and dole. Only a few weeks [now 21 years] ago a distinguished Bengali Brahman, to whom I was pointing out that he was not in the least obliged to break formally with the religion of his forefathers because he was an "Agnostic," replied:—"You do not understand. It is not simply your education that has made me an Agnostic; I have rather been forced to become one by the high standard of civilised life you have set up in India. I really cannot afford to be a Hindu, and spend so much as a good Hindu must on his 'undivided family,' and in general charity; not if I am to keep up appearances, on the same income as Christian and Muslim gentlemen, who have no such compulsory demands on their means."

Thus the lesson of the Indian plough, if rightly read, goes deep; and he who runs may read it‡; and the deepest gulf before England is that we are ourselves digging, by forcing the insular institutions of this country on the foreign soil of India,—India of the Hindus. That is the special lesson of the English steam-plough laid up, in divinity, in the Jamkhandi State.

POST SCRIPTUM. Sept. 19th, 1909.—I must add a postscript to thank Sir James Monteath for drawing attention to my negligence in not referring to the fruitful work done by the late Sir James Campbell in connection with the excavation of the Buddhistic relic mound at Sopara; and to thank him also for dealing

ness therein; where God is sought, and found, and magnified in everything; and where every one seeking and ensuing every other's good, realises for all the perennially inspiring human vision of a New Heaven and a New Earth."—St. Augustine, De C.D. xxii. 20, 30 *précis*-ed. Long may "God stay them in that felicity" in India. No wanhope—notwithstanding present appearances there! "Sinister omens" are, after all, sent from the right hand of the gods; and thanks to the wary wisdom, and deft dexterity of the Brahmans as "men of affairs," the concession of representative government, of the English type, to India, may yet serve to revivify and reinvigorate, and definitively restore their pristine powers, and salutary, because natural supremacy, throughout the country.

* The first and best triumphs of Christianity were won by absorbing and transmuting the classical paganism of Greece and Rome, and not by arrogantly defaming it. The true destiny of Christianity in India is not to reprehend and destroy, but to amend and regenerate Hinduism.

† "Quadrigis petimus bene vivere."—Horace, *Ep.* i. 11, 29.

‡ And verily, "he may run who readeth it."

so considerately with my default, when he might well have come down on it with the full weight and edge of an avenging "Lochaber axe." In a private letter Sir James Monteath states that there is no sheer drop of 2,500 feet at "Lodwick Point," Mahaleshwen, into the Southern Konkan. I saw the horse leap from the point, silhouetted against the sky as picturesquely, and impressively, as the camel on the monument to Gordon at Khartoum; and immediately afterwards looked down on it flattened out in the plain below; and the figure of the depth of the fall I erroneously give, is that, I presume, of the height of "Lodwick Point" above the general level of the Southern Konkan, and certainly not above the very spot on which it actually lay dead. Both these errors, the one of omission, and the other of commission, shall be corrected in any permanent reproduction of this paper, with others in praise of India, I may yet publish before I cease altogether to live to the purposes of my foster "motherland."

The only "toad-in-a-hole" of which I can speak with authority, is the lusty De'nshire "prog" of a chunk of beef baked in a large "cloam" dish with batter. GEO. B.

LONDON TRADE SCHOOLS.*

The problem of problems in London and elsewhere is to prevent children of fourteen years of age drifting into unskilled labour in which there is no element of permanence. The difficulty is increased by the decay and gradual disappearance of the apprenticeship system and the altered conditions of employment in workshops, which make them unsuitable places for the training of craftsmen.

An elaborate scheme of junior intermediate and senior scholarships established by the London County Council makes ample provision for the brilliant children of the London Elementary Schools. The really capable child, even of the poorest parents, may reach the highest position by means of the scholarship ladder, passing at the age of eleven years into the secondary school, and thence by means of scholarships at the age of nineteen to the University or higher technical school. Provision is also made for the transference of children who do not reach scholarship standard to pass on to a higher form of elementary school in which a special bias may be given in training for commercial or industrial life in a course of instruction extending for a year or two beyond the age of compulsory attendance.

The Trade School, however, is of a very special type for children who have to enter upon their life's work at the age of sixteen or seventeen, and who have already decided upon the trade they wish to enter. The age of entry into the trade school coincides approximately with that at which the boy or girl normally leaves the elementary school, viz., thirteen or fourteen years of age, and the course of instruction lasts for two or three years.

In London the boy or girl of fourteen who is physically strong and has received a fairly good education, has no difficulty whatever in obtaining employment at a rate of remuneration which appears liberal for a child of this age. The consequence is that in the elementary school the vast majority of the children leave immediately they reach the age of fourteen and become wage-earners. In order to keep children at school above the compulsory age for any definite period it is absolutely necessary, not only to give them free education, but, in addition, maintenance scholarships which will recoup the parents to a certain extent for the loss of the earnings of the children.

The scholarships for trade schools for boys extending over a period of three years are generally of the value of £6 for the first, £10 for the second, and £15 for the third year. The trade schools for girls generally have a two years' course, and the value of the scholarships is £8 for the first and £12 for the second year. Unsuccessful candidates who do not obtain scholarships may be awarded free places. For other pupils a low fee of generally 10s. a term is charged.

No candidate is eligible for a scholarship whose parents or guardians have an income which exceeds £160 a year from all sources.

The special features of the London Trade Schools are:—

(1) The assistance given in the direction of the trade teaching by consultative committees of business men and women engaged in the particular trades for the training in which the school provides.

(2) The appointment of After-Care Committees, the members of which interest themselves in the scholars and advise them with regard to employment at the conclusion of the school course, and afterwards see that the conditions of their employment are satisfactory.

(3) The continuance of the general education of the pupils, only about one-half to two-thirds of the school time being given to actual workshop instruction.

(4) The prominence given to art instruction, not only in the technical requirements for the particular trade, but for the general development of a high standard of taste.

(5) The employment of teachers who have attained distinction as practical workers, and who approximate the instruction asfar as possible to workshop conditions.

(6) The holding of exhibitions of students' work to which employers are invited and at which offers are frequently made for the employment of students.

Trade schools for boys have been established in engineering, silversmithing, bookbinding, furniture and cabinet making, carriage building, art woodcarving, and various branches of the building trades. The trades for which schools have been established for girls are trade dressmaking, laundry work, upholstery, ladies' tailoring, waistcoat making, corset making, millinery, designing and making of readymade clothing, and photography.

* Abstract of a paper read by Dr. C. W. Kimmins before the Educational Section of the British Association at Winnipeg, 1909.

The development of trade schools in London is proceeding rapidly. The competition for the scholarships is becoming keener every year, and the work of the students is finding increasing favour with employers. No difficulty is experienced in finding suitable employment for boys and girls who have passed through the schools successfully.

TRIPOLI OSTRICH FEATHERS.

The trade in ostrich feathers is an important item in the commerce of Tripoli, in Barbary. The feathers are brought overland, from Central Africa, by caravans, and are then exported to Paris and London. One of the largest dealers in Tripoli estimates the value of the annual average imports from the interior at £20,000. The exports to Paris and London in 1905, 1906, and 1907 were valued respectively at £12,000, £11,000, and £10,000. The usual kinds of ostrich feathers known to the trade come into the Tripoli market. These are whites, blacks, feminas, byocks, spadonas, boos, drabs and floss. The Arab dealers bring them in unsorted packages, containing feathers in various qualities of each kind, and it therefore requires expert knowledge to buy advantageously from the natives. The goods are sold in Tripoli by the "rotl" (the Tripoli "rotl" is about eighteen ounces). The feathers are washed and sorted, but are not dyed or curled. They are washed in soapy water, and when still wet, are beaten. A handful of them is taken by the stems, and slapped against the floor with a force that, to the uninitiated, would seem to be enough to break them to pieces. This is done, according to the American Consul at Tripoli, to bring out the flues or barbules, the miniature feathers extending from the barbs, and to give the plumes a fluffier, richer appearance. A good ostrich plume will have two or three layers of feathers, its tip should be perfect, and it should have no transverse cuts along the vane. For the retail trade, two plumes are usually mounted together. A large quantity of Tripoli feathers come from ostrich farms in the Kanu district. The finest feathers which bring by far the best prices come from the Wadai and Darfur districts, and are taken from wild birds. The prices in Tripoli are to a certain extent influenced by the London and Paris markets. The contents of the original packages differ largely in kinds and qualities, and as the feathers are bought by the package, the prices, of course, vary largely. Some idea of the Tripoli prices may be obtained from the following quotations:—Whites and blacks (parcel containing twenty per cent. whites and eighty per cent. blacks) four shillings and eightpence per "rotl" of eighteen ounces; drabs (parcel containing seventy-five per cent. drabs, the balance being feminas, spadonas, byocks, &c.), two shillings and fourpence per "rotl" of eighteen ounces. The caravans usually begin to come in from Central Africa during the month of April and June. July and August are the best months for the trade.

ARTS AND CRAFTS.

The Arts and Crafts Exhibition Society.—The announcement that the Arts and Crafts Exhibition Society will hold its ninth exhibition in London early in January and will return to its old quarters at the New Gallery, will be good news to artists' craftsmen and craftswomen who have something to exhibit which aims higher than the greater part of the work to be seen at the small shows held under other auspices throughout the year. To those interested in the modern craft movement, it is interesting in more ways than one. It recalls the fact that only twenty-one years ago the expression "arts and crafts" was practically unknown and conveyed absolutely no meaning to the man or woman in the street—who, when it first opened, had no idea at all what to expect from an exhibition so strangely labelled. It is further somewhat of an object-lesson in the changes which come imperceptibly in the meaning of words. Arts and crafts to the founders of the Society did not mean by any means what the words naturally bring to our minds to-day. Indeed, the men who promoted the first exhibition were not, with a few exceptions like William Morris, Mr. de Morgan, and Mr. Cobden-Sanderson, craftworkers in the modern sense of the term. And, though a certain amount of embroidery (mainly by the wives, daughters or friends of members of the committee) was to be seen on the walls, the bulk of the exhibits consisted of work executed by well-known firms of paperstainers, glassworkers, metalworkers, or whatever they might be; work, in short, which differed from the ordinary ruck of trade production because it was designed by competent artists and executed by good workmen trying to do their best, but not in being the output of an artist turned craftsman for the nonce, or of handicraftsmen working and exhibiting on their own account. It was insisted upon at these early exhibitions that the name of the designer of the objects shown should be given—a rule which made some firms refuse to exhibit—but it was rather the exception to find the name of the executant mentioned at all. This may have been, and probably was, due in part to the prevalence of a somewhat different standpoint among the members of the committee from that of to-day; but the mere fact of the change which has come over the point of view is proof of how much the Arts and Crafts Exhibition Society has done since its formation to further the cause of art and handicraft in this country.

Before the Society's first exhibition the "artist-craftsman" was almost an unknown species—to-day he is to be found in every street. It is true, of course, that William Morris had been at work for years before the first Arts and Crafts Exhibition, that there was at least one guild of craftsmen in London, and that pioneers like Mr. Cobden-Sanderson were already working at an artistic trade; but it was the opportunity for designers and skilled workmen to show their work under their own names, to get to know each other and see what other folks similarly

engaged were doing, together with the opening of the eyes of the public which resulted from such an exhibition, which really made it possible for the artist-craftsman as we know him to-day to exist at all. If some old-fashioned workmen think that we got along quite as well, if not better, without him, they must remember that he is after all of very recent creation and must be given time to find not only his level, but his own feet.

Women and the Artistic Crafts.—In view of the numberless women practising various artistic crafts to-day, it is rather curious to note that no woman's name appears in the list of the first promoters of the Arts and Crafts Exhibition Society, and that, though there were quite a number of women exhibitors at the first exhibition, the overwhelming majority of them showed only embroidery or needlework of some kind. Indeed, no woman's name occurs amongst the members of the committee until 1903, though as early as 1889 there were three women members of the Society —Mrs. de Morgan, Miss Faulkner, and Miss May Morris. Facts like this help us to realise how really new are the woman bookbinder, the woman jeweller and silversmith, and others whom to-day we take as a matter of course. There have doubtless been women craft workers of various kinds from very early times. In the days when craftsmen worked at home no doubt the female members of the family were often employed in the work in different capacities as a matter of course; but the craftswoman of the present day is really a product of the twentieth century and of the very last years of the nineteenth. She is generally part artist, part workwoman, and part, it must be admitted, shopwoman. She designs her own work, makes it herself with the aid, perhaps, of a few pupils and apprentices, and sells it herself—either at her own "studio" or through exhibitions and other agencies.

It is in the capacity of tradeswoman that she has at times brought discredit on her calling, and rather justified the kind of sneer with which some people are wont to talk of "women's work." Naturally, craftsmen and women, like other folks, produce to sell, and some of them (many of them, in fact, both men and women) would find themselves in a very tight place if they did not dispose of their wares. There are women craft-workers who have always rated their work at its full value, and let would-be purchasers take it or leave it as they liked. But, still, it is, in the main, in their methods of selling their work that women have so largely failed. Of course, except in embroidery, a woman is heavily handicapped. She cannot, as a rule, get taken on in, say, a bookbinder's, a jeweller's, or a silversmith's workshop—and so, whether she has capital or not, she is practically forced to set up a studio of her own, and get along as best she can by giving lessons and working on her own account. Still, the fact remains—and it is to be deplored—that the ordinary woman-worker has been so anxious to dispose of her work, no matter how or where, that she has led many people to look upon woman's work in the artistic crafts as something about on a level with the kind of thing usually associated with bazaars. This is the more to be regretted because there exist many competent craftswomen whose position really suffers from the action of their less competent—or sometimes only less wise—sisters.

The Women's Work Exhibition at Olympia.—The Women's Work Exhibition at Olympia hardly included as much craft work as the posters led one to expect to find there—and though it was in a sense "International," no very large proportion of the exhibits came from regions beyond the British Isles. The show of the Dansk Kunstflidsforening (the Danish Society for Artistic Handicrafts) comprised not only pottery, embroidery, lace, &c., from Denmark proper, but also a collection of work from Greenland, not the least interesting feature of which were the leather belts, &c., ornamented with patterns formed of tiny bits of coloured leather sewn on to them which looked, at first sight, like plaiting or bead work. This is probably a modern and rather less workmanlike version of the sort of woven leatherwork from the same region to be seen in the museums, but it is still very pretty and attractive. Another interesting foreign exhibit was that of the Sicilian Industries, consisting entirely of needlework. The drawn thread work and embroidery for blouses was especially good, and the coloured Welsh flannels and poplins with drawn work ornamentation were not only effective, but very much on the right lines. Drawn work on a coloured ground offers many more opportunities than the plain white work. On one of the stalls were a few specimens of Javanese weaving, amusing in design and very pleasant in colour.

Amongst the exhibits from nearer home, the quasi-celtic designs for embroidery, leatherwork, &c. shown on the stall of the Irish Decorative Art Association, were characteristic if a trifle weird. It seems rather a pity that the people who have had the happy idea of reviving the old Italian paper ornamentation, which we know so well on old reliquaries and the like, have not made better use of it. This kind of work is pretty when it is used for carrying out a really suitable design, but it is not every pattern by a long way which lends itself to execution in tightly rolled coils of paper, and there is no inherent charm in the material to hide the deficiencies of an inappropriate design. Miss F. M. Rimmington's jewellery was tasteful, well made and moderate in price. The Misses Tebbs showed some interesting *punto tagliato* embroidery in colours, and Miss R. M. Jacot some very good cane and Indian baskets. In short there was good work of all kinds—embroidery, weaving, basketmaking, jewellery, and what not, to be found in the exhibition, but it had to be picked out from amongst a good deal which was, to speak frankly, quite trifling. One cannot but feel that better work

would be done if the workers could afford to go on quietly, doing their own work without having to spend their energies on producing the kind of stuff which they think will sell at exhibitions of this kind.

CORRESPONDENCE.

MAHRATTA PLOUGH.

Sir George Birdwood, in his very interesting and learned "Mahratta Plough," the first part of which is given in the Society's *Journal* of the 17th instant, says of Sopara, that "the well-known tope here was recently shown by Messrs. Mulock and Sinclair, of the Bombay Civil Service, to be a Buddhist relic mound." It is, no doubt, true that these gentlemen made a conjecture to that effect, and Mr. Mulock gave help in the excavation. But I think, and I feel sure that Sir George Birdwood will agree with me, that it is due to the memory of the late Sir James Campbell, K.C.I.E., to point out that he, with the aid of Pandit Bhagwanlal, arranged for the excavation, personally supervised it, and thus verified the theory; at least, the main part of the credit for the actual discovery is due to him, whose zeal in matters of antiquarian interest was intense and unbounded. A detailed account of the *stupa* and its contents is given in Vol. XIV. of his *Bombay Gazetteer*.

The following part of the discovery remains to me a mystery, but it may be capable of explanation by some members of the Society expert in biology. There was found a live frog in the position thus described by Sir James Campbell—"inside of the central relic chamber, about eight feet below the stone coffer; that is, under about 22 feet of solid masonry, and with about 35 feet of solid masonry on either side of it." I saw the frog soon after it was brought to Bombay with the relics. It was so attenuated that parts were almost transparent, and the beating of the heart could be seen with the naked eye. It died four days after being removed from the *stupa*.

I understand that there are other cases of frogs being found in circumstances indicating a very long life, but this *stupa* is believed to have been constructed in the second century of the Christian era, and it is hardly credible that any animal could live for 1,700 or 1,800 years. Of course it is possible that the *stupa* may have been opened and re-closed after the original construction, but it is not conceivable that it would be re-closed with an amount of trouble and care which could be due only to reverence except by Buddhists, and although Buddhism apparently lingered in Thana longer than in other parts of India, it was certainly extinct at the beginning of the seventeenth century. The position must therefore have been unaltered at least some hundreds of years. Unless a frog can live for some or many centuries, the problem is how this frog or the germ of it could have got into the position described after such a structure was completed. J. MONTEATH.

Bellair, Charmouth, Dorset,
September 19th, 1909.

[There are numerous stories of toads (and if toads, why not frogs?) having been found embedded in rock, but they all lack verification, and are discredited by biologists. They are generally believed to be accounted for by the animal having fallen into some crevice or cranny, where it has been found.—ED.]

OBITUARY.

LORD TWEEDMOUTH.—Lord Tweedmouth, who died in Dublin on the 15th inst., was a member of the Society of over thirty years standing, though he never took any active share in its management. He was elected in 1876. He was born in 1849, and was at Harrow and Christ Church. He entered Parliament in 1880. In 1892 he became one of the Whips of the Liberal party, and held the office until his succession to the peerage in 1894. When his party came into power in 1905 Lord Tweedmouth became First Lord of the Admiralty. In 1908 he resigned this office, and became Lord President of the Council, but failing health soon compelled him to retire altogether from the public service.

QUESTIONS AND ANSWERS.

QUESTIONS.

"Can any of the members of the Society or readers of this *Journal* inform me through its columns the names of electrical engineering firms in or near London where an efficient training can be had in dynamo and motor construction, shop work, &c."—S. V. SETTI, care of Messrs. Willans and Robinson, Rugby.

[Any replies to this query should be sent direct to Mr. Setti.]

GENERAL NOTES.

THE IRON AND STEEL INSTITUTE.—The Autumn Meeting of the Iron and Steel Institute will be held in London from September 27th to October 1st, 1909. A number of papers will be read and discussed; visits will be paid to various well-known engineering works and other places of technical interest, and in the evenings social entertainments of various kinds will be provided. Further information may be obtained from the Secretary of the Institute, 28, Victoria-street, S.W.

Journal of the Royal Society of Arts.

No. 2,967. VOL. LVII.

FRIDAY, OCTOBER 1, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

THE EXAMINATIONS OF 1909.

The Society's examinations have now been carried on on their present system for a little more than fifty years. They were established in 1856. In 1857 the first provincial examination was held, and in 1858 the system was established under which local committees were appointed to supervise examinations worked from a single centre. From that date up to the present the examinations have been held on the same plan, with only such modifications and developments as were rendered necessary by the general progress in education, and the consequent demand for more stringent and more specialised tests. On two occasions, in 1871 and in 1879 it was proposed to discontinue the examinations, and on both the idea was abandoned, in consequence of pressure put upon the Council by local institutions.

From time to time, subjects have been dropped out as they came to be dealt with by other agencies, and new subjects were introduced to meet the demands of Commercial Education. On the whole, however, the original system still remains, and it has certainly stood the test of time remarkably well.*

Up to 1880 the examinations were free, and the Society expended a very large amount of money on their development. When in 1882 the idea of abandoning the examinations was given up, it was determined to try whether they could not be made self-supporting. It was believed that a fee of 2s. 6d. for each candidate would be sufficient at all events to prevent a serious loss. In practice this anticipation proved accurate, and from that date to the present, this fee has been charged.† When it was first determined upon, it was believed that it would serve to minimise the loss, and the Society was quite prepared to expend a certain amount annually on the examinations. But their enormous development during the past five and twenty years has enabled them, since the number of entries became large, to be carried on without loss, and in some years even to bring in a small margin of profit. Of course many departments of the examinations are still unprofitable. But the profit on those subjects for which very large numbers enter is just sufficient to make up for the loss on the non-paying subjects, and so long as the Society is not called upon to provide amounts which would be a serious tax upon its moderate resources, the Council are, of course, perfectly content to carry on a useful public work, without much consideration as to whether the actual result is a small profit or a small loss. That the work itself is useful and is appreciated by the public is made evident by the large numbers which now avail themselves of the examinations.

Previous to 1880, when the examinations were free, the largest number of candidates in any year was a little over 2,000. This number was reached and surpassed in 1890. During the next ten years there was a steady annual increase, till in 1900 there were nearly 9,000. The effect of the Technical Instruction Act of 1889 sent the numbers up in 1901 to over 13,000. In the following year there was a trifling increase. In 1903 they passed 16,000, in 1904 they nearly reached 18,000, and in 1905 they exceeded 21,000. In the next three years there was a moderate increase up to 22,000, and this year they have again shot up to more than 25,000. This growth of the examinations since they were re-organised in 1883 is shown in diagramatic form on page 945.

In last year's Report on the examinations it was stated that no great alterations had been made since the changes in the system which came into effect in 1905, and

* Those who are interested in the history of the Examinations, may refer to an account of their origin and progress given in the *Journal*, April 16th, 1909, vol. lvii., p. 431.

† A lower fee is charged for the Elementary Stage.

that it was not proposed to make any alterations in the Programme for the present year. During the course of the present Session some suggestions were made to the Council that it would be advantageous if the Examinations could be spread over a longer period, since it often happened that candidates were prevented from taking certain subjects because they were set down for the same day as others for which they desired to enter.

As it was evident that this was a question which affected the Local Committees rather than the Central office, the Council in April last addressed a circular to the Secretaries of all the Examination Committees, asking them to ascertain the views of their Committees as to the extension of time, and to report whether they thought if 9 or 10 days were available, instead of 5, it would be an improvement.

There were at that time nearly 400 Centres to whom the circular was addressed. A little more than a half of them replied. Of the replies, about one-fifth were indifferent, rather more than two-fifths were in favour of the proposed alteration, and rather less than two-fifths were opposed to it. The opposition of most of the objectors was based on the difficulty of providing Superintendents for the examinations, and also of making provision for the very large number of examinations which are now held throughout the country, most of them at about the same time. It may be added that of the replies from the more important Centres, a considerable majority were opposed.

The Examinations Committee very carefully considered the replies to the circular, and they ultimately determined to recommend to the Council that the result of the enquiries did not appear to justify any alteration in the existing system. This recommendation was adopted by the Council, and consequently it is not proposed to make any change in the length of the time-table.

In answering the circular, a great many of the Committees suggested that the work of the examinations would be very much facilitated if a single Superintendent could be permitted to supervise the examinations, when only a small number of candidates were present, instead of the existing rule being enforced, which requires at least two.

The Society's Committee therefore added to their recommendation a suggestion that the rule as to Superintendents should be modified, so that where the number of candidates did not exceed ten, a single Superintendent should be considered as sufficient. This suggestion was also approved by the Council, and the alteration has been embodied in the rules for next year's examinations.

The only other change of importance in the regulations refers to the syllabuses for modern languages. Up to last year the rule was that in all modern languages a student should be given a choice of translating passages of a scientific, technical, or commercial character. Last year, in consequence of a number of recommendations from Local Committees, it was determined to modify the syllabuses of the Advanced Stage of modern languages, so as to allow a student possessing a good literary knowledge of a language, without a familiarity with the technical terms of science or industry, to qualify. The change appears to have been appreciated, and was approved both by the students and the examiners. It has therefore been determined to extend it also to the Intermediate Stage. The syllabuses have accordingly been modified in the Programme for 1910.

The Council do not believe that this alteration will in any way lessen the commercial value of the examinations, since they are satisfied, as stated in last year's report, that a student possessing an advanced literary knowledge of a language, would be able to turn that knowledge to account in commercial pursuits, and that he would soon be able to acquire a familiarity with the technical terms required in the special branch of industry or commerce in which he might be engaged.

The examinations this year were held at 414 centres in the week commencing March 29th, and lasted from the Monday until the following Friday. The results were issued at the following dates:—Advanced Stage, June 17th; Intermediate Stage, July 19th; Elementary Stage, August 16th. Having regard to the very large numbers of papers to be dealt with, no prospect can be held out of the results being issued at earlier dates.

The Commercial subjects included, as usual Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Handwriting, and Modern Languages. The other subject of examination was Music, divided into Rudiments of Music and Harmony.

The Society this year awarded 34 Silver and 43 Bronze Medals, the former in the Advanced Stage, and the latter in the Intermediate. It also gave away money prizes to the value of

£118, besides the prizes, amounting in all to £30, provided annually by the liberality of the Clothworkers' Company.

The total number of candidates at the examinations of 1909 was 25,042 (Advanced, 4,777; Intermediate, 11,076; Elementary, 9,196). This is an increase of 2,535 upon the 22,597 candidates of 1908, the increase being distributed over all three stages (Advanced, 487; Intermediate, 1,038; Elementary, 920). The number of papers worked by these candidates was—Advanced, 5,433; Intermediate (including Theory of Music), 12,512; Elementary, 11,069, or 29,014 papers in all. In addition to this there were 65 Shorthand and Typewriting candidates at the Special Army Examinations. In addition to these, again, there were 656 candidates in Colloquial Modern Languages, and 392 in the Practice of Music. The total number of candidates who were examined in all subjects by the Royal Society of Arts during the year ending July last was, therefore, 26,157. A comparative view of the numbers examined during the last five years (1905-9) is given in Table A (page 940).

The considerable increase above noted (from 22,597 to 25,042 candidates) was spread over practically all the subjects of examination, the only subjects showing a decrease being Italian, Spanish, and Swedish, and even in these the difference was very trifling. Last year there were three candidates in Japanese and one in Hindustani. This year there are none in either subject, but for the first time Chinese appears on the list. It attracted two candidates. As has been the case for some years past, the greatest number of entries was in Book-keeping, which shows a total of 9,402 in all stages—nearly a thousand more than last year. The next largest number is Shorthand, in which there were 7,480 papers worked—an increase of about 600. French comes third. This subject has shown a steady increase of recent years, the numbers being 3,287—an increase of about 500 over last year, and 1,200 over 1905. It is satisfactory to note that this subject is now attracting so large a number of candidates. It is also satisfactory to record a steady advance in Arithmetic. Not many years ago in reporting on the examinations, attention was drawn to the fact that this, among the most important of all subjects, did not receive a due measure of attention. This year there were 2,185 candidates, of whom the largest proportion (1,393) were in the Elementary Stage; last year 1,788 entered. It is still to be desired that more candidates should enter for Arithmetic in the two higher Stages, especially in the Intermediate. Another popular subject is Typewriting. This year there were 2,092 candidates, of whom just half were in Stage I. Last year there were 1,909.

The above are the only subjects attracting such large numbers, though nearly a thousand (precisely 982) entered for Handwriting and Correspondence in the Elementary Stage. For German there were 835 candidates; last year there were 740. This is a good proportionate increase, which shows itself in all the stages. For English there were 423 candidates—349 in Stage II. and 74 in Stage III. This is an increase on the 353 candidates of last year. For Accounting and Banking there were 369; last year there were 288. Commercial History and Geography, taking all three Stages together, produced 370 candidates, last year there were 344. The increase here was in the upper Stages, in the Elementary (which does not include History, there was a decrease). In Economics there were 138, as against 105. Précis-writing 169—last year 152. Commercial Law has only a nominal increase—216 against 214. Spanish, as mentioned above, shows a slight falling off. There were only 240 candidates this year—last year there were 259. In Portuguese the numbers are actually equal—34; and there were in both years 9 candidates for Danish and Norwegian. Thirteen candidates came up for Russian; last year there were 8. Eight entered for Swedish and 13 last year. The two candidates for Chinese both passed in the Intermediate Stage. The numbers of papers worked in all the different subjects of the three Stages are given in detail in Table G (page 943), while Table B (page 941) gives the numbers of papers worked in each subject in the two higher Stages in each year from 1905 to 1909 inclusive.

While the increase in the candidates in Stages III. and II. is very satisfactory, as much can hardly be said of the character of the papers. So far as can be judged by percentages of failure and success, the increase in numbers does not seem to be accompanied by improvement in quality. The percentage of failures in Stage III. in many subjects show a decline from the average, and are generally higher than last year. In Shorthand, the percentage of failures (75 per cent.) is very high indeed, much higher than it ought to be. But it may be taken as fairly certain that the standard has not been raised, and it may be added that a very careful revision of the papers made it quite clear that it would be impossible

without a serious lowering of the standard, to pass any of those who failed. The reason for this is certainly that candidates insist upon entering for a much higher speed than they are capable of taking. If many of those who had entered for the Advanced Stage (140 and 120 words a minute) had been content with the Intermediate Stage (100 and 80 words a minute) they would certainly have passed; and in the same way a proportion of those who failed in the Intermediate Stage (though here the failure percentage was lower) might have taken the easier certificate in the Elementary Stage, and deferred for another year the more difficult one in Stage II. At the same time it may be remarked that the percentage of failures in Shorthand examinations always seems a good deal higher than the usual percentage failure, which as a rule may be expected to be about 33·33. In Arithmetic also there is a distinct falling off from last year, and so there is in Commercial History and Geography. This was noticed by the examiners. On the other hand, though there was a large percentage of failures in Précis-writing, there was improvement in the general character of the papers. In all the modern languages there is progress. There are generally less failures, and the work is better.

And it must be borne in mind that the quality of the papers must not be wholly judged by the percentage of failures and successes. This percentage is lowered by the larger number of inferior papers. The quality of the work of those at the head of their class remains the same. Every year there is sent in, in many at all events of the subjects, a certain proportion of work of a genuinely brilliant character. There are very often a few papers which stand out from the rest by their superiority. To some extent these are marked by the award of medals, but often they could only receive their due credit if they were placed in a class by themselves.

With regard to Stage II., the percentages of failure in all subjects do not differ very widely from the usual average of recent years, though they are higher than last year. The proportion of First-classes is distinctly low, and, on the whole, the work was hardly up to the standard of recent years. In English there was improvement. In Book-keeping the character of the papers showed a falling off, and there was too large a percentage of failures. In Typewriting the standard was not maintained. The same may be said of modern languages generally; in German the papers were, on the whole, worse than they have been for some years. In the whole of Stage II. it may be said that the work was below the average, and much below the standard of last year, when the papers altogether reached a fairly high level.

Table C (page 942) and Table D (page 942) show the percentages of failures and successes for all subjects in the two upper stages for the present year. The number of entries in some of the smaller subjects is insufficient for such calculations to have much value, but the percentages are given for the sake of completeness.

Table E (page 942) gives percentages of successes and failures in all three stages for the last five examinations.

In the Elementary Stage, a marked and steady improvement is evident, indicating progress in the character of the teaching, and in the attainments of the candidates. This stage has shown distinct progress in every way since its establishment in 1901, and affords very distinct evidence of advancement in the class of instruction given in the secondary schools of the London County Council, and other educational authorities throughout the country.

Table F (page 942) shows the progress made by the Elementary Examination since the Stage was established in 1901. It gives the number of candidates in each year with the number of papers worked; also the number of subjects of examination.

In the Elementary Stage the 9,196 candidates worked 11,069 papers, so that, as is always the case, a large proportion of the candidates in this, as in the higher stages, were content with a single subject. Book-keeping attracted the largest number, 3,340; next was Shorthand, 2,443. The next largest subject was Arithmetic, for which there were 1,393. In French, there were 1,258. Then comes Typewriting, for which 1,010 candidates presented themselves; in Handwriting and Correspondence, 982. In German the numbers were 348. In Commercial Geography 246. Spanish attracted 61 entries, and Italian 18. In all 7,366 certificates were granted to successful candidates, and there were 3,703 failures. It is gratifying to notice that with the considerable increase of numbers there has been a remarkable increase in the percentage of success. Commercial Geography shows a falling off of 30 from last year; in Spanish there are 17 less, and in Italian 7. All the other subjects show an increase.

Table G (page 943) gives in detail the results

of the present year's examinations. It gives the number of papers worked in each subject in each stage, with the corresponding successes and failures.

Two fresh Tables have been added to this year's Report — Tables H and K on page 944. They show the proportion of failures in each subject in the two higher stages at the examinations of the last five years, including the present year. Their object is to indicate, as far as such figures can indicate, the general standard which it is attempted to preserve in each stage. It is of course impossible to establish identical standards for different subjects. No one could say what would be an identical standard for Arithmetic, Book-keeping, Shorthand, and French. Still it is possible by the aid of experience to approximate to a similar standard, even in subjects of a totally different character, and it may be taken as certain that the same standard is fairly well preserved in each particular subject. The results of necessity vary from year to year, and it is generally the case that when there is anything like a sudden increase of numbers in a subject, the proportion of failures increases.

It may also be said, as is mentioned in another part of this report, that when the numbers upon which the percentages are based are small, the percentages themselves are practically meaningless. In those subjects in which there are only a very few candidates, no useful conclusion of any value, for purposes of comparison, can be drawn. Another point worth mentioning is that the standard is purposely kept rather lower in subjects for which there are very few entries, and which therefore seem to require encouragement. In such subjects as Russian, Danish, Swedish, Chinese or Japanese, the standard to which the candidates are expected to work has no sort of relation to the definite standard which has been established by long experience in the more popular subjects.

A report on the Practical Examinations in Music has been published in the *Journal*.* 392 candidates were examined—a decrease of 40 as compared with the 432 last year; of these 298 passed and 94 failed. These examinations have been carried on continuously since they were established in 1879. The numbers have never varied very widely. In the first year 117 candidates were examined. The numbers increased gradually to 276 in 1891, and to 393 in 1895. The largest number yet examined was 566 in 1900. During the last few years there has been a small but steady diminution in the numbers, the reason for which is not very apparent. The standard has not varied greatly, but is now a little higher than it was. The general level of attainment is considered by the examiners to have risen slightly of recent years.

* See *Journal*, July 9th, 1909, vol. lvii., p. 696.

For the Vivâ Voce Examinations held this year in Modern Languages 656 candidates entered—a slight increase on last year, when there were 613. These examinations were started in 1902, when 280 candidates were examined. The numbers rose to 681 in 1904, after that there was a slight falling off. Examinations were held this year in French, German, Spanish, and Italian; there have also in previous years been a few entries for Portuguese, but none entered this year. The numbers were—French 472, German 146, Spanish 25, Italian 13. The increase is principally in German, for which last year only 100 entered, whereas there were 146 in 1909.

The Examiner in colloquial French reports that with a slightly larger number of candidates, the percentage of successes is higher, though fewer passed with distinction. The German examiner speaks favourably of his results—102 out of 146 having passed, 32 of them with distinction. Spanish is, as last year, less satisfactory, 13 only out of 25 having passed, and only 1 with distinction. This result is unexpected, seeing how successful the written examinations in Spanish are. It is to be regretted that more of the successful candidates do not take up the study colloquially. The Italian examiner remarks on the fluency with which most of the candidates spoke. There were only 13 candidates, of whom one failed.

A report containing further details of these examinations, giving a list of the places where they were held, &c., will appear in a forthcoming number of the *Journal*.

It is much to be desired that these ~~colloquial~~ examinations should attract a larger number of candidates. Facilities for the acquirement of a conversational knowledge of foreign languages are now more abundant than formerly, and the independent test provided by the Society's examination must of necessity be useful. The certificate also must be valuable evidence of proficiency. It should be noted that these examinations are offered to students at, or probably under, their actual cost.

The examinations in Rudiments of Music and Harmony were carried on as usual at the

same time as the Commercial examinations, and the results appeared as part of the results of the Intermediate Stage. The total number of candidates shows a slight falling off as compared with last year, though a slight increase on the previous two years. This year there were 699, compared with 716 in 1908, 641 in 1907, and 632 in 1906. The falling off was in the first-named section, there being a small increase in the second. In Rudiments of Music 455 candidates presented themselves, whereas last year there were 482. In Harmony there were 244, as compared with 234. Of the 455 candidates in Rudiments of Music, 380 passed and 75 failed. Of the candidates in Harmony, 183 passed and 61 failed. The examiner, on the whole, reports favourably on the results, and indeed the proportion of successes to failures was much higher this year in both divisions of the examinations.

At the request of the Army Council, the Council in 1907 arranged to hold a special annual Examination in Shorthand for soldiers. The first examination in Shorthand was held that year, when, out of 40 candidates entering, 26 passed; the second was in April, 1908. There were in all 84 candidates, of whom 67 passed and 17 failed. A silver medal was awarded to the best candidate in the Advanced Stage.

This year the entry was not so large, there being only 60. There were 30 centres in the United Kingdom, India, South Africa, and Egypt. These examinations this year, as last, were held in April. Of the 60 candidates, 41 passed and 19 failed. In the Advanced Stage there were 2 First-class and 11 Second. In the Intermediate Stage there were 18 First and 15 Second. Though the results are not as good as last year, the percentage of successes, 75, is above the average. Last year it was 77.

Last year, also at the request of the Army Council, similar examination for soldiers in Typewriting was arranged. There were only 5 candidates, and 4 of them passed, 1 Advanced, 2 Intermediate, and 1 Elementary Grade. The solitary failure was in the Elementary Grade. The examinations were held at 3 centres in the United Kingdom. This year there were again 5 candidates, 2 in the Intermediate, and 3 in the Elementary Stage. All passed, the two in Stage II. securing First-classes. All the work was good. The Examinations were held at 4 centres in the United Kingdom and India. As the number of entries are so few, it is not intended to continue the Typewriting examinations.

The Examination Programme for 1910 was issued three weeks ago. In it will be found the fullest possible information about the Examinations, a Syllabus of each Stage of each subject, and the papers set in 1909. The attention of both teachers and students may be drawn not only to the Syllabuses but also to the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them. Teachers especially should study these remarks, and be guided by them in the instruction they give to their pupils. The remarks of each examiner follow his examination paper in the Programme for each year.*

* The price of the Programme (128 pages) is 3d., post free 4½d. Copies can be obtained on application to the Secretary of the Royal Society of Arts, Adelphi, London, W.C. Programmes containing the papers set in 1905, 6, 7, 8 can also be obtained at the same price.

THE RELATIONSHIP OF MANURING TO MEAT PRODUCTION.*

It has long been known that a large increase of herbage is secured from many classes of grass land through the use of certain artificial manures, but in most cases the effects of the manures have been tested by simply weighing the increase secured. Sometimes the investigation has been carried further, and the herbage grown with and without manure has been separated into its constituent plants, and an attempt has been made to estimate the improvement in quality by the increase of such plants as clovers, and the suppression of such plants as sorrel and other weeds. In addition to such a botanical separation the herbage has sometimes been submitted to chemical analysis, and an attempt has been made to gauge the feeding value by the percentage and absolute weight of proteids, fats, and carbohydrates, and by the digestibility of the fibre. All these methods convey useful information, but as the ultimate object of producing herbage is to feed animals, and as no laboratory method can perfectly interpret the processes in an animal's stomach, it occurred to me that useful information might be got by utilising the animals themselves to pass judgment on the results.

My work has been chiefly confined to experiments on grass-land, and on grass-land they have been chiefly concerned with pasture as opposed to hay. In the United Kingdom there are some 34,000,000 acres under grass (apart from mountain grazings), and of this, 24,000,000 acres are grazed and 10,000,000 are cut for hay. Clearly, therefore, the grazed area is of much more importance than that which is used for hay. To exclude stock from plots on a pasture, and to test the results of applying manures by weighing and analysing the herbage, must lead to a fallacious conclusion, for the reason that the mere exclusion of the stock encourages one set of plants and represses another, and the experiment resolves itself into one not on pasture, but on hay.

In 1896 the county of Northumberland rented a farm (Cockle Park) of 400 acres, of which I was given the scientific direction. A clay-field of uniform character, that had been under pasture of a poor type for many years, was divided by fences into ten plots of $3\frac{1}{10}$ acres each. Three acres of each plot had been grazed by sheep each summer for the past thirteen years, the herbage of the sub-plot of $\frac{1}{10}$ acre being annually made into hay. Specially selected sheep have been used for grazing the plots, the animals being individually weighed at the beginning of each season, and monthly during the progress of each grazing season. The health of the sheep on the comparatively limited grazing area of three acres has been all that could be desired, and any individual idiosyncracies have been eliminated by the number of sheep (usually six to twelve) that grazed each plot. The system of experiment ("manuring for mutton") and the results have attracted a large amount of attention, and, aided by the Board of Agriculture, the experiments have been repeated, in part or in whole, in several parts of England and Scotland. It is only necessary here to call attention to the leading results, and chiefly to those obtained during the first nine years, the scheme being primarily designed to cover that period.

Lime has been used in two ways: (1) In two dressings of 4 tons per acre, and (2) in three dressings of $\frac{1}{2}$ ton per acre as a supplement to superphosphate. The former system is a very old one and popular with farmers, but neither at Cockle Park nor elsewhere have the experiments shown it to be efficacious or profitable. At Cockle Park it only accounted for an average annual live-weight increase (which, for short, may be called mutton) of 12 lb. per acre. Under the second method the $1\frac{1}{2}$ tons of lime have produced an average annual increase of 22 lb. of mutton, and have left a small profit, as against a large loss in the other case. Basic slag, used in the first year only, at the rate of 10 cwt. per acre and a cost of 23s. 6d., has produced an average annual increase of 80 lb. of mutton. Valuing this at $3\frac{1}{2}$d. per lb., and deducting the cost of the manure, it means that a single expenditure of 23s. 6d. has given a clear annual gain of 22s. 3d., or nearly 100 per cent. per annum, and even at the end of nine years the effects of the slag are by no means exhausted. On an adjoining plot 10 cwt. of basic slag had also been used, 5 cwt. being put on the first year and 5 cwt. at the end of the third. This method of treatment has produced an average increase of 66 lb. of mutton, and although the profit here has also been large (averaging 18s. per acre per annum), it is considerably short of that secured under the other method of using the same manure. This result has been confirmed at the other duplicate stations, and shows that it is better to stimulate the superior plants by a large initial dose of phosphates than to spread the use of the phosphates over a longer period.

When the source of phosphoric acid was superphosphate instead of basic slag the cost was considerably greater, and the actual weight of mutton produced was distinctly less (57 lb. per acre per annum as against 66). The annual profit was therefore reduced from 18s. to 13s. 9d. per acre.

Adding potash to phosphate increased the yield of mutton to the extent of just covering the outlay involved.

When nitrogen in the form of sulphate of ammonia was used the yield of hay was increased some 25 per cent., but the annual production of mutton was actually reduced from 57 to 54 lb. per acre per annum. This result was also obtained at all the stations, and shows how far mere weighing of the herbage may lead one astray.

Other manurial substances (cakes, residues, and dissolved bones) were also tried, but the results of

* Abstract of a paper read by Professor Somerville before the Agricultural Sub-Section of the British Association at Winnipeg, 1909.

these, being more complicated, need not be discussed. Mention may, however, be made of the fact that at Cockle Park at the end of the ninth year a further dose of 10 cwt. of basic slag was applied per acre to the plot that had received a similar dose nine years previously, and the effects were seen in a large increase of mutton in the following years (1906, 1907, and 1908). This proves that there is little ground for the popular belief that grass-land fails to respond to a second application of a phosphatic manure. At one of the duplicate stations basic slag was applied to a plot in the middle of June, and before the grazing season was over the effects were clearly reflected in the growth of the sheep and in the appearance of the pasture. In the following year this plot, which had been the worst of the series, became the best. The opinion hitherto held that an insoluble phosphate, like basic slag, should be applied some months ahead of the growing season, must therefore be revised, equally good results following application when the herbage is in vigorous growth.

These experiments seem to show that probably no crop on the farm offers opportunities for more profitable use of artificial manures than poor worn-out pasture.

MARBLE WOOD OR ZEBRA WOOD.

The Government of India are issuing a series of short monographs dealing with some of the more important India timbers, and one entitled "Andaman Marble Wood or Zebra Wood" (*Diospyros Kurzii*, Hiern), by Mr. R. S. Troup, F.C.H., Imperial Forest Economist to Government, supplies information about a valuable product but little known in this country. The tree, which is an evergreen, is distributed throughout the Andamans, and is also found in the Nicobars and Coco Islands, in semi-deciduous and evergreen forests at elevations of about 50 to 200 feet above the sea. It grows to a height of from 40 to 60 feet, and a girth of 5 or 6 feet. Like the "calamander wood" of Ceylon, marble wood is a variegated ebony, the chief value of which for ornamental purposes lies in the remarkable effect produced by alternating streaks of black and grey. Mr. Troup sent samples of the wood to Mr. Herbert Stone, of Birmingham, the well-known specialist on timbers, and the latter reported that the wood was well-known in England to turners and makers of "Tunbridge ware," but that it is surprising how rarely one sees it in use. Mr. Stone could not recall having seen a piece of furniture in which marble wood was used. Nevertheless it is highly spoken of by men in the trade, and there can be no doubt that all that could be sent over to England would be readily bought up. The greater the contrast between the darker and lighter bands the more valuable would the timber be. It is a true turner's wood and when polished has a very fine effect. Altogether Mr. Stone and the experts he consulted considered it one of the handsomest timbers in the world. In the present monograph there are photographic illustrations of fifteen specimens, and one can quite realise the statement that the wood readily takes a high and fine polish. In seasoning it requires great care, but the marble wood planks received by the author from the Andamans have shown less tendency to warp and split than many other Indian woods. A small trial consignment of 8½ cwt. sold a great many years ago in London fetched at the rate of £2 15s. per ton weight, but regular consignments at the present time would probably bring a much higher price. The forests of the Andamans and other islands being practically unexplored it is impossible to estimate the future out-turn. At the same time it might prove well worth while exploiting the woods, for so handsome a wood is peculiarly suitable for cabinet work, ornamental furniture, walking sticks, fancy-boxes, carving, turning, inlaid work, picture frames, &c. Enquiries regarding the timber should be addressed either to the Deputy Conservator of Forests, Port Blair, Andamans, or to the Imperial Forest Economist, Dehra Dim, United Provinces, India.

ORIENTAL STUDIES.

The Report of the Committee, appointed by the Treasury as far back as April, 1907, to consider the organisation of Oriental Studies in London, was issued as a Parliamentary Paper (Cd. 4560) on the 25th inst. A very full report of it appears in *The Times* of the 27th.

The Committee recommend the establishment in London of a School of Oriental Languages, under the control of the University of London. The estimated annual cost of the proposed school is £12,725 a year, and an initial grant is also suggested. The staff proposed includes a director, five professors, nine readers, sixteen native assistants, librarian, secretary, &c. The languages in which it is suggested that instruction should be given in the first case are Turkish, Arabic, Persian, Hindi, Hindustani, Bengali, Marathi, Gujarati, Tamil, Telugu, Kanarese, Burmese, Malay, Chinese, Japanese, Swahili, and Hausa; and it is suggested that later on instruction may also be required in Assamese, Punjabi, Tibetan, Pashto, Cinhalese, Melanesian and Polynesian languages, Siamese, Amharic, Luganda, Somali, Yoruba, and Zulu.

Attention may be drawn to the fact that for many years past this Society has endeavoured to encourage the study of Oriental languages by offering to hold examinations in them. Syllabuses have been prepared, and issued in the Examination Programme, for Japanese, Chinese, and Hindustani. Medals and money prizes have been offered in each subject. Nevertheless the number of candidates has been absolutely insignificant. For many years there were

none at all, and during the past five years or so there have been only one or two candidates in each subject. The response to the offer having been so extremely poor, the Society has never been encouraged to organise examinations in other Oriental languages, though it certainly would have been prepared to have done so had there been any probability of an adequate response. It is to be remembered that the examination of one or two candidates involves a pecuniary loss, since the expense incurred is very much the same as for a larger number.

THE EVOLUTION OF A BREED OF CATTLE.*

Nearly every breed of cattle is a combination of several breeds: a result of crossing again and again and of subsequent "pure" breeding. The modern Aberdeen-Angus breed is a case in point. It is the result of perhaps fewer crossings than some other breeds; but the ingredients used in its production are so decidedly varied, that a consideration of the way in which it has been formed yields the most highly instructive results.

In addition to the Urus, which became extinct in the Bronze Age, half a dozen different kinds of cattle have come to Britain at different times—viz., (*a*) the black Celtic race, which came in before the Urus was extinct; (*b*) the "brown" race, black with a brown stripe along the back and a tan muzzle, which probably came with the Belgæ; (*c*) the white race, brought in by the Romans; (*d*) the red race, brought in by the Anglo-Saxons; (*e*) the hornless race, brought in by the Norsemen; and (*f*) the large flecked race imported from Holland in the seventeenth and eighteenth centuries.

When the Norsemen brought over their hornless cattle the rest of Scotland was occupied by the black Celtic race, with a considerable infusion of brown Belgæ and a smaller infusion of white Romans. These were all horned. In the eighteenth century many large cattle of the Dutch flecked race were taken to the North-East of Scotland and crossed with the small native cattle, with the result that the native cattle gradually acquired the size of the flecked cattle. All this time the Norse cattle had been holding the sea-boards of Forfar, Kincardine, Aberdeen, and Banffshires. In the middle of the eighteenth century a demand arose in England for hornless cattle; and to meet this demand the farmers in the North-East of Scotland crossed their horned cattle with the Norse hornless ones, with the result that the horns of the horned ones were removed. By selecting breed stock that were black in colour, large in size, and hornless, the North-East farmers eliminated the undesirable characters of the various races of cattle that had been introduced to their country, and eventually produced their present breed.

* Abstract of a paper read by Professor J. Wilson, B.Sc., before the Agricultural Sub-Section of the British Association at Winnipeg. 1909.

HOME INDUSTRIES.

The Insurance of the Poor.—The opposition to the Assurance Companies Bill grows, and it may be hoped that the Government will not press it through the House of Commons this year. It has passed the House of Lords, but Lord St. Aldwyn and other peers expressed considerable doubt as to whether it was well considered. Lord St. Aldwyn spoke of it as a "whitewashing Bill," and that accurately describes it, in so far as it relates to industrial insurance. As all know, there are great abuses in connection with this branch of insurance business. Large sums are taken from the working-classes every year by industrial insurance companies, who give a very inadequate return, or none at all. In a case recently before the Courts it was proved that the plaintiff had paid over £91 in return for a possible £35. For loans, where it is impossible for the company to lose, as much as 10 per cent. interest is charged. In the case of policies where there is no insurable interest some of the companies instruct their agents to fill in the object of the insurance as "funeral expenses;" and the agents do not hesitate to forge the signatures of persons upon whose lives assurances have been proposed without their knowledge by other persons. In one case tried during the past summer, forging of the signature of the person who was insured by the agent, and absolute ignorance by the assured until many years after, were proved. The company went to the Court of Appeal, which, without hesitation, dismissed the appeal with costs. In his judgment the Master of the Rolls, referring to the agent concerned, said, "Now what is the position of this man? He is a superintendent of the company, and he is appointed under the terms of a written appointment containing a clause which puts a temptation in the way of a superintendent to which a superintendent ought never to be exposed. It is part of the terms of his appointment that it is his duty to increase the business of the company in his superintendency not less than 6s. per week. That is a frightful temptation to put in the way of a superintendent, and an inducement to him to go, as this one did to the plaintiff, and to obtain a proposal from him regardless whether there was any 'insurable interest.'" It is not too much to say that there are hundreds and thousands of industrial insurance policies taken out every year that are fraudulent, policies where the signatures are forged, policies where there is no insurable interest, policies taken out owing to all sorts of false representations. The Attorney-General recently admitted in Parliament that these abuses exist. Of course, the Insurance Companies' Bill now before the House of Commons will not legalise fraudulent representation of any kind, but if it becomes law it will make effective a vast number of policies that are now avoidable, and will legitimatise much of the gambling in lives that now takes place. It proposes to repeal the Act of George III. which prohibits insurance of lives when the persons insuring have no interest in the life

or death of the persons insured, and to extend to what experts consider dangerous lengths "insurable interest." The Parliamentary Committee of the Trades Unions are at one with Lord St. Alwyn in their distrust of some of the clauses of the Bill: lawyers are equally opposed to them; and it is much to be hoped that the Government will postpone the passing of the Bill, or at any rate the controversial clauses to which reference is here made, until a Select Committee has had the opportunity of examining and reporting upon them.

Agricultural Returns.—The Preliminary Statement for 1909 shows that the conversion of arable land into pasture, and the reduction of the agricultural areas, which have been such marked features of the last thirty years continue, but last year the shrinkage was smaller than in preceding years. The total extent of arable land which about thirty-five years ago amounted to 18½ million acres has now fallen to 14,730,668 acres (as compared with 14,795,517 acres in 1908). On the other hand the area under wheat shows marked increase, 1,823,563 as against 1,626,753 acres. The comparison is between 1909 and 1908, and it may be expected that with the continuance of high prices there will be a further increase in the coming year. The area under barley shows a slight falling off, 0·2 per cent., and under oats 4·1 per cent., but the acreage under peas increased no less than 20,171 acres, or 12·3 per cent. It is satisfactory to note that the area under small fruit continues to increase. In 1908 2,705 acres were added, and this year there is a further increase of 2,236 acres, or 2·6 per cent. The hop area continues to shrink. In 1908 the acreage of hops returned was 6,017 acres below that of 1907, this being the largest decline recorded in any year except 1887, when the loss amounted to 6,421 acres. This year the acreage has shrunk to 38,921 acres, the decrease as compared with last year being 6,382 acres, or 16·4 per cent. The number of pigs returned in 1908 was 2,823,432, being 186,716, or 7·1 per cent. more than in 1907, but this increase has now been much more than lost, the number having fallen to 2,380,887, or no less than 15·7 per cent. The changes in the other descriptions of live stock have not been important. The total of cattle shows a decline of 1·7, of sheep 1·8, and of horses 0·5 per cent.

The Wool Trade.—The present high prices for wool can hardly be maintained. Some of the largest users in the West Riding have decided not to order the purchase of a single bale in any of the Australian markets during the present season, or, at any rate, until prices have sensibly dropped from their present level. They prefer to risk the London market, and will only buy from hand to mouth. It is admitted generally that big increases are assured from all the sources of supply in the southern hemisphere. The chairman of the United Pastoralists' Association, of Queensland, in his address to the members, said that he considered the number of sheep in the State had increased by about 10 per cent., thus making the number upwards of 20,000,000. He anticipated that the highest record would be reached by the end of the year. Since the end of the great drought in 1902, the number of sheep depastured in Queensland has trebled, and as the breed of sheep has been greatly improved, it is to be assumed that the clip of wool has increased in a greater ratio than the number of sheep. Advices state that the sheep are cutting unusually heavy fleeces of sound, deep-stapled wool, and it should be borne in mind that an increase of only one pound in the weight of each fleece would mean an increase in wool exports from the Commonwealth of over 200,000 bales.

The Milk Supply.—Dr. A. G. Anderson, who has given many years to the investigation of the conditions of the cowsheds, dairies, and milk supply of Rochdale, of which town he is Medical Officer of Health, has published an important report upon the production and supply of milk from the point of view of health. One of his main points is that "the great source of contamination is the cowshed, the cow, the milker, and the utensils, and the only reasonable and logical solution is to remove the evil at its source by the establishment of a higher standard of cleanliness." Within the borough of Rochdale there are 75 farms providing milk. They contain 137 cowsheds with 1,207 cows and they are classified as follows:—good, 30; fair, 39; bad, 68. Dr. Anderson found that the larger the farm the better the conditions, for the average number of cows to each "good" cowshed is 13·33; to the fair, 10·74; and to the bad, 5·70. He believes that apart from and in conjunction with legislation much might be done by private enterprise and education, and he points to what has been done by certain companies in Denmark, in England, and in America. The farmers supplying milk to these companies have to agree to certain conditions of contract, for the contravention of which there is a heavy penalty, £100 in some cases. The cows have to be warranted free of disease and examined for tuberculosis by the tuberculin test; the conditions of cowshed, lighting, ventilation, cleansing, drainage, water supplies, cleanliness of milkers, cooking and straining milk, chemical and bacteriological tests, protection of milk from infection, and other standards are distinctly laid down, and to ensure that these conditions are observed the inspectors of the companies regularly visit the farms. Dr. Anderson recommends the institution in Rochdale of one of the depôts for the sale of milk which under the Milk and Dairies Bill the local authorities are authorised to establish; he believes that apart from the supply of good milk to babies it would educate public opinion, and act as an inspiration and stimulus to many farmers and dairymen who may care to learn the science of the business.

The Shipowner as Common Carrier.—Is the shipowner a common carrier? In theory yes, in practice no. The question is raised by Mr. Arthur Cohen, K.C., in one of the Appendices of the Report of the Royal Commission on Shipping Rings. It was, he says, established by Nugent *v.* Smith and other cases that a shipowner's liability at common law is the same as that of a common carrier, so that in the absence of any stipulation to the contrary a shipowner is bound to carry the goods safely, and deliver them at their port of destination, and is responsible for any loss or danger, the act of God excepted. But in practice this liability disappears, since the shipowner is free to enter into a contract with a single shipper, practically excluding any and every other shipper from the transaction. Mr. Cohen puts the law in this way:—"According, then, to English law, the shipowner's liability is, in the absence of argument to the contrary, that of a common carrier, which is substantially the same as that of an insurer of goods. A merchant can indeed require the shipowner to carry his goods, as, and with the liability of a common carrier, on tending to him a reasonable freight. In fact, however, no merchant ever desires or requests his goods to be carried on those terms, and would never tender the proper freight for the purpose." The law holds the shipowner to be a common carrier, but he is never asked to trade in that capacity, and so in fact he is not a common carrier.

CORRESPONDENCE.

EMPIRE NOTES.

I see in your September number a good feature entitled "Empire Notes." The States and Provinces of the Empire deserve to be brought forward on every possible occasion, and indeed are receiving much attention. I am particularly at present interested in Army Pensioners desirous of commuting their pensions and going to New Brunswick. I enclose note of an excellent scheme we have devised for their benefit. Officers, as well as non-commissioned officers, &c., can avail themselves of it. No other Government has offered anything so favourable.

W. M. Graham Easton,
Secretary.

Norfolk-house, Office of Agent-General for New Brunswick,
Laurence Pountney-lane, London.
September 27, 1909.

Mr. A. B. Wilmot, Superintendent of Immigration, St. John, N.B., to Mr. W. M. Graham Easton, Secretary, New Brunswick Agency-General, London. July 17, 1909.

Commuted Pensions.—I had a conversation with the Premier *re* this matter, and he agrees that there would be no difficulty about safeguarding the settlers' money. An arrangement may be made whereby the commuted pensions may be transferred to the office of the Receiver-General for New Brunswick, and have a separate account opened with each settler. Three per cent. interest will be allowed by the Government on the balance of all the money that is deposited. The Government will appoint a Board of three members, one of whom shall be a member of the Executive Council, upon whose recommendation money may be withdrawn by any pensioner for purposes approved of by the Board. It can be arranged with the Secretary of the Board to report to the Home authorities in regard to each pensioner, say every six months. The Board would naturally make every effort to get each settler located under conditions giving promise of the best results. If the pensioner decides, after remaining in the Province for a year, that he would prefer to locate in some other part of His Majesty's Dominions, the transfer of his property and effects can be arranged with the approval of the Home authorities. I see no difficulty in arranging for a perfectly workable system.

GENERAL NOTES.

Swiney Lectures on Geology.—A course of twelve lectures on "The History of North-West Europe during Tertiary Times" will be delivered by T. J. Jehu, M.A., M.D., F.R.S.E., in the lecture theatre of the Victoria and Albert Museum, South Kensington, on Mondays and Tuesdays at 5 p.m., and Saturdays at 3 p.m., beginning Saturday, 6th November. They will be in connection with the British Museum (Natural History). The lectures will be given under the Swiney Trust, and will be illustrated by lantern slides and the lime-light. Admission to the course is free.

Railways in Spain.—In his report on the trade of Bilbao (No. 4341, Annual Series), Mr. Consul Maclean says that a Royal Order has recently been gazetted to clear up doubts that had arisen as to the items which could be properly included under the "cost of construction," on which by the law of March 26, 1908, the Spanish Government guarantee 5 per cent. interest. This Royal Order authorises the inclusion of cost of rolling stock, surveys, plans, and accumulated interest on disbursements during period of construction—as stipulated in concession—at the rate of 5 per cent. per annum. It seems, says the Consul, to be the impression of the British Chamber of Commerce for Spain that it would be worth while for financiers and railway contractors who may be inclined to invest capital in Spain to make a careful investigation of some of the projects scheduled in the above-mentioned law. In connection with some of the projected railways it may possibly be found that local authorities, municipalities, and landowners interested would be willing to grant facilities and give valuable assistance.

FRIDAY, OCTOBER 8, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

COLONIAL SECTION.

LIST OF COMMITTEE.

Sir William H. White, K.C.B., LL.D., D.Sc., F.R.S. (Chairman of the Council).
Sir Westby B. Perceval, K.C.M.G. (Chairman of the Committee).
Earl of Aberdeen, G.C.M.G.
Hon. Sir William Arbuckle, Agent-General for Natal.
Lord Belhaven and Stenton.
Thomas Jewell Bennett, C.I.E.
Lord Blyth.
Lord Brassey, G.C.B.
Byron Brenan, C.M.G.
Richard Ernest Brounger, Agent-General for the Orange River Colony.
Sir Thomas Fowell Buxton, Bart., G.C.M.G.
Hon. Sir John A. Cockburn, K.C.M.G.
T. A. Coghlan, I.S.O., F.S.S., Agent-General for New South Wales.
Captain R. Muirhead Collins, R.N., C.M.G., Representative of the Commonwealth of Australia in London.
H. Bertram Cox, C.B.
Edward Dent.
Right Hon. Sir Charles Wentworth Dilke, Bart., M.P.
Hon. Sir Charles W. Fremantle, K.C.B.
Sir Somerset R. French, K.C.M.G., Agent-General for the Cape of Good Hope.
Right Hon. Sir George Goldie, K.C.M.G., D.C.L., LL.D.
Robert Kaye Gray.
W. L. Griffith.
Sir John J. Grinlinton.
Hon. W. Hall-Jones, High Commissioner for the Dominion of New Zealand.
Sir Charles Augustus Hartley, K.C.M.G., M.Inst.C.E.
Sir Clement Lloyd Hill, K.C.M.G., C.B., M.P.
Sir Francis J. S. Hopwood, G.C.M.G., K.C.B.
Hon. J. G. Jenkins.
Sir Alfred L. Jones, K.C.M.G.
Sir Nevile Lubbock, K.C.M.G., Chairman of the West India Committee.
Sir Charles Prestwood Lucas, K.C.M.G., C.B.
John McCall, M.D., Agent-General for Tasmania.
Sir E. Montague Nelson, K.C.M.G.
Sir Montagu F. Ommanney, G.C.M.G., K.C.B., I.S.O.
Sir Gilbert Parker, M.P.
Hon. Sir Cornthwaite Rason, Agent-General for Western Australia.
Hon. W. Pember Reeves.
Arthur H. Reid, F.R.I.B.A.
Viscount Ridley.
Right Hon. Sir Joseph West Ridgeway, G.C.B., G.C.M.G., K.C.S.I.
Alexander Siemens.
Sir John Smalman Smith, M.A.
Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C., Agent-General for the Transvaal.
Earl of Stamford.
Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., High Commissioner for the Dominion of Canada.
Sir Thomas Sutherland, G.C.M.G.
Hon. J. W. Taverner, Agent-General for Victoria.
Carmichael Thomas.
Hon. Sir Horace Tozer, K.C.M.G., Agent-General for Queensland.
Sir William Hood Treacher, K.C.M.G.
Sir Charles Rivers Wilson, G.C.M.G., C.B.
Sir John Wolfe-Barry, K.C.B., F.R.S.
Sir Frederick Young, K.C.M.G.
S. Digby, C.I.E. (Secretary of the Section).

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

STEAM TURBINES.

By Gerald Stoney,
B.E., M.Inst.C.E., M.I.E.E.

Lecture I.—Delivered March 22nd, 1909.

In considering the subject of steam turbines and their development during the last twenty-five years, it may be worth while considering the question of prime movers in general.

Man has from the earliest times sought to utilise other powers to supplement his own, and to help him in his work. In the Bible, we read in Genesis, "Jacob put his sons and wives upon camels," and the use of horses and other animals to help man by drawing loads, or carrying him, dates from the earliest times; but the use of steam in a practical form dates from about the middle of the eighteenth century. The most notable of the early engines was Newcomen's, in which steam under low pressure was admitted under a piston which rose doing little or no work, and then, when the steam was condensed by a water jet in the cylinder, the vacuum formed sucked the piston down. The top of the cylinder was generally open to the air, and water was supplied above the piston to keep it

air tight. These atmospheric engines were largely used for pumping, and the coal consumption was somewhere about 20 lbs. per horse-power hour.

James Watt, about the middle of the eighteenth century, saw that this large coal consumption was due, in a great degree, to cylinder condensation, and after trying the effect of lining the cylinders with wood to form a non-conducting lining, he hit upon the happy idea of carrying on the condensation of the steam, not in the cylinder itself, but in a separate vessel. This was, in fact, the invention of the separate condenser. At the same time, the cylinder was closed in so that there was steam, not air, above the piston. These improvements reduced the coal consumption to somewhere about $\frac{1}{4}$th to $\frac{1}{3}$rd of what it had been before, or to between 5 and 7 lbs. per horse-power hour, and at once enabled the steam engine to take its place among the great prime movers of the world.

This Watt engine remained, in principle, without improvements except in detail until the middle of the last century, when, owing to the gradual rise of steam pressure, and consequent extra expansion, compound engines began to be introduced. This was also helped at sea by the introduction of the surface condenser, without which, giving as it does fresh water to the boilers, it was impossible to use above 25 or 30 lbs. steam pressure. As engineers gradually got better materials, and more experience was gained, steam pressure increased, and the triple and finally the quadruple expansion engines were introduced with the object of increasing the expansion ratio. It has, however, been found that unless there is a steam pressure of about 7 lbs. per square inch upon the low pressure piston, the size and cost of the low pressure cylinder become excessive, and therefore the reciprocating engine is limited practically to about 16 expansions, and this is apparently about the limit of efficiency of reciprocating engines. With modern steam pressures, the consumption of coal per horse-power hour is reduced to from $1\frac{1}{2}$ lbs. to $1\frac{1}{4}$ lbs. per horse-power or some $\frac{1}{4}$th to $\frac{1}{3}$rd of that of the fuel consumed in the time of James Watt, and some $\frac{1}{15}$th of that used in the time of Newcomen.

The gain by going to higher steam pressures than the modern ones of 180 to 200 lbs. per square inch is not much, but a considerably greater gain is easily seen to be made by going to lower pressures, that is, utilising higher vacua, and this is what the steam turbine enables one to do. It therefore has always seemed to me that the greatest step in the improvement of the steam engine which has taken place since Watt's time, and Watt's invention of the separate condenser, has been the introduction of the steam turbine in a practical form.

It has been found that in the reciprocating engine there is little use, considering the temperature at which the feed water is returned to the boiler, in going to a better vacuum than 25″. With the steam turbine, vacua of $28\frac{1}{2}$″ or 29″, or absolute pressures of from $\frac{3}{4}$ to $\frac{1}{2}$ lb. per square inch, can be easily utilised, as the difficulty of dealing with large volumes of steam does not occur in the case of the steam turbine as in the case of the reciprocating engine, and it has been found that with the steam turbine the gain due to vacuum goes steadily on up to the highest attainable vacua. Between 25″ and 26″, or 26″ and 27″, there is a gain of about 4 per cent.; a further gain of 5 per cent. is made with the vacuum increased to 28″, and a still further gain of 6 to 7 per cent. when it is increased to 29″.

This is more easily understood if we consider that the theoretical power to be derived from the steam is almost proportional to the logarithm of the expansions, and thus practically the same power can be obtained working from 400 lbs. to 1 lb. absolute, or 28″ vacuum, as from 200 lb. to $\frac{1}{2}$ lb., or 29″ vacuum. In each case there are 400 expansions by pressure, and in each case the theoretical consumption of steam by Clausius' cycle would be about 9·3 lbs. per kilowatt hour. With 150°F. superheat this would come down to 8·7 lbs., and under the conditions of 200 lbs. pressure and 29″ vacuum with 150°F. superheat, 13·2 lbs. per kilowatt hour has actually been obtained with an overall efficiency, including the alternator, of about 66 per cent., or $71\frac{1}{2}$ per cent. on the turbine shaft, allowing for the electrical losses. Professor Ewing, in his book on "The Steam Engine," gives a list of principal results obtained from condensing reciprocating engines, and in no case does the ratio of the consumption of steam by Clausius' cycle, compared with that used per indicated horse-power, exceed 64 per cent. As the ratio of brake horse-power to indicated horse-power is never more than 90 per cent., this means an efficiency at the engine shaft of not more than 58 per cent. When it is remembered that the figure obtained in the case of the turbine was 71 per cent., and further that the reciprocating engine is unable to take advantage of high

vacua, it is easily seen where the advantage of the turbine, especially in large sizes, comes in.

In all machinery with reciprocating parts heavy foundations are required, and in many cases the trouble due to vibration is considerable, especially in the case of quick-running engines. As an example, in 1894 the reciprocating engines at the Manchester-Square Station of the Metropolitan Electric Supply Company caused so much annoyance on account of vibration that the Company were threatened with an injunction, and the substitution of turbines for the reciprocating engines saved the station from being shut down. Besides that, especially in large sizes, the cost of repairs and attendance is much less, while the space occupied is only about one-third or one-quarter of that required for reciprocating engines. In very large sizes it has been found practically impossible to make reciprocating engines satisfactory, and it may not, perhaps, be generally known that one of the reasons which led the Cunard Committee to adopt turbines for the great express steamers *Lusitania* and *Mauretania* was the fact that the engineering difficulties of the enormous reciprocating engines required made the problem almost impossible of solution without the use of turbines.

Steam turbines may be divided into two great divisions—single and compound. In the former class there is the De Laval, in which the whole of the expansion is carried out in a single jet impinging on a wheel rotating at a high velocity. In order to get efficiency, the highest possible velocity for the wheel has to be attained, reaching in the larger sizes some 1,200 ft. per second, above which it is practically impossible to go on account of the centrifugal forces, and this means a speed of rotation too high for the dynamo or other machine to be driven by it. The result is that gearing has to be used to reduce the speed of rotation, and this limits this class of turbine to small sizes—not, as a rule, exceeding 200 or 300 kilowatts.

The second-class is that universally adopted for all large turbines, in which the expansion of the steam is carried out in stages. If the expansion is divided up into a number of steps the velocity of the steam is greatly reduced, and thus not only can the surface velocity of the turbine wheels be reduced but also the speed of revolution, and cutting action of the steam is prevented, for high velocity steam jets are able to cut away the hardest steel. Even yet in some classes of turbines with few stages there is still cutting action on the blades.

The compound turbine naturally divides itself into two sub-classes, those in which the expansion of the steam takes place both in the fixed and moving blades, and those in which it takes place in the fixed blades only. Included in the former class is the Parsons, while the latter contains the Rateau, Zoelly, Curtis, and various others. In the Rateau and Zoelly, which strongly resemble one another, the velocity of the steam at each stage is taken up by a single row of blades mounted on a wheel, and in the Curtis by a wheel having two or more rows of moving blades with guide blades between. There are also various combinations of these, especially those with a Curtis high pressure part and a Parsons low pressure, but as yet they have not come largely into use.

And now I may perhaps be allowed to say a few words on the origin of the steam turbine on land, which dates from 1884, when Mr. Parsons made his first turbine of about 10 horse-power.

The first steam turbine Mr. Parsons made is in the South Kensington Museum, close to the Rocket and other historic engines, and Fig. 1 shows two rows of the blading of a Parsons' turbine. The steam enters the fixed blades at the top, and impinges in a series of jets on the moving blades, driving them round as shown by the arrow. Passing through the moving blades the steam issues from them in a series of jets, which by their reaction again help to drive round these moving blades. Then it passes on to the next row of fixed blades, and so on, expanding slightly at each row of blades until it finally reaches the exhaust.

Thus the old Parsons steam turbine consists of two groups of fifteen successive turbine wheels, or rows of blades, on one drum or shaft within a concentric case on the right and left of the steam inlet, the moving blades or vanes being circumferential rows projecting outwardly from the shaft and nearly touching the case, and fixed or guide blades being similarly formed and projecting inwardly from the case, nearly touching the shaft.

A series of turbine wheels on one shaft is thus constituted, each one complete in itself like a parallel flow water turbine, the steam, after performing its work in each turbine, passing on to the next, preserving its longitudinal velocity without shock, gradually falling in pressure on passing through each row of blades, and gradually expanding. Each successive row of blades is slightly larger in

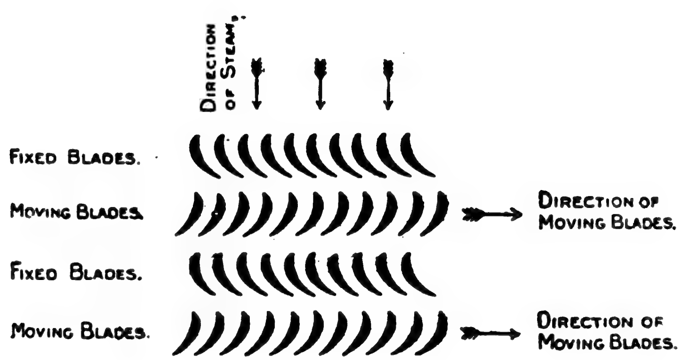
passage-way than the preceding, to allow for the increasing bulk of the elastic steam, and thus its velocity of flow is regulated so as to operate with the greatest degree of efficiency on each turbine of the series. All end pressure from the steam is balanced by the two equal series, one on each side of the inlet, and the revolving shaft lies on its bearings revolving freely without any impressed force except a steady torque urging rotation, the aggregate of the multitude of minute forces of the steam on each blade. But before this could be made a practical success it was necessary to carry out a series of experiments on shafts revolving at very high speeds, and this was done by Mr. Parsons about 1884. It is not possible to run a shaft or spindle in fixed bearings at very high speeds, as owing to the impossibility of making a shaft absolutely true, and of obtaining material of absolutely uniform density, such a shaft is always slightly out of truth and balance, and violent vibration and heating of the bearings is set up at such high speeds. This difficulty can, however, be got over by the very beautiful device of allowing a little play in the bearings to compensate for any lack of balance.

Such a bearing consists of a bush in which the spindle revolves, surrounded by three concentric tubes with a slight amount of clearance between each. The small annular spaces between the tubes are filled with a film of oil, and the whole makes a flexible bed for the shaft to run in, taking up all vibrations which in turn are damped out by the films of oil.

The steam turbine described constitutes a truly rotary engine, but it had limitations. The comparatively high speed of rotation that was necessary for so small a size of engine as this first example made it difficult to prevent a certain spring or whipping of the shaft, so that considerable clearances were found necessary, and consequently leakage and loss of efficiency resulted. It was, however, perceived that these defects would decrease as the size of the engine was increased, with a corresponding reduction of rotational velocity, and efforts were therefore made towards the construction of engines of larger size, which resulted in 1888, in several turbo-alternators of 120 horse-power being supplied for the generation of current in electric lighting stations, and in 1892, the compound steam turbine was first adapted to work in conjunction with a condenser.

The first condensing turbine was one of 150 horse-power, and at a speed of 4,800 revolutions per minute, drove an alternator of 100 kilowatts output. It was tested by Professor Ewing, and the general result of the trials was to demonstrate that the condensing steam turbine was an exceptionally economical heat engine.

FIG. 1.



With a steam pressure of 100 lbs., the steam being moderately superheated, and a vacuum of 27″ Mercury, a consumption of 27 lbs. per kilowatt hour, which is equivalent to about 16 lbs. of steam per indicated horse-power, was obtained. The result marked an era in the development of the steam turbine, and opened for it a wide field, including some of the chief applications of motive power from steam. As a result, at about this period turbine alternators of the condensing type were placed in Newcastle, Cambridge, and Scarborough Electric Supply Stations. These steam turbines were of the radial flow type, which had been reluctantly adopted in 1891 on account of the temporary loss of the patents, but on the recovery of these in 1894 the parallel flow type was reverted to with considerable improvements in design, calculated both to increase

the economy and decrease the cost of manufacture. Instead of the steam entering at the centre and expanding both ways, one set of blades was replaced by a set of dummy pistons in which a grooved piston or dummy on the spindle ran close to, but not in contact with, corresponding grooves in the cylinder, thus making a practically steam tight and yet frictionless joint. At the same time the system of blading was greatly improved, giving a more perfect form of blade with much greater mechanical strength than in the original formation.

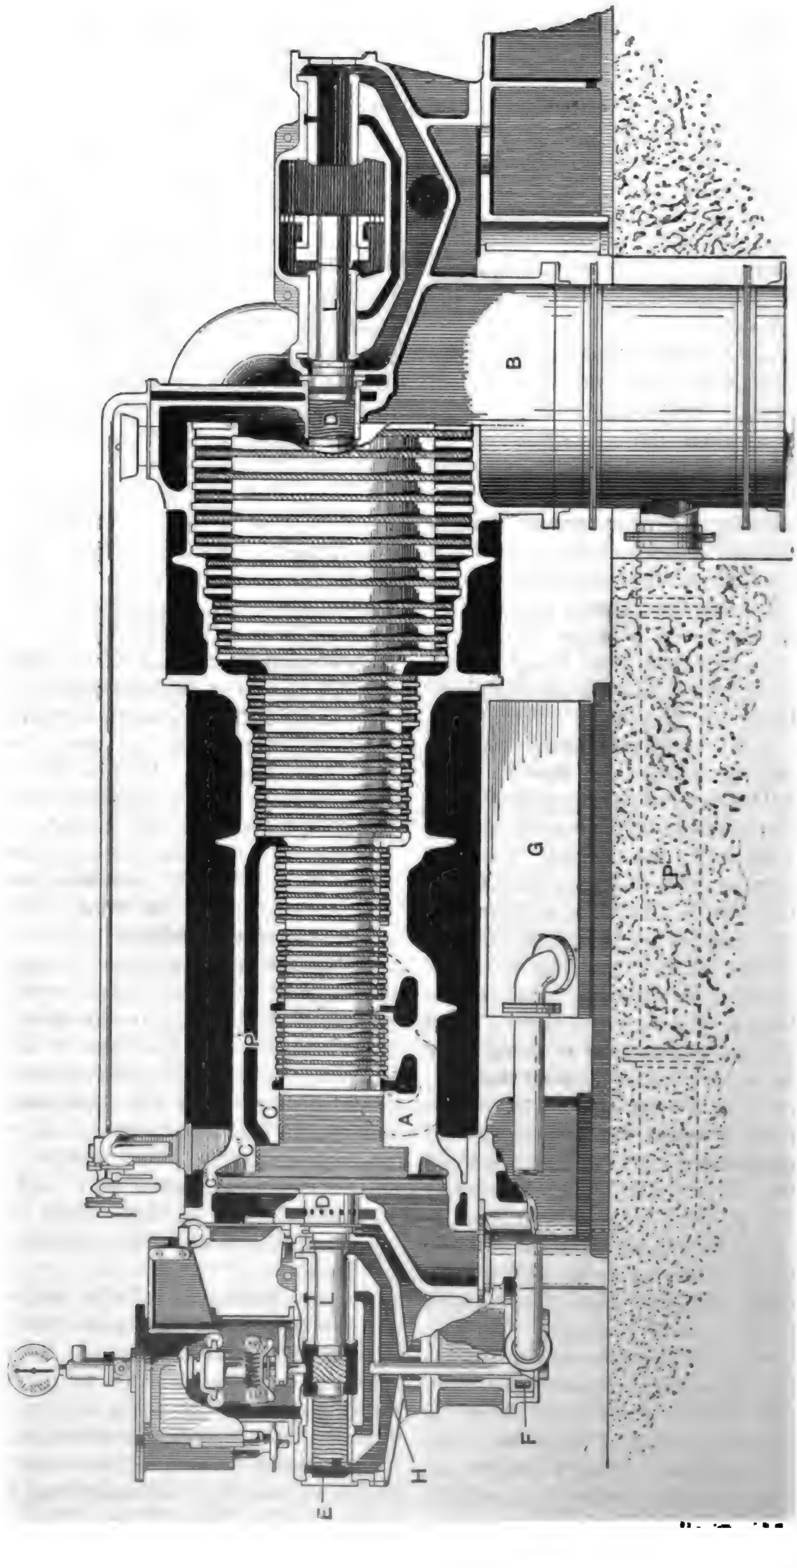
The steam turbine which is shown in section in Fig. 2 consists of a cylindrical case with rows of inwardly projecting blades. The steam enters at A on the lower half of the cylinder, thus leaving the upper half quite clear of steam pipes and all obstructions and facilitating dismantling. It then passes successively through the different rows of fixed and moving blades, as explained above, and leaves the cylinder through the exhaust pipe, B. In order to give increased passage way for the steam as it expands, the shaft is made with three steps of different diameter, the height of the blades being also increased. The steam, in addition to its rotational force, exerts a pressure endways along the shaft on the surface of the blades and the shoulders of the shaft. This is balanced by the dummy pistons, C′, C′, C‴, as shown in the section. They are made of diameter corresponding to the different parts of the turbine they balance, and are supplied with the corresponding steam pressure through the pipes, P′, P″. The shaft thus runs in complete balance endways, and can be moved backwards and forwards with a light lever, even when the turbine is running under full load. In order to prevent steam leakage, grooves are turned in these pistons, into which project, without, however, touching the moving parts, suitably shaped strips of brass caulked into grooves in the cylinder. The whole forms a labyrinthine passage offering great resistance to the escape of the steam, most of which is carried round and round by the skin friction of the dummy pistons, producing a most effective screen against leakage. The two glands, D, where the shaft leaves the turbine casing, are constructed in precisely the same manner. The steam for packing them is obtained from the exhaust of the steam relay, a live steam connection being fitted for use before starting up. An ejector is also fitted to draw excess steam away from the glands. The coupling between the turbine and generator is of the flexible claw type, to allow for slight difference in alignment of the two portions of the plant. The thrust-block, E, at the end of the turbine shaft, merely keeps it in place with the right clearance between the fixed and moving parts of the glands and dummies, and adjustment is made in a few minutes with a small liner behind the thrust-block.

The first large turbines of this improved type were of 350 kilowatts output, and were placed in the Manchester-square Station, in London, of the Metropolitan Electric Supply Company. This station was, at the time, threatened with an injunction for vibration caused by the reciprocating engines used there, and the substitution of the turbines proved entirely satisfactory, both to the users and to the Company.

In 1900, two 1,000 kilowatt turbo alternators were supplied to the City of Elberfeld in Germany, which were tested by a committee of German experts on behalf of the city, and showed a steam consumption of 18·22 lbs. per kilowatt hour at full load. This result has been surpassed in many cases, notably in the case of the 5,000 kilowatt plants for the Carville Electric Power Station, with which a consumption of 13·2 lbs. of steam per kilowatt hour was obtained. Within the last twelve years the output of the Parsons steam turbine has gone up by leaps and bounds, until there are now on land about 2,500,000 horse-power of the Parsons steam turbine at work and on order. Practically the whole of the great power distribution scheme in the North-East of England at Newcastle is supplied with these steam turbines. This not only supplies electricity for lighting to the district around Newcastle, but also the whole of the power to many works, shipyards, and factories, besides the electrification of the Tynemouth lines of the North Eastern Railway. In the power stations supplying that district there are erected—besides smaller ones—eight turbines of 5,000 kilowatts each, the latter only taking 13·2 pounds of steam per kilowatt hour at full load.

In the Rateau and Zoelly type of turbine (which have been developed chiefly on the Continent), unlike the Parsons, in which expansion takes place both in the fixed and moving blades, the whole of the expansion is in the fixed blades, the moving ones being cup-shaped so as to turn the steam and make it give up its energy without altering its velocity while passing through them. The fixed blades are in a series of diaphragms in a cylinder, with

FIG. 2.



SECTION THROUGH TURBINE.

a shaft passing through holes at their centre, which shaft carries a series of discs having cup-shaped blades on their circumference. Where the shaft passes through the diaphragms there are suitable glands so as to minimise the leakage of steam as much as possible; and, in order to get a good height of blade, the fixed or guide blades, especially at the high pressure end, only extend to a portion of the circumference. As a rule, all the discs are approximately of the same diameter, expansion of the steam being allowed for by both increasing the height of blade and also increasing the widths of the sectors of blades admitting to the revolving discs.

The Curtis turbine, which was originated in America, is of a similar construction of diaphragms, carrying sectors of fixed blades with revolving discs between, but these discs carry, instead of one row of blades, two, three, and sometimes four rows with fixed blades between, each row taking up a portion of the velocity of the steam and delivering it to the next row of guide blades at reduced velocity; and when its energy has become exhausted, it is delivered to the next diaphragm, where the drop of pressure enables it again to act on another set of moving and guide blades, and so on until the exhanst is reached.

And now as to the theoretical aspects of the question. Some sixty to seventy years ago the thermo-dynamic theory of steam was worked out by Carnot, Regnault, Clausius, Rankine, Kelvin, and others, and it was shown that under given conditions of superheat, steam pressure, and vacuum, it was not possible to get more than the amount of power out of the steam as expressed by the cycle which was worked out almost simultaneously by Rankine and Clausius. It is, then, the object of the turbine designer to obtain a result as close as possible to the result which should be obtained according to the above cycle. In this connection it is necessary to have the ratio of the steam passing through the blades the best in relation to the velocity of the blades, and experience has shown that in the Parsons type of turbine this is best when the velocity of the steam is somewhere about double the velocity of the blades, and in the Rateau a little over one-third.

Now the velocity of the steam depends on the drop in pressure between one row of blades and the next, and it can be shown that $v^2 = 2\ g\ H\ \frac{dp}{p}$ where $g =$ gravity, H is the homogeneous head of steam which is about 63,000 feet for high pressure steam and about 45,000 feet for steam at atmospheric pressure, p is the absolute pressure at any row of blades, and dp is the drop of pressure between one row of blades and the next, and therefore $\frac{dp}{p}$ is the amount of expansion that takes place in any row of blades.

Take, as an example, a Parsons turbine, as shown in Fig. 3, which is the blading diagram for a 500 kilowatts turbine for 3,000 revolutions per minute, and 150 lbs. pressure, with a vacuum of 28″. If we assume that the turbine is of the same diameter throughout, it is easily seen that since the speed of the blades is constant, in order to make the velocity ratio between the steam and the blades constant, the velocity of the steam through the blades must be constant, and as the steam at each row expands by the amount $\frac{dp}{p}$ it is evident that each row must have larger openings than the one before by the amount $\frac{dp}{p}$, and also that this ratio $\frac{dp}{p}$ is a constant throughout the turbine on the assumption that H is constant, which is approximately the case, and for a preliminary consideration may be assumed.

From the equation $v^2 = 2\ g\ H\ \frac{dp}{p}$ the velocity of the steam can be calculated at any point along the turbine, and from this and the area through the blades the quantity of steam used per hour can be calculated. In taking the area of the blades it is necessary, not only to take the actual area through the blades, but also that of the clearance space above them, and further to the quantity thus calculated there has to be added the leakage through the dummies, and also, if steam packed glands are used, the quantity of steam required to pack these glands.

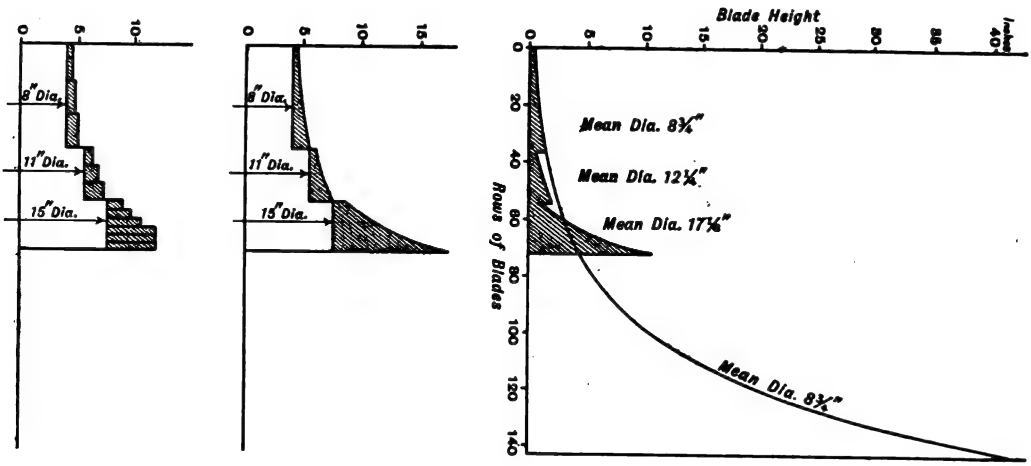
Both these items, especially the latter, are small ones, but when all these allowances are made it is found that within errors of observation the quantity of steam used by a turbine is the calculated one. It is thus easy to calculate the quantity of steam used by a turbine, but the horse-power it will produce is another question, and in many cases, especially in new types or sizes of turbine where the steam consumption per kilowatt hour was uncertain and a considerable magin was left, it was found that the steam pressures required to give the rated output were considerably lower than was anticipated.

The fact that the steam consumption of a

turbine so nearly agrees with theory proves that the velocity of steam through the blades must very closely approach the theoretical, and in fact, unless this was the case, it would be impossible to get from turbines the high efficiencies that are obtained. We therefore have a turbine consisting of a drum with blades gradually increasing in height according to what is known as a logarithmic law, that is, each row of blades is $\frac{dp}{p}$ higher than the preceding one.

Now since, in an ordinary turbine working from say 150 lbs. steam pressure down to a pressure of one pound absolute, or a vacuum of 28″, there are about 150 expansions by pressure—or, say, 100 expansions by volume—drums each $\sqrt{2}$ or 1·4 times the diameter of the other, and thus the blades on the second drum are half the height of what they would be if they had been on the diameter of the first drum, and the blades on the last drum one quarter the height of what they would have been if they had been on the diameter of the first drum. This, in the case mentioned above, where there are 100 expansions by volume, reduces the ratio of blade heights from 100 to 25, and by making the blades at the exhaust end of larger opening, so that they have double the capacity for steam of the ordinary blades, the ratio of blade heights is further reduced down to 12½, and this is a very common ratio between the blades at the high pressure and

Fig. 3.



we require the blades at the low pressure end 100 times as long as the high pressure end, so that it will easily be seen that the blades at the low pressure end would be so long as to be impossible to put on the spindle. The device, therefore is adopted of increasing the diameter towards the low pressure end (see Fig. 3), and, since an increase of diameter also increases not only the circumference but also the velocity of the blades, it is easily seen that the height of blade will vary inversely as the square of the diameter: that is, if you double the diameter, you double the velocity of the blades, therefore you double the velocity of the steam, so that you require only half the area through the blades, but since the circumference is doubled you only require blades of one quarter the height. The usual custom in land turbines is to have three the blades at the low pressure end in ordinary land turbines.

The three drums of the turbine are so proportioned that about a quarter of the power is in the first, a quarter is in the second, and half in the third, but this is purely an arbitrary division, and can be varied within wide limits to any extent desired, but in practice it comes out as a very fair compromise between the various conflicting conditions that have to be considered. Small diameters are an advantage, because you get longer blades, but, on the other hand, as we have shown before, the height of the blade varies inversely as the square of the diameter, and it must be further remembered that the number of rows required for a definite expansion also varies inversely as the square of the diameter, and therefore with small diameters you get great length of

drum and long blades, and with larger diameters you get short drums and short blades. The first gives you a turbine shaft of great length which is liable to bend and whip, and therefore the clearance over the tops of the blades has to be increased: the latter gives you very short blades, and on account of their shortness the percentage loss by leakage over the top of the blades is large, and the best result is obtained by a happy compromise between the various conflicting conditions. In this relation it is easily seen that for any given number of expansions and revolutions to obtain a given velocity ratio, a certain volume of spindle is necessary, or generally a more convenient way of expressing it is that the product of the number of rows multiplied by the square of the blade velocity gives a constant which, for any given number of expansions gives a certain velocity ratio between the blades and the steam, which may be from 0·4 to 0·6.

The above theory is on the assumption that H is constant, that is, that steam is a perfect gas, which, of course, is not quite true, and therefore, in order to attain accuracy, corrections have to be made for the difference between steam and a perfect gas, but these being of a secondary order, they are as a rule most easily made by considering H to be constant for various portions of a turbine separately.

In the above turbine, as I have shown, the theoretical curve for the blades is a logarithmic one, but it is almost impossible in practice to make a spindle and cylinder of logarithmic curves, and therefore the device is adopted of stepping the turbine, and, as shown in Figs. 2 and 3, it will be seen that the blades are stepped so as to approximate closely to a logarithmic curve, each step being made so small that there is no appreciable loss of efficiency due to the varying velocity ratios along the step. Another method of calculating turbines is by the entropy diagram or $\theta\ \varphi$ method, and this leads to exactly the same results as the method using H, or the homogeneous head of steam, which is given above. Some designers prefer one method, and some the other, but personally I have always preferred what may be called the H method.

Other types of turbines such as the Zoelly, Rateau, and Curtis, can be calculated in the same way, but the velocity ratios to give the best results are different for them, and each type of turbine has to be considered separately on its own merits. In turbines, it is easily seen that, for a given size, the lower limit of speed is one in which the blades become so short as to cause excessive leakage, and thus loss of efficiency. On the other hand, the upper limit of speed is one in which it is impossible to get sufficient area through the low pressure blades to give good results, since it is not allowable to stress the drum or disc to which the blades are fastened beyond a certain point, and therefore the surface speed is fixed, and it is also necessary not to stress the blades beyond a certain point, and therefore the maximum height of the blade on the drum or disc is also fixed.

Another thing is that it is found not to be advisable to have the height of blades more than one-fifth to one quarter of the diameter of the drum to which they are fixed, as otherwise they spread so much at the tips as to become a bad shape.

With these limitations, it can be shown that turbines can be constructed of similar dimensions to run at speeds the inverse of those dimensions. Thus, if we take a 1,000 kilowatt turbine, running at 3,000 revolutions per minute, and double the size of it all over, the surface speeds will be the same at 1,500 revolutions per minute, and the stresses on the material of the blades, drum, &c., will be the same. On the other hand, we have double the diameter and double the height of blade, and therefore four times the area for the steam to pass through, with the blades moving at the same velocity, and, as a result, four times the power will be obtained, or our turbine at 1,500 revolutions will give an output of 4,000 kilowatts. This gives the limiting speed for any given turbine, but except in exhaust turbines, which work with steam at atmospheric pressure, and therefore have to deal with great volumes, and also turbine-driven blowers which run at an average of about one and a-half times the speed of turbines driving alternators and dynamos for similar outputs, this limit is rarely attained.

Now it can be shewn that alternators also obey the same rule of varying inversely as the square of the speed, and thus it will be seen that alternators coupled to turbines go up in size together, and that apart from the trouble there is due to being compelled to have an even number of poles, alternators of the maximum size for that speed have similar turbines attached to them. For instance, as above, a 1,000 kilowatt turbine attached to a 1,000 kilowatt alternator at 3,000 revolutions per minute will have similar properties and characteristics

to that of a 4,000 kilowatt turbine attached to a 4,000 kilowatt alternator at 1,500 revolutions per minute, and thus there is no limit to the size of turbo-alternator. In the case, however, of continuous current dynamos, the output of a dynamo (as it is chiefly limited by commutation conditions which depend principally on the ampere turns on the armature per inch diameter) is practically only proportional to the speed, and it is easily seen that a limit is soon reached where the speed of the turbine is too low for economical conditions.

This statement that the output of a dynamo varies inversely as the speed is not exactly true, the real ratio in practice being as the 1½ power of the speed, but still soon a limit is reached for continuous current work, and although we can make a 1,000 kilowatt alternator running at 3,000 revolutions per minute we can only make a 500 kilowatt continuous current dynamo to run at the same speed, or a 1,200 kilowatt to run at 1,500 revolutions per minute. The 500 kilowatts at 3,000 revolutions per minute is a very good machine, and so is the latter, but this is about the lowest speed at which a turbine can economically run at that size, and thus no-one has put more than about 1,200 or 1,500 kilowatts into one dynamo. However, by using tandem dynamos it will be seen that the output is doubled, and this enables tandem turbo-dynamos up to about 4,000 kilowatts to be economically built.

In the design of marine turbines the same lines are followed exactly as in the design of land turbines, but in marine turbines the limitations of the screw propeller are to be dealt with instead of the limitations of dynamos, alternators, &c., in land work, and the importance of carefully balancing the efficiency of the propeller against the efficiency of the turbine has to be most fully considered. Screw propellers, as a rule, are more efficient the slower they go, turbines are less efficient the slower they go, and therefore the balance between the two has to be most carfully looked into. As a result it has been found that with simple installations of screw propellers and turbines it is not advisable to go in speed below 15 to 18 knots. This will be easily understood if we take, for example, the express Cunarders *Lusitania* and *Mauretania*, and compare them with the *Carmania*. The engines of both run about the same speed, viz., about 180 revolutions per minute, and yet for 25 knots in the *Mauretania* there is a power of about 65,000 horse-power, and for 18 knots in the *Carmania* there is only about 20,000 horse-power. It is thus seen that, on account of the limitations of the screw propellers, while the turbines on the *Lusitania* and *Mauretania* are working under the best conditions possible, the turbines of the *Carmania* are not working under nearly so good conditions, and it was only on account of her very careful designing that the *Carmania* has proved to be the success she is.

This subject will be further dealt with in my last lecture.

HOME INDUSTRIES.

Unemployment.—The question of unemployment is becoming acute again. The state of the labour market is serious and the outlook discouraging. During the first five days in which the Registers of the Metropolitan Distress Committee were opened the number of applicants was 7,800, a higher total than for the corresponding period of last year. It must be remembered that the habit of applying for assistance strengthens with each year's distribution of relief work. A man who applied last year is more likely to apply this than if he had never applied; but with due allowance made for this fact the applications have increased. At the first meeting of the Central (Unemployed) Body for London, held last week, a resolution was unanimously passed declaring that "in the experience of the Central Body the Unemployed Workmen's Act of 1905 has proved quite inadequate to deal with the constantly recurring distress from unemployment." But it is fair to the authors of that Act to remember that it was passed as an experiment for three years only. The main object of the Act was the direct assistance of the unemployed by the old method of temporary relief work. It aimed at providing a temporary refuge for a comparatively few men, and it was not intended that it should be used by men not competent and industrious. Temporary assistance by relief work was to be provided only in times of exceptional trade depression. The administration of the Act on this side was made dependent upon the raising of voluntary subscriptions. During the first year the Act was financed in this way. A public appeal on behalf of the unemployed made by the Queen resulted in the subscription of over £150,000, of which nearly £125,000 was distributed to the authorities established under the Unemployed Workmen's Act. But an appeal of this kind could not be repeated, and in 1906 Parliament put £200,000 at the disposal of the Local Government Board to supplement voluntary contributions, and this precedent was followed in 1907 and 1908. It may be doubted whether the class of persons relieved under the Act was the one intended, namely, men honestly desirous of obtaining work, but temporarily unable to do so from exceptional causes. The bulk of those relieved have been labourers or irregular workmen, with whom want of employment was not exceptional. The temporary

assistance under the Act was to be made unattractive by the rule that the "total remuneration . . . . . for any given period of continuous work should be less than that which would under ordinary circumstances be earned by an unskilled labourer for continuous work;" but the Poor-law principle, that assistance should be less attractive than independence, has not been observed. The difficulties experienced in the working of the Act throw doubts upon the practicability under present conditions of any form of public assistance outside the Poor-law. The Unemployed Workmen's Act, to quote Mr. Beveridge's review of it ("Unemployment," page 191) has done a good deal in the way of collecting information. It has done a little to co-ordinate existing agencies, and improve in minor points the administration of special relief. It has not made any appreciable impression upon the problem. Its main service has been to demonstrate the inadequacy of all measures which, like itself, leave industrial disorganisation untouched, and deal only with the resultant human suffering.

The Government and Wireless Telegraphy.—The official announcement of an agreement between the Post Office and the Marconi Company by which the former acquires for £15,000 all the Marconi coast stations communicating with ships, the surrender of all rights held under agreement with the Post Office, and liberty to use free of royalties all existing and future Marconi patents for the next 14 years for ship to shore communications, has been received with much satisfaction. From the strategic as from the commercial point of view the arrangement is of obvious value. In making his statement to the House of Commons the Postmaster-General said that the negotiations and arrangements have been conducted with the knowledge of, and in consultation with the Admiralty, who have long desired that the coast wireless stations should be in the hands of the Post Office. And from the commercial standpoint the arrangement is welcomed. It is in no sense an exclusive one. All the stations will, under the International Radio-Telegraphic Convention, be open for communication equally to all ships whatever system of wireless telegraphy they may carry, and the Post Office will be free to use or experiment with any system of wireless telegraphy that may commend itself. The Postmaster-General was able to add that arrangements have also been made with Lloyds for the transfer to the Post Office of their wireless stations for communications with ships, and for the surrender of all claims to licenses for such communication. In return Lloyds will receive the plant value of their stations, and will have transmitted to them (with due regard to the secrecy of private telegrams) information received at the Post Office stations with regard to the position and movement of ships, and other maritime intelligence. The agreement by which Lloyds bound themselves to use only the Marconi system—an agreement always regretted by Lloyds—is cancelled, and the net result of these arrangements is that the State acquires all the wireless stations engaged in commercial work in this country, except the long distance stations, and the possibility of a private company and a single system securing a monopoly is disposed of. That these many advantages should have been secured by the Government for £15,000 is remarkable.

Shipbuilding.—The high price, comparatively, of steel, and the speculative position of pig iron, make shipbuilders a little shy of booking new orders on the basis of the present prices of material, while shipowners are not likely to buy more new ships if prices are advanced. But the record of the Scotch shipbuilding yards for September shows improvement upon that of the preceding month, the output being about 2,500 tons more than for August. The Clyde production of September was about 46,000 tons, a large part of it—32,000 tons—being of the tramp order. A large proportion of the new work is on war ships. There are now building on the Clyde one battleship, two cruisers, and twenty torpedo boat destroyers, in addition to a cruiser just launched. The new contracts of September are estimated at about 45,000 tons, and it is understood that more contracts have been booked than have been reported. Many of the Clyde shipbuilders are said to have work in hand that will keep them well employed on to the spring.

Asylum Workers' Pensions.—Sir William Collins' Asylum Workers Superannuation Bill has now reached the Lords, and as in 1898 they passed through all its stages a Bill granting pensions to all asylum workers without the contributory basis—which is the basis of the present Bill—it may be assumed that the Peers will agree to it. Sir William Collins' Bill gives assured pensions to workers in asylums, whereas the present law only gives optional power to the authorities to grant such pensions under the Act of 1890. The Home Office and the Lunacy Commissioners are in favour of the Bill, and it is well backed throughout the kingdom.

Sea Fisheries.—A conference has been arranged by the National Sea Fisheries Protection Association to be held at the Town Hall, Great Yarmouth, on the 19th and 20th of this month. The list of subjects to be discussed is a large one, and includes "Fish diet for the Navy and Army," "Rewards for evidence to convict trawlers," and "The compulsory granting of certificates to captains of steam fishing-vessels."

Lighting-up Factories.—A safe method of lighting-up in factories and other industrial premises where gas is used has long been wanted. Electric torches are used, but it is found to be difficult to keep them in perfect working order at all times. The safety lamp invented by Messrs. Hall and Kay is used largely in cotton mills, but there is a difficulty with incandescent gas where the burners are of the inverted

type, and the mantles enclosed in globes. A new torch has just been put upon the market which is said to prove equally effective with all kinds of burners. It consists of a slender metal cylinder containing a lamp, burning colza oil. Pressing a button raises the lamp within the cylinder until the flame is projected against a protecting shield constructed of wire mesh over the top of the cylinder. Three small arms tipped with rubber, and projecting laterally from the top of the cylinder, protect the incandescent mantle from injury through impact of the torch against any part of the gas fittings.

CORRESPONDENCE.

BURIED TOADS.

In confirmation of Sir James Monteath's story, I send you the following account of a toad which was discovered in a plum tree when it was cut down. It was in Jersey in 1856. The creature looked dead; the tree had grown round it and shewed no sign of crevice, or rent. It was not a large tree but very picturesque in contortion of branches, and had left off bearing fruit and gradually withered. The old gardener decided to cut it down and plant a new one. When he began to cut the trunk into sections he discovered the toad and split the tree in two to liberate it. The wood was simple rotten fibre, very white, and had evidently grown round the live creature, for when it came out of its hole, a perfect mould was left of it, even the strange flat feet defined as if it had been a plaster of Paris mould. Of course we thought it was dead and so buried it, but for fear it should come to life again poured boiling water on it. After about half-an-hour it showed signs of life. In about three days it began to swell out and get moist and hide under the big leaves in the garden; in a month it was difficult to distinguish it from other toads, and it was very lively. After six months we left the place, and I do not know how long it lived. The piece of tree was given to the museum by Col. Turner, who said he thought the tree was about 30 years old, and the toad must have been in it some 25 years, a mere minute compared with his Indian brethren.

M. ADLINGTON.

[Toads about to hibernate crawl into holes, and this fact is believed to account for the numerous stories of their being found embedded in rock or in tree trunks. There is no doubt that a frog or a toad can live for a considerable time—several months —with little or no food, so long as he is kept damp. Put him in a dry place and he shrivels up at once. The reason for this is that his skin is richly provided with blood vessels, and acts as an efficient respiratory organ; but the exchange of gases, which is the essential part of respiration, cannot be carried on save with a moist membrane. A frog in an ordinary sitting-room would die in a few hours of asphyxia. Frank Buckland, in his "Curiosities of Natural History" (published in 1857), records some experiments made by his father, Dean Buckland, to test the possibility of toads living enclosed in cavities. From these experiments it appears that toads, sealed up in small chambers of porous stone, to which air and water could percolate, and to which possibly small insects might have had access, in a few cases survived as long as two years. Toads placed in holes in trees with the openings plugged up were all found to be dead and decayed at the end of a year. Dr. Buckland was never able to find trustworthy evidence for any of the numerous stories of toads having been found in cavities of rocks or trees where they had been entombed for any great length of time. His record story was one of a frog disinterred from a block of coal freshly hewn in a coal mine. The newspaper reporter comments on the animal having been a contemporary of Noah, or even of Adam, but here he would seem to have done scant justice to the longevity of his frog, since neither of these patriarchs can conceivably have lived in the carboniferous epoch.—ED.]

OBITUARY.

SIR JOHN HENRY JOHNSON.—Sir John Henry Johnson, who died at his house near Clacton-on-Sea on the 2nd inst., was a life member of the Society since 1890. He was for many years an active member of the Court of the Drapers' Company, and was one of those who were associated with the movement which resulted in the establishment of the City and Guilds of London Institute. When the Drapers' Company dissociated themselves from the Institute, and devoted their funds, and their attention, to the development of the East London College at the People's Palace in Mile-end-road, Sir John Johnson took a great deal of interest in the work, and became Chairman and Treasurer of the College. He was twice Master of the Drapers' Company.

THEODORE MINOT CLARK.—An intimation has been received of the death at Boston, on April 30th, of Mr. Theodore Minot Clark. Mr. Clark was born in Boston in 1845, and educated at Harvard, whence he graduated in 1866. Having selected architecture as his profession, he came into prominence by his plans for a series of great docks in South Boston, and he was also the prime mover in the establishment of a day camp for consumptives on Parker Hill, the buildings of which were designed by him. He was the author of many well-known books on architectural subjects, notable among which are "Rural School Architecture," "Care of a House," and "Building Superintendence." He joined the Royal Society of Arts in 1903; he was also a Fellow of the American Institute of Architects and a member of the International Institute of Public Art at Brussels.

NOTICES.

VIVA VOCE EXAMINATIONS IN MODERN LANGUAGES.

During the present year 27 examinations have been held in London, Manchester, Bristol, Hitchin and Guernsey.

At these examinations 656 candidates presented themselves, of whom 506 passed (166 with distinction) and 150 failed. The languages taken up were French, German, Spanish and Italian.

The results of previous years are as follows:—

Year.	Number Examined.	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175
1907	629	476	153
1908	615	467	148

The following is a complete list of the *Vivâ Voce* Examinations held during 1909:—

Place of Examination.	Date.	Number of Candidates.	Passed with Distinction.	Passed.	Failed.
French:—					
Hitchin	March 22.	20	1	11	8
Regent-street Polytechnic (Candidates from London Polytechnics)	May 18.	24	4	15	5

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

STEAM TURBINES.

By Gerald Stoney,
B.E., M.Inst.C.E., M.I.E.E.

Lecture II.—Delivered March 29th, 1909.

In my last lecture a short account of steam turbines in general was given; in this one are described various applications of the steam turbine and some things which have conduced to its efficiency.

The design of condensers has been especially influenced by the introduction of steam turbines. As has been shown, in the old days of reciprocating engines, the condenser giving 25″ vacuum was quite good enough, but now-a-days, on account of the great improvement in economy of steam turbines, with higher vacua, it is common to have between 28″ and 29″. As a rule in the case of a condensing plant the temperature of the cooling water is fixed, and therefore, in order to obtain as low a temperature of the outlet water from the condenser as possible as large a quantity of cooling water as is practicable should be used. This again is limited by the power required to pump the water, and also by other considerations, especially where cooling towers are used, but as a fair average it is generally found that somewhere between 50 and 70 times the steam condensed can be obtained. This means a rise in temperature of the cooling water of about 17° Fahr., as it takes on an average about 1,000 B.T.U. to condense one pound of steam. This figure is rather lower than the one for dry steam, but it must be remembered that exhaust steam is nearly always wet, and therefore takes rather less B.T.U., and we have found in practice that 1,000 B.T.U. per pound of steam is a very fair figure to take.

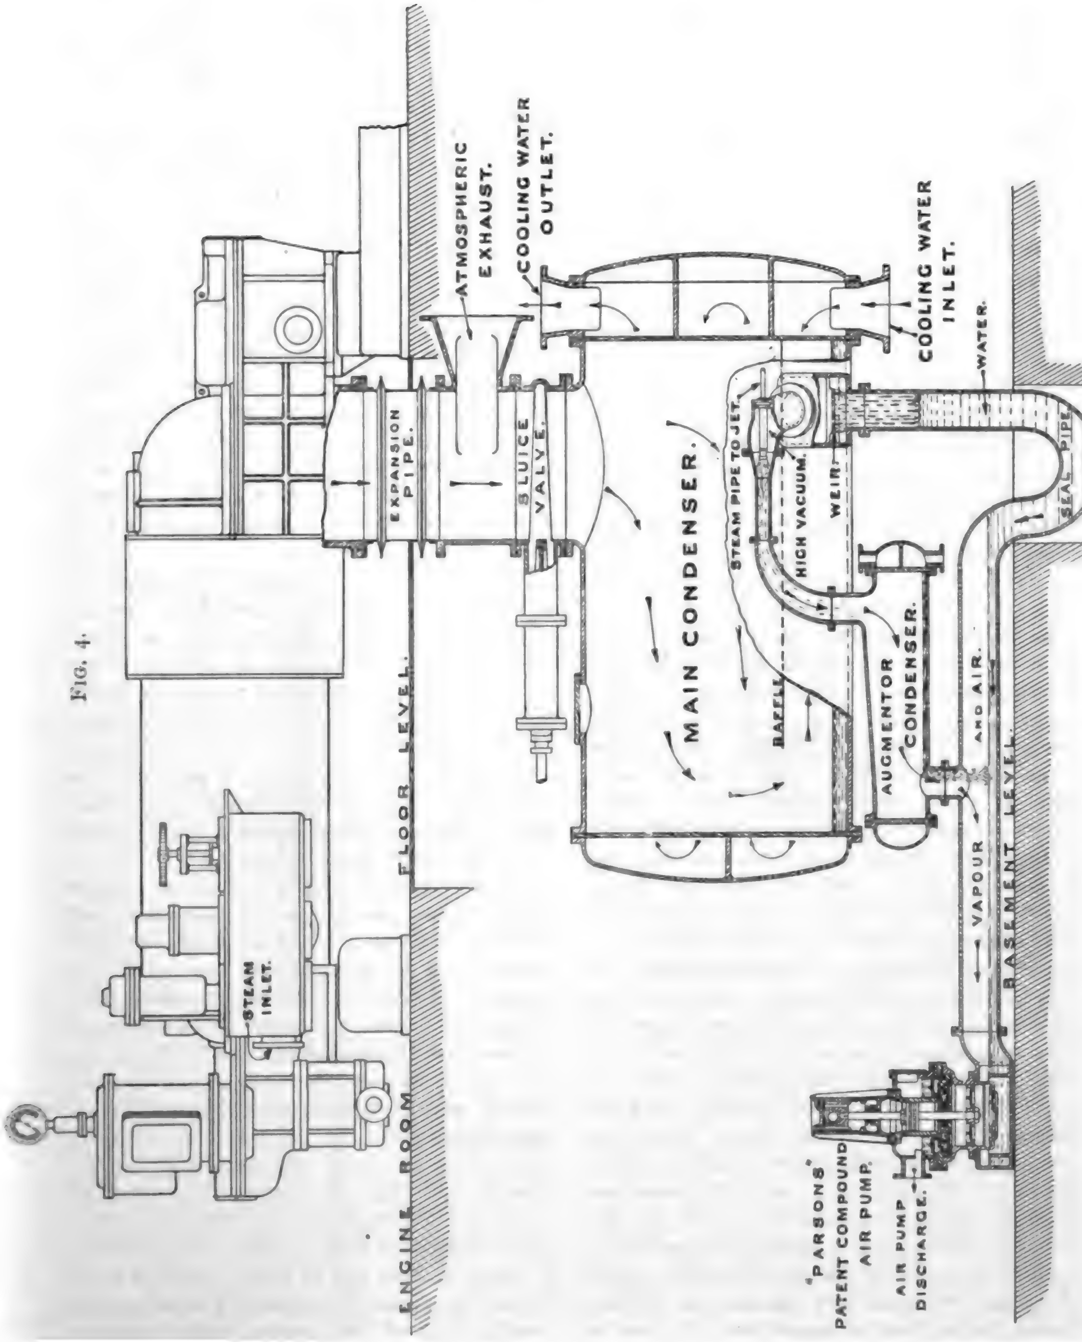
The maximum vacuum which can be obtained from a condenser is the vacuum due to the temperature of the outlet water, and the closer to this we can get the vacuum actually obtained the better. There are two ways of expressing this difference: one is in inches of mercury, and the other is in temperature, and for condenser work the latter is the more convenient. When it is remembered that from about 24″ to 27″, each inch of vacuum makes 4 per cent. difference in the steam consumption of a turbine, between 27″ and 28″ about 5 per cent., and from 28″ to 29″ six or seven per cent., or that approximately 3° Fahr. difference in the temperature of the exhaust, means an increase or decrease of about 1 per cent., it is easily understood how important it is to keep the difference of temperature between the outlet water from the condenser, and the temperature due to the vacuum as small as possible. This difference in good modern condensers, when condensing, say 12 lbs. per square foot per hour, can be kept as low as 5° or 6° Fahr.

Another way of looking at the efficiency of the condenser is the B.T.U. transmitted per square foot of cooling surface per hour per 1° Fahr. difference of temperature, and this figure can in well constructed condensers be as high as 1,000 to 1,200 B.T.U. The resistance to the heat passing from the steam to the water may be considered in three stages. There is first the heat transmitted from the steam to the tubes of the condenser, and this resistance is affected by the quantity of air in the condenser, and the efficiency of the air pump. With suitable arrangements, however, this resistance can be reduced to a very small figure, especially if appliances are used such as dry air pumps, or, still better, Mr. Parsons' vacuum augmentor, to withdraw the air completely from the condenser. If air is present it not only vitiates the vacuum, but also reduces the rate of condensation of the steam by, so to speak, causing a blanket of air to form round the tubes, and thus preventing fresh steam getting to them. The second resistance to the transmission of heat is in the metal of the tube itself, but this, with metal tubes, such as are always used, is an exceedingly small figure, and may be neglected. The third and last is the resistance to the passage of heat between the metal of the tubes and the cooling water, and this is apparently one of the principal losses, and varies enormously with the cleanliness of the tube. If there is any slime or dirt or deposit on the inside of the tube it is found that conduction of heat very rapidly goes down, and therefore to get the best results the tubes must be kept clean. In this connection also it is necessary to have sufficient velocity of flow of the water to make turbulent flow in the tubes and not stream line flow, that is, a velocity sufficient to make the water mix up as it is travelling along the tubes and not to have a cold core of water with a hot envelope outside it next the tubes.

It is in connection with the extracting of air thoroughly from the condenser that the greatest

improvements have been made of late years, and amongst these dry air pumps, and the vacuum augmentor mentioned above and denser to the air pump, and thus, although the air pump may only produce a vacuum of, say, 27″ or 28″ there may be a vacuum of 28″ to

Fig. 4.



Diagrammatic Arrangement of Vacuum Augmentor.

shown in Fig. 4, are especially prominent. This latter consists simply of a jet of steam drawing the air and vapour from the condenser and delivering it through a small auxiliary condenser to the air pump ... 29″ in the condenser, and in practice this appliance has been found most satisfactory. The effect of using this vacuum augmentor has been in some cases to bring up the conductivity

from about 250 or 300 to between 800 and 1,000, or to reduce the loss of temperature from some 26° Fahr. to 5° Fahr., a gain in temperature of, say, 21° Fahr., or 7 per cent. in the consumption of the turbine.

When it is remembered that the steam jet of the vacuum augmentor only uses about 0·6 per cent. of the steam used by the turbine it is easily seen that the gain due to the better vacuum is vastly more than the loss due to the steam jet. This vacuum augmentor is applicable not only to surface condensers, but also to jet condensers with most beneficial results.

One great field for turbines which has only within the last couple of years come into prominence, although it was patented by Mr. Parsons some years ago, is the use of exhaust turbines, that is, turbines taking steam at atmospheric pressure from reciprocating engines or other machinery, and utilising the power contained in it in an exhaust turbine. When it is remembered that there is as much power in steam working from atmospheric pressure down to a 27″ vacuum, as between 150 lbs. down to atmospheric pressure, it is easily seen that the power of an existing non-condensing plant can be more than doubled by the simple application of an exhaust steam turbine and condenser. In cases where cooling water is not available, cooling towers can be fitted, and, of late years, these have been improved so much as to be most efficient pieces of apparatus. Also, in some cases, a further advantage has been obtained in that if the supply of water for feeding the boilers is bad, this bad water can be used in the cooling towers, where it does no harm, and pure condensed water from the turbines can be supplied to the boilers. Such installations are now in use all over the country, and from being absolutely a waste product, exhaust steam has become a most valuable by-product in many works, the exhaust steam being collected, made to drive turbines and dynamos, and the power either used in the works where the exhaust steam is produced or supplied to other consumers of electricity. In many cases the exhaust steam is intermittent, such as the exhaust steam from a winding engine of a colliery where each time the cage goes up or down there is steam from the winding engine, but in the intervals between the winds, there is none. Such intervals, if not too long, can be bridged over by a thermal accumulator. The principle of thermal storage is itself a comparatively old idea in connection with steam boilers, having been proposed by Druitt Halpin in 1891-92, but the best known form of accumulator for use in connection with exhaust steam turbines is that of Professor Rateau, where a tank containing water has the exhaust steam blown through it so that alternately the exhaust steam is partly condensed, and the water in the tank boils, and thus the supply given to the turbine is constant.

In many cases, however, the stops are too long to be bridged over by any form of thermal accumulator, and in such cases what are called "mixed pressure" turbines have been introduced in which there is a high pressure part revolving idly when exhaust steam is used, but when the exhaust steam supply fails, by an automatic arrangement this high pressure part is supplied with live steam, and thus the turbine continues to be driven. This, also, can be used in conjunction with a thermal accumulator, in such cases as a winding engine, where there are short stops only for a portion of the day, but where there are long stops at week-ends or at times when winding is not going on.

This arrangement of turbine to be able to utilize economically either exhaust steam or high pressure steam has probably a great future before it, and it is one of the remarkable things about a turbine that it has so much flexibility that such an arrangement is possible —in fact, it has been found that such mixed pressure turbines are within 5 per cent. as economical as either a pure turbine for using high pressure steam alone or a pure turbine for using exhaust steam alone.

The first applications of the steam turbine to driving machinery were in the driving of electrical machinery, and on land this still continues to be the greatest use for steam turbines. Twenty-five years ago, when Mr. Parsons made his first high speed dynamo, the usual speed of revolution was for dynamos, as a rule, from 1,000 to 1,500 revolutions per minute, and they were generally belt-driven from the engine.

Mr. Parsons made his first high speed dynamo (see Fig. 5) to run at a speed of 18,000 revolutions per minute, and it was for a power of about 10 horse-power. This increase of speed to from ten to fifteen times that of ordinary dynamos necessitated a most careful consideration of the design, both from the electrical point of view and also to meet the enormous centrifugal forces which would be engendered. These latter were met by a drum armature with spiral end winding, the whole held together by binding wire, and

the construction of the commutator segments in short lengths, dovetailed into steel rings with asbestos insulation. The diameter also was kept small, and the core and commutator were relatively of considerable length. In all turbo-dynamos the core lengths are large and the diameter comparatively small, in order to prevent stresses due to the centrifugal force being excessive.

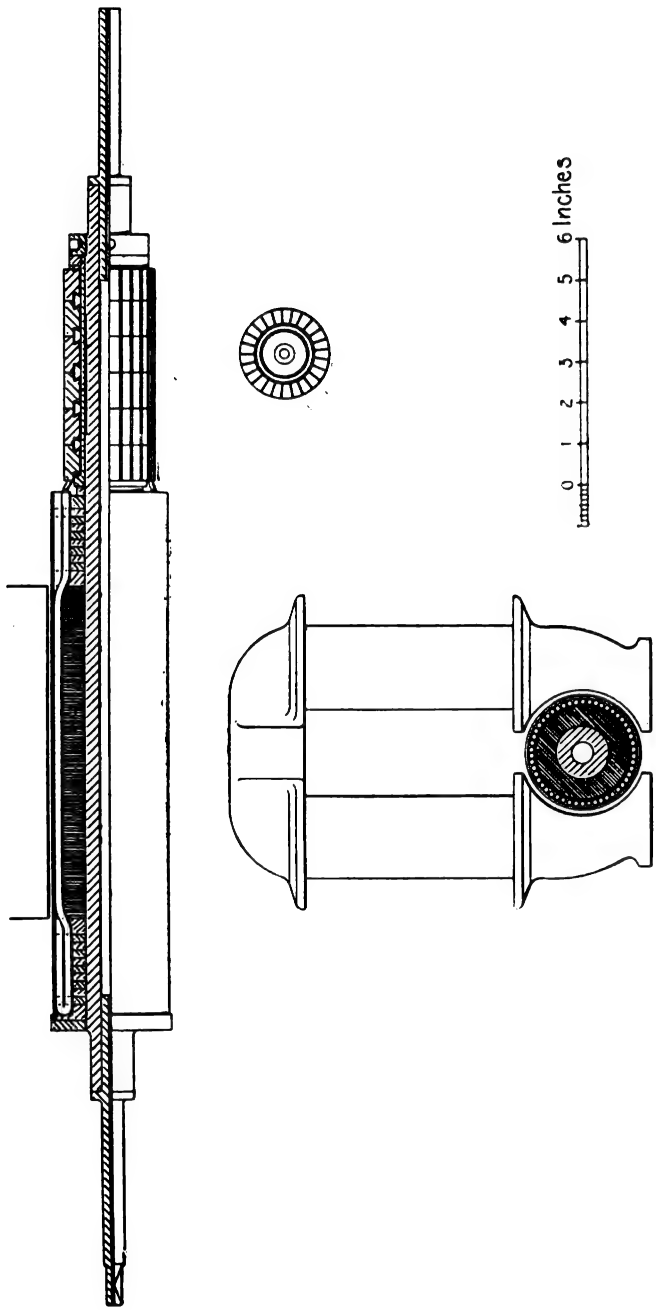


FIG. 5.

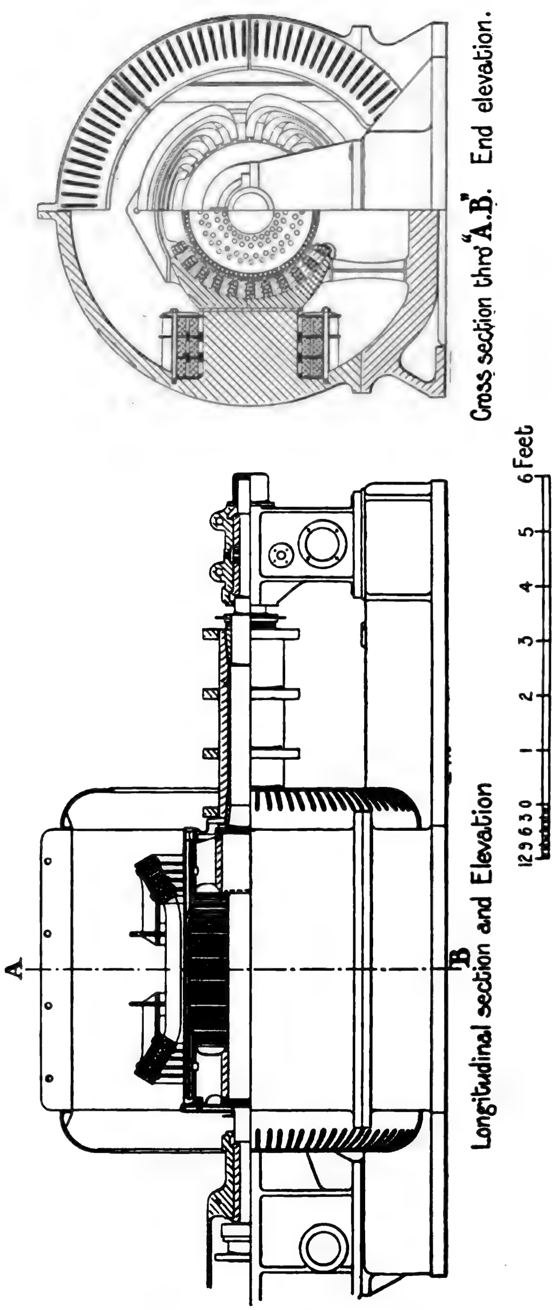
OLD TYPE CONTINUOUS-CURRENT ARMATURE.

Some of the difficulties to be met with in turbo dynamos will be understood if we compare a slow speed two-pole dynamo of 50 kilowatts for 300 revolutions per minute, with a turbo dynamo of 500 kilowatts, at 3,000 revo-

lutions per minute, also two-pole. Here we have ten times the speed of revolution, ten times the surface speed, and 100 times the centrifugal force to contend with. The output in kilowatts is proportional to the speed, or ten times, but as the former was for 110 volts, and the latter for 550, we had to have only half the number of segments, so that the voltage per segment is ten times. The frequency of the commutation is five times as great therefore, and the re-actance voltage on which the sparking largely depends is fifty times as great; and finally the hysteresis and eddy loss in the armature core will be somewhere about sixteen times as much.

FIG. 6.

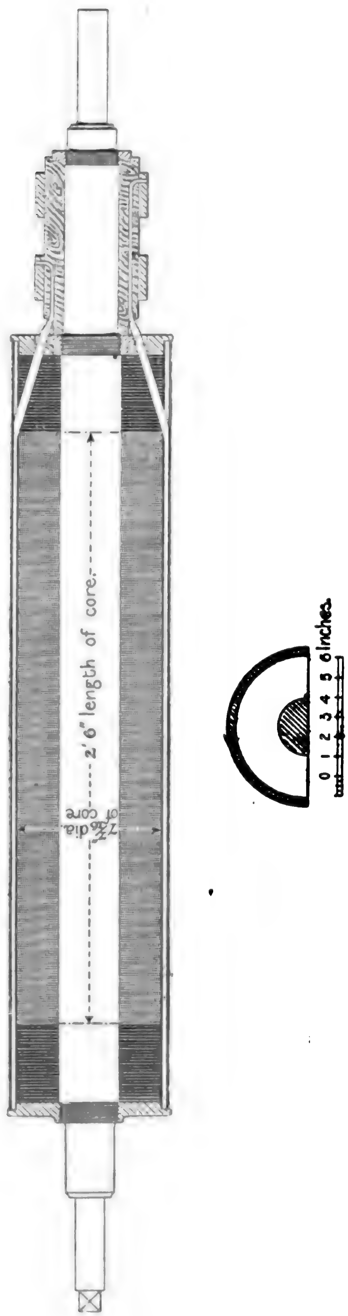


0-K.W. TURBO-GENERATOR, 480 TO 560 VOLTS, 1,800 REVS.

It is thus seen that special arrangements

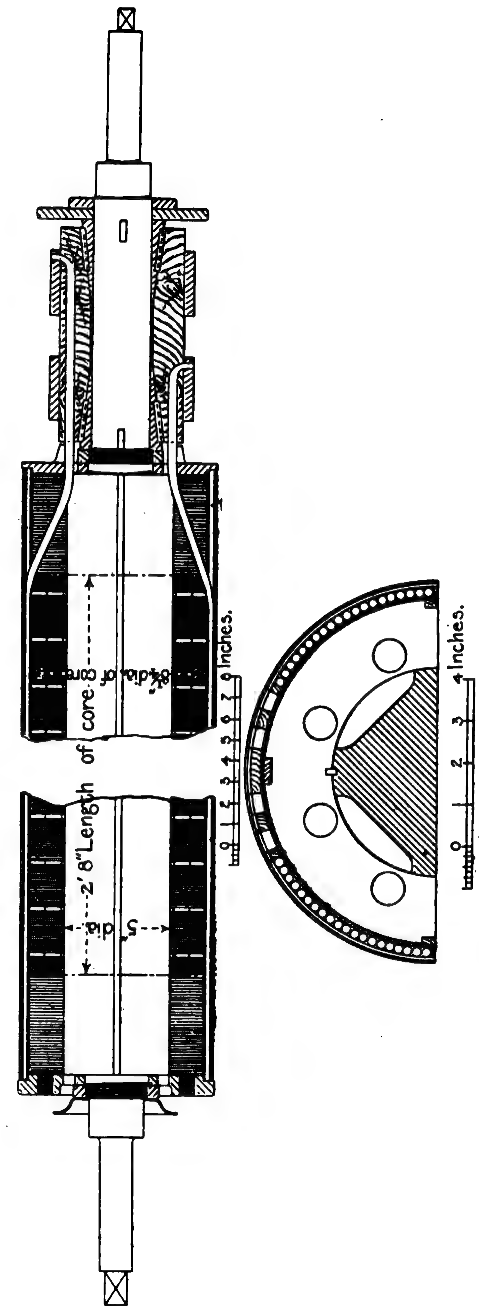
will have to be made to meet the very special conditions of a turbo dynamo. The core loss has to be taken care of by very special ventilating arrangements to enable the heat to be carried off; and centrifugal force is met by employing the best materials and most careful construction. The voltage per segment in the commutator and the re-actance voltage, the two principal things which govern commutation, are met with by the provision of either commutating poles or compensating winding, or a combination of the two. In our experience we have found compensating winding alone most satisfactory, and the adoption of such

Fig. 7.



75-K.W Single-phase Turbo-Alternator Armature.

Fig. 8.

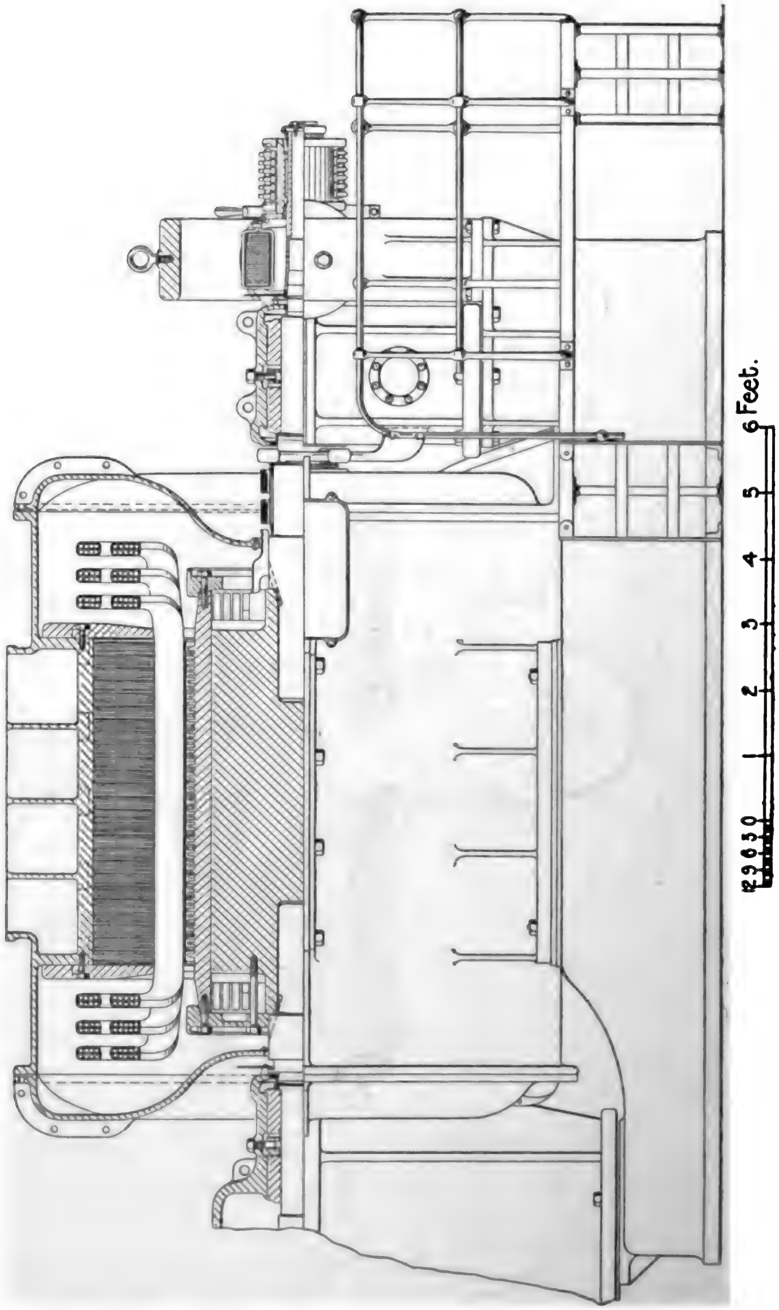


150-K.W. Single-phase Turbo-Alternator Armature, showing Air-cooling Ducts.

compensating winding enabled a dynamo with such winding to be increased in output from about 200 kilowatts to 500 kilowatts, and that 50 per cent. without sparking of the brushes, or having to shift them in any way.

I may further say that we have found in our

Fig. 9.



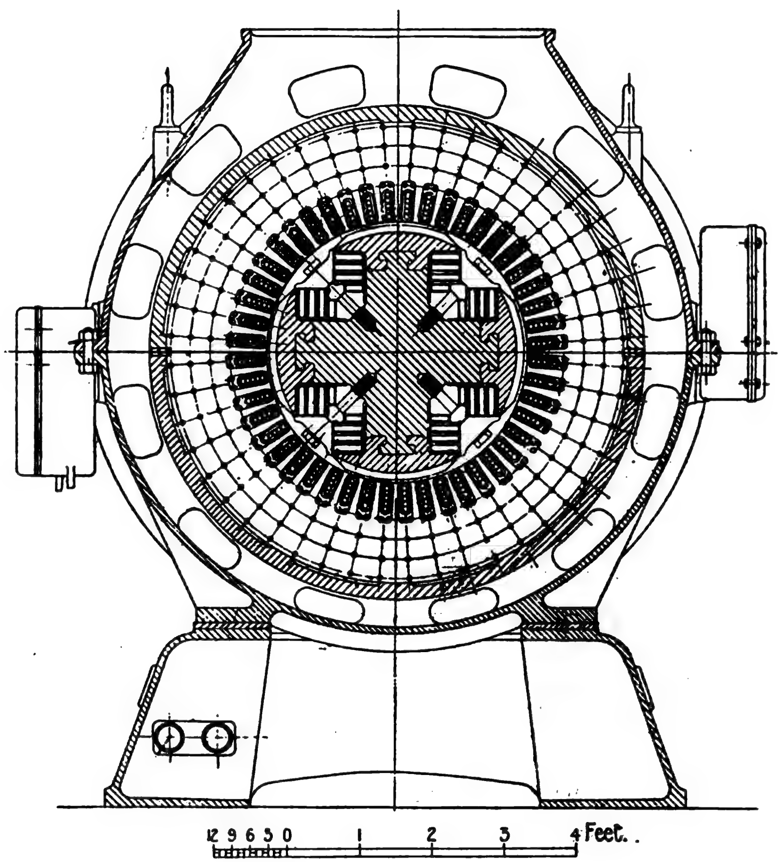
4,000-K.W. 3-Phase Turbo-Alternator with Exciter 6,000 volts.

without any shifting of the brushes such as was formerly necessary. Fig. 6 shows a 750 kilowatt turbo-generator built on the lines described above, and this can carry overloads of experience, two-pole turbo dynamos to be much more satisfactory than four-pole, and to cost little more to build, the two-pole proving to be much less liable to flash over than the

four-pole; in fact with our modern two-pole turbo dynamos such a thing as flashing over is unknown.

Turbo alternators were started rather later than turbo dynamos, the first being made about 20 years ago for the Newcastle and District Electric Lighting Company, Limited, four sets being installed in their Forth Banks station. These early alternators consisted of a smooth core having the windings laid over it and held on by binding wire, the ends being connected to slip rings, and were as a rule single phase. The size gradually increased up to 1,000 kilowatt single phase, and a voltage of 4,000 volts. Two of these early machines are shown in Figs. 7 and 8. It was found, however, that with high voltages, and especially when two or three phase alternators had to be built, the difficulties of manufacture and of insulation were very great, and therefore the type with revolving field magnets was adopted. Figs. 9 and 10 shows a 4,000 kilowatt three-phase turbo alternator for 6,000 volts., 40 periods, running at 1,200 revolutions per minute, and I may say that eight of these are installed in the Carville Power Station of Newcastle-upon-Tyne Electric Supply Company, Limited, in connection with the great power distribution in the North of England. The stator is of the usual type of laminated iron, the only noticeable point being that the end windings have to be very firmly stayed to stand up against the very heavy stresses which are occasioned if there is a short circuit or other sudden rush of current. The rotor consists of a steel casting with forged steel pole tips, the coils being separately wound and slipped on in place, after which the pole tips are put on and strong nickel steel bolts with manganese bronze keeps are used to counteract the tangential component of the centrifugal force. This rotor may be said to be typical of what is called the

FIG. 10.



4,000-K.W. 3-PHASE TURBO-ALTERNATOR, 6,000 VOLTS. (Cross Section.)

"salient pole formation," but there is also what may be called the "barrel" or "drum" type, which was first introduced by Mr. C. E. L. Brown, of Baden, Switzerland, in which the rotor consists of a series of plates with the winding embedded in slots in the outer circumference. It is a moot point which form is best, some having advantages in one way and some in the other, and which will eventually survive depends both on ease and cost of manufacture as well as mechanical and electrical advantages, and up to the present this point has not been settled. As in the case of continuous current machinery, one object is to get the maximum output at the highest speed possible, and since the materials available limit the length and diameter of rotor and therefore the available flux and the ampere turns, these again limit in the stator the output which can be obtained with a certain inherent regulation.

ordinary steam turbine when driven backwards does not act as an air compressor, but if the blades are suitably shaped it forms a very efficient one, and this fact has led to a large development in the application of steam turbines.

A section through such a compressor combined with its turbine is shown in Fig. 13, and it is seen that the compressor is very similar in construction to the steam turbine, having blades fixed on a revolving drum, and in a cylinder, which in this case on account of the small amount of compression to be done on the air are of uniform diameter. A dummy piston to balance the end pressure of the air on the moving blades is provided as in a steam turbine.

Such turbo blowing engines are largely used for blast furnaces, the blast pressures required ranging generally from 10 to 16 lbs. per square inch. One great feature of the turbine system is the way in which the blower adapts itself to

FIG. 11.

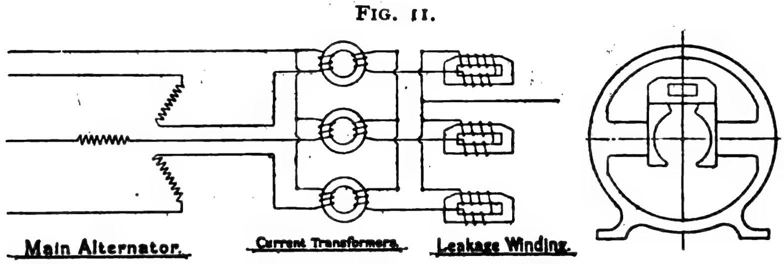


DIAGRAM OF CONNECTIONS. (Leakage Winding.)

A much larger output can be obtained by the adoption of some form of compounding which enables regulation again to be made as good as is desired. There are several means of doing this, one which is often used being the "Tirrill" regulator, where moving contacts regulated by the voltage of supply alter the excitation of the alternator. Another method which we have largely used is what we call a leakage path winding, shown diagramatically in Fig. 11, and this is a small yoke being put across the poles of the exciter round which the main current passes, and when this current increases it chokes back the magnetism and thus raises the voltage of the exciter. The effect of it is shown in Fig. 12 (p. 973), where will be seen the great difference in the regulation of the alternator with or without leakage paths.

An important development during the past few years has been the application of the steam turbine for driving air compressors. An

the requirements of the furnace. Should the resistance of the furnace diminish more air is at once automatically delivered by the turbo blower without the possibility of the engine racing. In fact the speed of revolution remains quite constant over a wide range of duty. Should, on the other hand, the resistance of the furnace increase, the quantity of air will be diminished and the pressure automatically increased. When what is known as "hanging" takes place it is an easy matter to speed up the turbine engine until the furnace is blowing freely. Usually about twice the normal working pressure can be obtained by this method.

Iron masters who use turbo blowers find that they can always get more iron from the furnaces when a turbo blower is supplying the blast than when it is supplied from a reciprocating engine. It is thus seen that the great elasticity and adaptability of such engines together with the steady blast is a great advantage in metallurgical work.

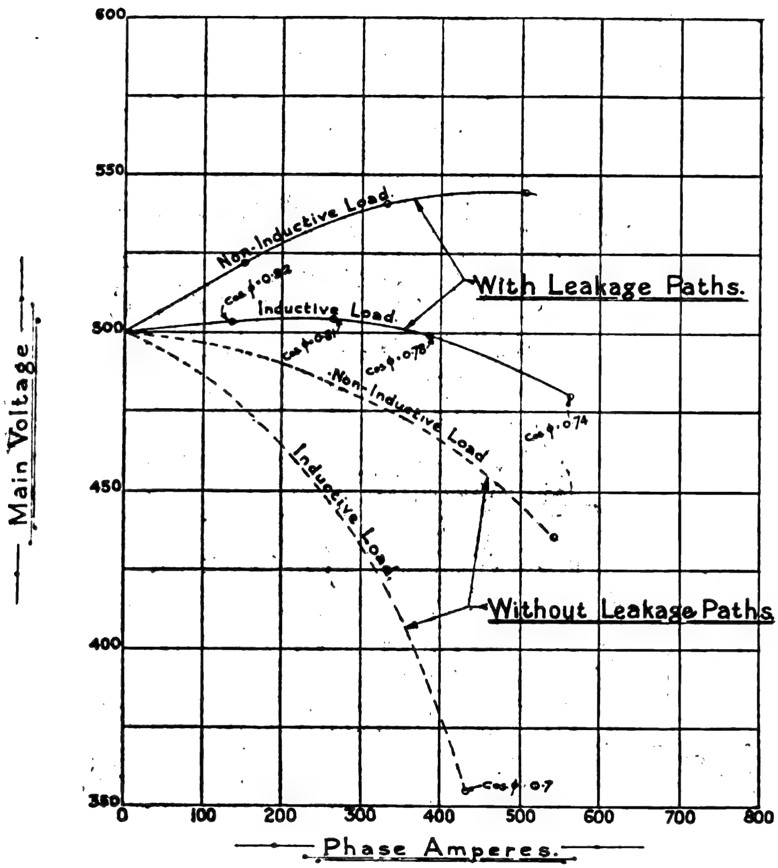
Fig. 14 (p. 975) shows an engine room in which both ordinary reciprocating blowing engines and tubine blowing engines are installed. The reciprocating engine is somewhat smaller in output than the turbine, and it is at once obvious what an enormous saving in space is effected by the use of the turbine engines. Further, it may be mentioned that the weight of the turbo-blowing engine complete is 25 tons, and the weight of the reciprocating engine 430 tons, or seventeen times heavier than the turbine.

A very useful size of plant is that built to deliver 20,000 cubic feet of free air per minute at 10 lbs. to 15 lbs. blast pressure. This size is suitable for blowing the average English blast furnace, and takes about 15,000 lbs. of steam per hour at 150 lbs. steam pressure, 100° superheat, and 28½″ vacuum, barometer 30″. From these figures it may be seen that turbo blowers are exceedingly economical. Besides iron smelting turbo blowers are used for copper refining and other metallurgical work. Small size turbo blowers are often driven by electric motors running at high speeds.

For producing pressures higher than 25 lbs. per square inch, the design of the blowing engine is usually of the centrifugal type, and consists of a number of centrifugal fans specially constructed to withstand the stresses caused by the high speed of revolution. The fans are arranged to blow in series, the pressure being slightly increased at each fan until the desired pressure is obtained, and in this way blowers are built to give 80 lbs. pressure, and above. This type of machine is used principally for mining operations, such as supplying compressed air for rock drills and coal-cutting machinery, and is found to be very economical.

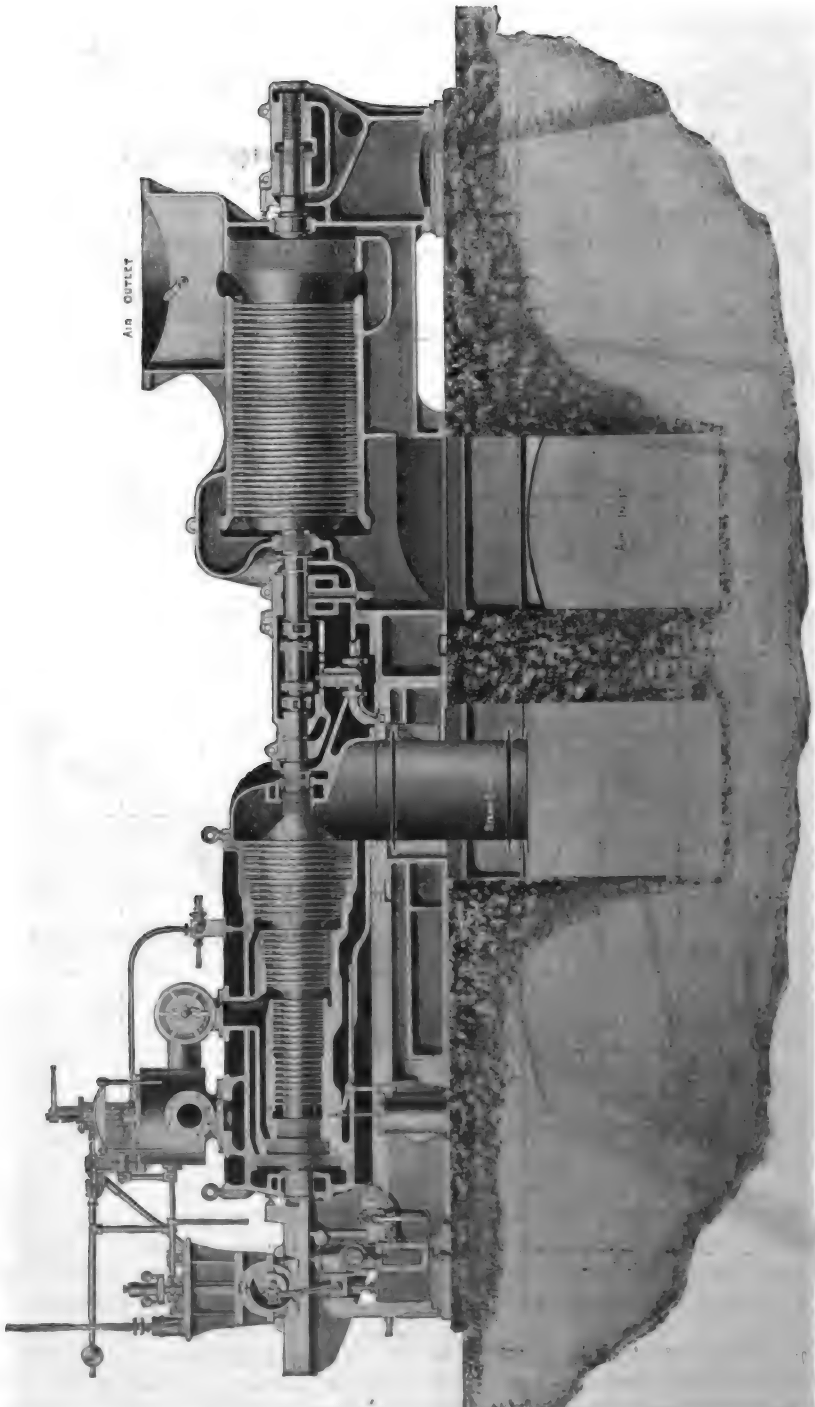
The fans are generally arranged in two cylinders, a high and a low pressure, with an

Fig. 12.



450-K.W. Turbo-Alternator Voltage Regulation Putting on Load. (Rheostats unaltered.)

FIG. 13.

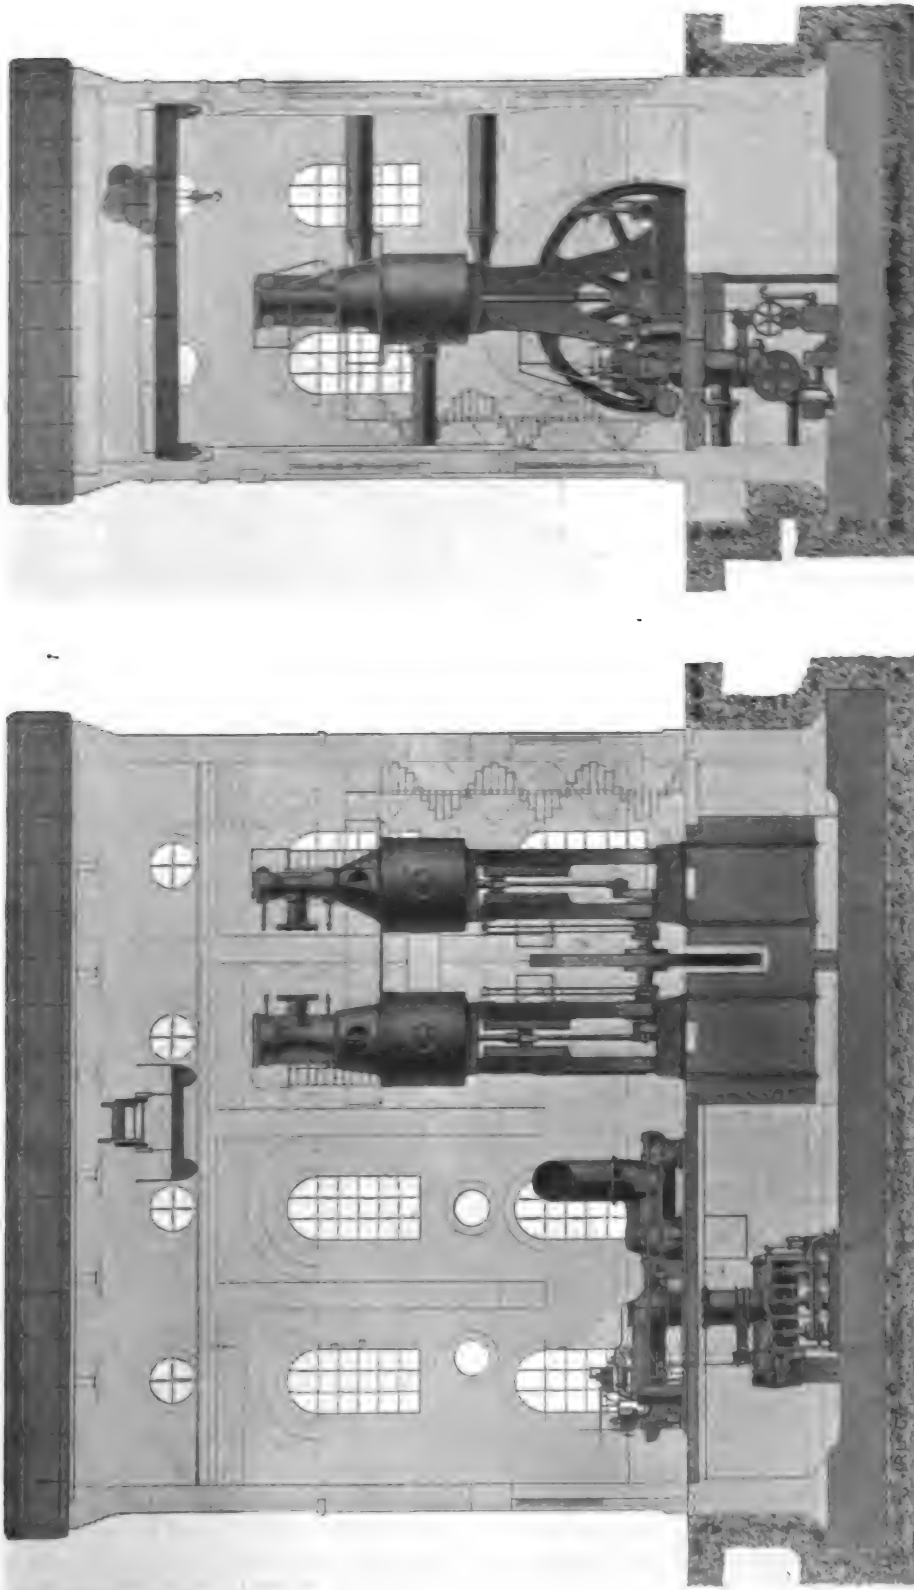


TURBO-BLOWING ENGINE. (Section through Steam and Air Turbine Cylinders.)

intercooler between them. The air is also cooled during compression by water-jacketing the cylinder.

A further development of the turbo compressor is for dealing with large volumes of gas or air at low pressures, and a number of this type designed to deal with about 30,000 cubic feet free air per minute at about 1 lb. pressure, have been made. They are used principally for drawing exhaust gases from

Fig. 14.



Installation of Turbo-blowing Engine and Condenser.

blast furnaces, and driving them through the by-product recovery plant. The gases from blast furnaces, more especially the Scotch blast furnaces, where coal is used instead of coke, are heavily charged with tar, ammonia, &c., and the usual form of reciprocating compressor has been found to be very troublesome, due to choking up, but since the turbo-machine came out, most gratifying results have been attained, the plants running for many months,

night and day, without ever being shut down.

Another application is that of boosting up the pressure of coal gas in the gas mains of large towns. Sometimes it is found that owing to the extension of a town the mains become too small. The introduction of small turbo blowers enables a large amount of gas to be forced through the small mains, and thus saves the heavy cost required to lay down additional mains to meet the increased demand for gas in the outlying districts.

In the Glasgow Corporation Gas Works, a small turbo blower is used for pumping gas down hill: this may seem rather paradoxical, but it must be remembered that coal gas is lighter than air, and therefore it has to be pushed down hill by mechanical means. The construction of this latter type of blower or exhauster as the case may be, is shown in Fig. 15. It will be seen that the particular machine illustrated, consists of three screws, very much like the propellers of a ship, only having more blades. Between the propellers, spiral guide rings are fitted. The power required to drive these machines is generally about 150 horse-power, and the speed of revolution about 7,500 revolutions per minute, varying of course with the size and duty of the engine.

EARLY STEAM NAVIGATION.

Mr. R. C. Seaton, writing to *The Times* Engineering Supplement on October 3rd, draws attention to the following paragraph in "Carlyle's Reminiscences" (Vol. I., pp. 128-130) on the subject of early steam navigation:—

"At Greenock I first saw steamers on the water; queer little dumpy things, with a red sail to each, and legible name, *Defiance*, and such like, bobbing about there, and making continual passages to Glasgow as their business. Not till about two years later (1819 if I mistake not) did Forth see a steamer; Forth's first was far bigger than the Greenock ones, and called itself *The Tug*, being intended for towing ships in those narrow waters, as I have often seen it doing; *it* still, and no rival or congener, till (in 1825) Leith, spurred on by one Bain, a kind of scientific half-pay Master R.N., got up a large, finely-appointed steamer, or pair of steamers, for London; which, so successful were they, all ports then set to imitating. London alone still held back for a good few years; London was notably shy of the steamship, great as are its doings now in that line. An old friend of mine, the late Mr. Strachey, has told me that in his schooldays he at one time—early in the nineties I should guess, say 1793—used to see, in crossing Westminster Bridge, a little model steamship paddling to and fro between him and Blackfriars Bridge, with steam funnel, paddle-wheels, and the other outfit, exhibiting and recommending itself to London and whatever scientific or other spirit of marine adventure London might have. London entirely dead to the phenomenon, which had to duck under and dive across the Atlantic before London saw it again, when a new generation had arisen. The real inventor of steamships, I have learned credibly elsewhere, the maker and proprietor of that fruitless model on the Thames, was Mr. Miller, Laird of Dalswinton, in Dumfriesshire (Poet Burns's landlord), who spent his life and his estate in that adventure, and is not now to be heard of in those parts; having had to sell Dalswinton and die *quasi*-bankrupt (and I should think broken-hearted) after that completing of his painful invention and finding London and mankind dead to it. Miller's assistant and work-hand for many years was John Bell, a joiner in the neighbouring village of Thornhill. Miller being ruined, Bell was out of work and connexion, emigrated to New York, and there speaking much of his old master, and glorious unheeded invention well-known to Bell in all its outlines or details, at length found one Fulton to listen to him: and by 'Fulton and Bell' (about 1809), an actual packet steamer was got launched, and, lucratively plying on the Hudson River, became the miracle of Yankeeland, and gradually of all lands. These I believe are essentially the facts. Old Robert McQueen of Thornhill, Strachey of the India House, and many other bits of good testimony and indication, once far apart, curiously coalescing and corresponding for me. And as, possibly enough, the story is not now known in whole to anybody but myself, it may go in here as a digression—*à propos* of these brisk little Greenock steamers which I first saw, and still so vividly remember, little *Defiance*, &c., saucily bounding about with their red sails in the sun, on this my tour with Irving."

The interesting point about the paragraph is that these reminiscences of Carlyle do not seem to have previously attracted the attention of writers on early steam navigation. Their publication is indeed subsequent to that of the principal authorities. Probably all that is to be said on the subject has been said long ago, and there is no great likelihood of any fresh information coming to light.

Interesting and picturesque as Carlyle's remini scences are, they contain several inaccuracies. He was not correct in supposing that it was Miller's model which ran on the Thames about 1793. This was really Rumsey's boat, described in his patent of the 6th of November, 1788. Rumsey was an American who came over to England to push his invention. Woodcroft says it was on account of his being unable to obtain a patent in America. but according to Thurston, he obtained a patent from the State of Virginia in 1787. After two years in preparations "he was on the eve of putting the last hand to his steamboat when he died."

(Woodcroft on "Steam Navigation"). He was explaining a friend's invention to a committee of the Society of Arts in 1792 when he was struck by an attack of apoplexy, which caused his death in a few hours. The vessel was, however, got afloat in February, 1793, and was "sailed many times on the Thames against wind and tide with the speed of four knots an hour." The boat is fully described in Woodcroft's paper on "Steam Navigation" in the Proceedings of the Society, Vol. LVI., 1846-8.

Miller's historical experiment on the Dalswinton lake was carried out in 1787. The steam engine used was Symington's. No reference to John Bell appears in Woodcroft, or in the very full memoir of Miller in the "Dictionary of National Biography" (by Mr. R. B. Prosser); nor is he mentioned by Galloway or Thurston in their histories of the steam engine. Henry Bell, whose *Comet*, launched in 1812, ran regularly for some time between Greenock and Glasgow, is said by Galloway "to have obtained information from Fulton," but no authority is given for the statement. Fulton's *Clermont* was launched in 1807 in New York, with an engine supplied by Boulton and Watt.

The statement that Miller sold his property and died insolvent is certainly incorrect. He died at Dalswinton in 1815, and the division of his property among his children was the subject of a lawsuit, which was carried to the House of Lords.

The first practical steamboat was, without much question, the *Charlotte Dundas*, which, in 1802, was tried on the Forth and Clyde Canal, and would have been adopted for use on that canal, but for the fear of the proprietors of damage to the banks, and on the Bridgewater Canals, but for the death of the Duke of Bridgewater.

The whole question of the origin of steam navigation has been a little obscured by the patriotic proclivities of American and English historians. Probably the history may be summarised as follows:—The first experimental vessel successfully driven by steam was that of Miller, who, in 1787, at the suggestion of Taylor, fitted a Symington engine into his double-hulled boat, and worked it on Dalswinton Lake. The second—still experimental—was Rumsey's boat, which was tried on the Thames in 1793. The first practical steamboat was Symington's *Charlotte Dundas*, which successfully ran, and towed boats on the Forth and Clyde Canal in 1802. The first steamer which ran regularly and continuously was Thomas Fulton's *Clermont*, 1807. The first regular passenger steamer in Europe was Henry Bell's *Comet*, 1812. H. T. W.

THE BY-PRODUCTS OF INDIAN FORESTS.

It has been demonstrated by numerous experiments in Europe as well as in America that the pulp possessing the best fibre for paper, and the most practicable to make is that derived from the wood of the spruce and fir. In India there are spruce and fir which yield as good paper pulp as any in Europe or America, as has been amply proved by experiments. Large quantities of this timber in India will run 4 feet and 5 feet in diameter, 4½ feet from the ground, and 150 feet to 200 feet in height. They not only do not use a stick of this, but even, in some places, they girdle it and allow it to rot, just to favour a few deodars (*Cedrus deodara*) growing under it. The reason for this is the difficulty of securing the timber, which could be overcome by energy and enterprise. The difficulty of removing the timber is due to the extremely rugged nature of the country, the steep slopes and gorge-like valleys rendering the construction of railways, or even cart roads, so expensive as to be practically out of the question, except for very large operations. The American Consul-General at Calcutta, who has been studying the forests of India, and incidentally their properties as pulp and turpentine producers, says that though the amount of material obtained per acre would be small on account of the forest conservation by the Government, this could be overcome by establishing a wood-pulp mill on one of the main streams, such as the Jumna or the Tons—or, preferably, at their junctions—so as to tap a larger area. From there the manufactured product, either pulp or finished paper, could easily be shipped by rail. The difficulty of the number of small operations would be overcome by the extreme cheapness of the labour. Felling with the primitive tools used costs less than two shillings per 1,000 feet, board measure, and carriage by coolies costs about one penny per cubic foot per mile. The rolling down hill would cost practically nothing. The advantages which the wood-pulp industry would enjoy would be an absolutely assured and permanent supply of raw material, on account of the conservative management by the Government of the forests from which the material is derived, and the favour and help of the Government in forwarding the enterprise, which is only too anxious to have it succeed, so as to furnish a market for the spruce and fir, which at present are rotting, and going to waste. Another advantage, especially important for an industry in India, is the favourable climate. On account of the elevation at which the tree occurs, the climate is such that the work can be carried on by white men, without danger to their health, or impairment of efficiency, all the year round. Here, then, is said to be an opportunity of developing an industry which would be not only extremely profitable, but absolutely sure and permanent when once started. As regards a turpentine industry, the making of turpentine in India offers even a more inviting field for enterprise then the pulp industry, because it has been tried long enough for all the figures and details to be fully known. Turpentine in India is derived from the chir, or long leaf pine, which very much resembles the American long leaf pine, from which the main supply of turpentine of the world is derived, and which is rapidly disappearing. The tree occurs in different parts of the

Himalayas at elevations of from 3,500 to 7,000 feet. It is worked in several localities, but most at Bohwali, near Naini Tal, in the United Provinces. Here the Government have been tapping and distilling since 1900. The work of tapping is well organised, and the distillery is fitted up with most of the modern improvements. From one maund (82 pounds) of crude resin, one gallon and a-half of turpentine is obtained, and fifty-three pounds of resin. This yields a profit of about five shillings and sixpence per maund. It takes about seven trees to produce a maund in a year, thus giving a profit of about ninepence per tree per annum. This comprises everything except interest on the capital. In the Bohwali district there are more than 300,000 trees available. The Consul says that the Government is now trying to sell out because its policy has always been to encourage a new industry by undertaking it itself, and demonstrating that it is profitable, then stepping out and giving it over to private enterprise, because it wants every industry to be in the hands of private individuals as far as possible. The Consul adds that there is an opportunity here to buy up an industry already developed, the profit of which has been clearly proved, and one which is bound to increase in value and extent, because it has only just passed the experimental stage, and they are still tapping much more slowly than there is any need for.

ORIGIN OF SHEFFIELD PLATE.

There is nothing in art so entirely English as the making of Sheffield plate, mezzotint engraving not excepted. The fusing of silver on to copper was known to the ancient Peruvians, possibly to other nations, but as far as Western civilisation is concerned the discovery was made by that "ingenious mechanic," Thomas Bolsover, in 1732. Like many other important discoveries, that of Bolsover was the result of an accident. One day when repairing a piece of plate he is said to have used a penny to "cramp" up a join, and allowing his work to become overheated, found that the two metals had fused and become inseparable.

In the middle of the eighteenth century silver was costly, and Bolsover conceived the idea of beating out a thin layer of the precious metal and fusing it on to a copper foundation, thus producing something cheaper than silver plate and better than pewter.

In a few years from Bolsover's discovery the making of Sheffield plate had become a flourishing industry, and the workers, "as a body, most unsteady, depraved, and idle," earned such high pay that two are said to have kept hunters, whilst others employed a hairdresser to attend them during working hours "with his paraphernalia, powder, and all." But this was the golden age produced by the scarcity of capable workmen. Soon a class of skilled mechanics sprang up, and masters were no longer forced to bid against each other for the possession of craftsmen capable of carrying on the new and popular industry. —*The Art Craftsman.*

HOME INDUSTRIES.

Banks and Home Industries. — Attempts have been made during the discussion of the Development Bill in the House of Commons to induce the Government to promise support to industrial banks intended to assist farmers and others, but nothing definite in this direction has been achieved. In Germany the greatest assistance has been rendered to agriculture by the Raiffeisen credit banks, which have gone far towards the solution of an agricultural difficulty in this country—the lack of easy and advantageous ways of procuring ready money when it is most needed. There are the legitimate banks and the loan agencies, good and bad, but in resorting to either the farmer is compelled to pay a high rate of interest, and without substantial security he cannot succeed in borrowing money at all. In Prussia one of the most useful auxiliaries of the co-operative credit societies is the institution known as the Central Co-operative Bank, a State institution established with ample resources for the purpose of providing needy co-operative credit societies with funds. Probably before many years have passed something of the sort will be tried in this country. Nor is it only agriculturists who complain of the lack of banking accommodation in the United Kingdom. The growth of the joint stock banks, with the consequent disappearance of the private banks, has resulted in industrial concerns being nowadays unable to get that financial assistance which the private banks accorded them, and which is to be got in full measure in Germany and other Continental countries. The joint stock banks are content to earn their dividends on the exchange and discounting business, and look askance at industrial issues which may involve speculation and risk. As a writer in *The Times* points out in an interesting communication (October 9), the banks are not interested in industrial undertakings to the extent that they used to be in this country and still are on the Continent. "In times past the banks in manufacturing towns were privately owned, the banker was interested in local manufacturing concerns, probably having a seat on the board of directors, and when large contracts had to be undertaken, or times of stress arose, the manufacturer could rely upon the support of the local bank." But with the disappearance of the private bank this assistance disappears. The local banks have now been amalgamated with the big London banks, and co-operation with local industries has ceased. The local bank manager has become a paid official, little better than a clerk, liable to be moved about at any time, and having to refer to London upon all matters not of the merest routine. The authorities in London are not to be blamed, for, to use a homely adage, they have to cut their coat according to their cloth. The banking business of the country is based on a dangerously low gold reserve, the trading capital belongs to the depositors, and is mostly repayable on demand; and the paid-up capital of the shareholders

is very small in comparison with the business done. But this state of things is seriously affecting the home industries of the country. The writer already quoted goes so far as to say that "the effect has been that in certain classes of work in London, where finance and contracting have to go together, it has become a rule that 'no British firm need apply,' not because Continental machinery is cheaper or of better quality than the English, but because the Continental manufacturer, thanks to the support of his banking institutions, is able to take up concessions, finance work, and accept terms of payment at which the English firm cannot look. It used to be said that "trade follows the flag;" it is truer, however, to say that it follows the bank.

Mushroom Insurance Companies.—The report of the Comptroller of the Companies' Department of the Board of Trade, just issued, refers to the insurance companies which passed into liquidation last year. Their history affords additional proof of the need for the strengthening of the law relating to insurance companies which the Insurance Bill now before Parliament is intended to provide. The British United Insurance Corporation, Limited, lived just two years and five months. Its only capital was the sum of £2,690 derived from £3,590 share capital issued. With these slender means the company accepted unlimited risks (estimated roughly at £1,100,000), and undertook insurances of almost all kinds, including endowment and house purchase. Life insurance was not undertaken, so that no statutory deposit of £20,000 was necessary. Efforts were made to obtain more funds without success. The usiness was carried on recklessly in the meantime, all risks offered being accepted, with the inevitable result of failure. The other case was that of the Casualty Insurance Company, Limited, registered in February, 1904, with a nominal capital of £60,000, for the purpose of carrying on the business of personal accident and sickness insurance. The subscribed capital was £13,595, of which only £5,528 10s. was paid up. Not undertaking life insurance, no deposit could be required of the company prior to commencing business, and its uncalled capital of £8,047 therefore formed the only reserve to meet losses which might arise of an unusual nature. In cases where the company insured against fatal accidents re-insurances were effected by it with other companies, but the small capital available proved quite insufficient, with the result that it was all lost, and the creditors will receive no more than a very small dividend.

Monster Steamships.—The Cunard Steamship Company having beaten the record with regard to size and speed in the construction of the *Mauretania* and *Lusitania*, the White Star Line are building two steamers for the North Atlantic Service which in point of size leave all vessels now afloat far behind. The tonnage of the *Mauretania* is 33,000 and the *Lusitania* is a sister ship, but the tonnage of the *Olympic* and *Titanic* is to be 45,000 tons though with a speed of only 21 knots as against the 25 of the Cunard boats. The new steamers, which will be completed about the end of 1910, will sail on the Southampton-New York Service, and will have a displacement of 60,000 tons. They are to be 840 feet long, with a beam of 90 feet, and the boat deck will be more than 60 feet above water. Their carrying capacity will exceed that of any existing ship by at least one-third, and they will carry more than 5,000 persons all told, the crew of each exceeding 600 in all. Nor is it only in size that the vessels will beat the record. They will be more elaborately fitted than any now afloat. The passenger may well imagine himself in a sumptuous hotel ashore. There will be not only suites of rooms but complete flats at his disposal if he cares to pay for them; cabins with private shower baths attached: a magnificent gymnasium; a verandah café on one of the upper decks 50 feet above the water; a palm garden, and a garden on the fore deck. Each boat will be divided into upwards of 30 steel compartments separated by heavy bulkheads. Another set of safety devices will guard against fire. A combination of turbine and reciprocating engines will propel the vessels, and this arrangement is expected to effect a great economy of coal.

Short Time in the Cotton Trade.—The International Federation of Master Cotton Spinners' and Manufacturers' Associations has issued the statistics which it has collected showing the consumption of cotton in the world in the year ended 31st August last, and the stocks of cotton in spinners' hands at that date. In some of the principal countries the actual mill stocks of American cotton are considerably larger than appeared from the estimates recently made by some authorities. On the 31st August the stocks in actual bales reached a total of 3,183,392, as against 2,728,045 a year before, 3,334,410 in 1907, and 1,210,610 in 1906. The American stocks were 908,000 bales. Russia came next with 345,644. The British total was 331,741, and Germany's 333,669. An interesting part of the return is that which deals with short time. The short time movement initiated by the International Federation is now adopted by almost every country of the world. No figures have been cabled from the United States as to short time, but it is known that during part of 1908 a considerable amount of short time was worked in America, and that a number of spindles were stopped throughout the year. Tables given by the Federation estimate the total number of spinning spindles at work in the world in the past year at 131,503,062, of which 53,311,630 are credited to Great Britain, 10,162,908 to Germany, 5,800,000 to India, and 27,783,000 to the United States. The number in France is put at 7,000,000, and in Russia at 7,800,000, Japan having 1,496,698.

The American Cotton Crop.—The two reports from the United States Government just issued upon

the cotton crop of the present year do not throw much light upon the situation. From the first of these it appears that up to September 25th there had been ginned of the present American crop 2,562,000 bales, as compared with 2,590,639 bales at the corresponding time last season. These figures do not in themselves bear out the reports of a greatly diminished supply. But it is said by those who predict a short crop that hot weather has forced the cotton into a premature fruition, and that in some districts at least the period of growth will be abnormally short. The high prices, too, are said to have stimulated the movement to market. Nor does it necessarily follow that a large September movement means a large crop. The second of the two reports mentioned above, which seeks to obtain an average "condition" of the crop, or such part of it as was ingathered on September 25th, cannot be said to be encouraging. This condition is given as 58·5 per cent. of the possible, or rather impossible maximum contemplated by the Government office, and it compares with 69·7 per cent. last year. The one safe prediction at present about the current year's cotton crop seems to be that it will not be a big one.

CORRESPONDENCE.

KAPOK LIFEBELTS IN THE ROYAL NATIONAL LIFEBOAT INSTITUTION.

With reference to the article entitled "The Production of Kapok in Java," which appeared in the *Journal* on July 23rd, 1909, Commander W. Holmes, R.N., Chief Inspector of Lifeboats, has kindly supplied the following information relating to the use of kapok life-belts by the Royal National Lifeboat Institution:—

In the year 1904 kapok was brought to the notice of the Committee of Management of the National Lifeboat Institution as a substitute for the cork used in the life-belts invented by the late Admiral J. Ross Ward in 1854, and supplied to lifeboat crews ever since that date. After experiments had been made and a pattern life-belt approved, the kapok belts were sent to 10 coast stations for trial on service, and the coxswains and crews were especially invited to express their opinion on them. In July, 1906, reports were received after the belts had been 12 months on the coast, and the coxswains and crews all spoke most highly of them, much preferring them to the old cork belts, the chief points in favour of the kapok being lightness, more freedom to work in, ease in putting on, comfort, and warmth. The Committee of Management thereupon adopted the kapok life-belt for all future supplies, and at this time (1909) there are not many cork belts left on the coast. The following details will illustrate the great advantages of kapok:—

	Average weight.	Tested to support in water 24 hours.
Cork belts	6 lbs.	...... 22 lbs.
Kapok belts ..	3 lbs. 12 oz.	...... 25 lbs.

The requisite qualities of a lifeboat man's life-belt are:—

1. Extra buoyancy of 22 lbs. sufficient to support a man heavily clothed, with his head and shoulders above the water, or to enable him to support another person besides himself.

2. Perfect flexibility, so as readily to conform to the shape of the wearer.

3. A division into two zones, an upper and a lower, so that between the two, it may be secured tightly round the waist; for in no other manner can it be confined sufficiently closely and securely round the body without such pressure over the chest and ribs as to affect materially the free action of the lungs, impede the muscular movement of the chest and arms, and thereby diminish the power of endurance of fatigue, which in rowing boats is a matter of vital importance.

4. Strength, durability and non-liability to injury.

All the above conditions are satisfied far better by kapok than by cork in the construction of lifebelts.

OBITUARY.

Richard Bannister.—Mr. Richard Bannister, who had been a member of the Royal Society of Arts since 1886, died at the age of 74 on the 27th ult. Mr. Bannister was a student under Dr. Hofmann at the Royal College of Chemistry, and entered the Government Laboratory in 1862. In 1874 he became Deputy Principal of the Laboratory under the late Dr. Bell. He retired from the Government service in 1898. Mr. Bannister was one of the first shareholders of the Civil Service Supply Association, and after serving for several years on the Committee of Management, he became Chairman in 1886; he held this office up to the time of his death.

He was a recognised authority in all matters connected with the chemistry of food, and had great practical knowledge of the subject. He served as a Juror at the Health and Inventions Exhibitions, at South Kensington, in 1884 and 1885, and contributed a report on wines, &c., to the volume of Reports on the Colonial and Indian Exhibition, 1886, published by the Society of Arts for the Royal Commission of that Exhibition. He was also a Juror at the two last Paris Exhibitions, 1889 and 1900, and at Chicago in 1893. He was often called upon to give evidence before Royal Commissions and Departmental Committees dealing with food and similar subjects, and had great experience as an expert witness in Revenue cases.

Mr. Bannister gave the Society two courses of Cantor Lectures, one in 1888 on "Our Milk, Butter, and Cheese Supply," and the second in 1890, on "Sugar, Coffee, Tea and Cocoa." He also, in 1887, read a paper on "Colonial Wines," for which he was awarded a silver medal.

NOTES ON BOOKS.

The Recognition of Minerals. By C. G. Moore, M.A., F.I.C. London: *The Mining Journal*. 7s. 6d. net.

The object of this book is to assist the traveller and prospector in distinguishing minerals of commercial value from ordinary rocks and stones. It originated in a series of notes made by the author when he was engaged as resident chemist to the Ashanti Goldfields Corporation, and additions have been made to it during professional journeys to Tasmania and elsewhere. Descriptions are given of most minerals of value, with hints on how to recognise them, the uses to which they are put, and the demand generally existing for them. Simple tests, such as can be easily performed in the field, are included, though no attempt is made to enter into detail into the various methods of assay, which are the province of the highly-trained mineralogist. The book should prove useful to that large number of travellers who are passing through mineralised districts in the less known parts of the world: even if it does not assist them to discover great riches it will repay them, as the author says, "in the added interest that such a study gives to residence abroad under conditions that are sometimes monotonous or unprofitable."

Botany of To-day. By G. F. Scott Elliot, M.A., B.Sc., F.R.G.S. London: Seeley and Co. 5s. net.

The "Science of To-day" series has already made its mark as giving excellent popular accounts of recent developments in various branches of science. The latest volume is worthy to rank with its predecessors, which dealt with astronomy, electricity, and physics. To recapitulate and describe in a lucid and readable form the present situation in the science of botany is no easy task, for perhaps in no field are more rapid strides being made at this time. Mr. Elliot estimates that over a quarter of a million printed pages, often of a very difficult and technical character, and written in eight or nine different languages, form the present yearly output of botanical writers; and with such frequency is new work being brought forward that between the printing and publication of this volume several books of the first importance appeared. But although this volume was written before the author had had an opportunity of seeing the English edition of Warming's "Oecology" and Seward's "Darwin and Modern Thought," it contains all but the very latest botanical theories, and the reader who has mastered it will have an excellent general idea of recent problems and discoveries of botanists.

Modern Cabinet Work, Furniture and Fitments. By Percy A. Wells and John Hooper. London: B. T. Batsford. 12s. 6d. net.

The aim of the authors has been to produce a book dealing fully with the modern developments and progress of the craft of cabinet-making, and to illustrate "step by step the practice of the craft in all its applications, from the making of a joint to the preparation, setting out, and complete construction of the numerous and various types of furniture and woodwork which the cabinet-maker is called upon to make." It will be obvious at once that the scope projected is a very wide one; and though probably no one is better fitted to undertake the task than Mr. Wells, whose paper on "English Furniture" won him the Society's silver medal last session, it may be doubted whether it was advisable to design a book which should appeal at the same time to the apprentice and journeyman, the foreman, draughtsman, and designer, the salesman, architect, and collector. The description and illustrations of tools, for instance, which may interest the apprentice, will hardly be wanted by the more advanced student. But when this piece of criticism has been offered, nothing but praise remains for the book. To give an idea of the pains which have been bestowed on its production, it may be mentioned that it includes 1,000 diagrams and measured drawings; more than fifty photographs of historic and modern work; and detailed descriptions of over two hundred woods used in furniture making, with notes on the growth and structure of timber, its diseases, shrinkage, seasoning, &c. A glossary of technical and workshop terms and a copious index complete a very handsome volume.

GENERAL NOTES.

Books on Agriculture.—Mr. A. D. Hall is publishing, through Mr. John Murray, a new edition of his book, "The Soil," and also a new work, "Fertilisers and Manures." The latter seems to embody with other material the information contained in the course of Cantor Lectures delivered before the Society by Mr. Hall.

Studentships at the School of Art Wood-Carving.—The School of Art Wood-Carving, 39, Thurloe-place, South Kensington, has been re-opened after the usual summer vacation. Some of the free studentships in the Evening Classes maintained by means of funds granted to the school by the London County Council are vacant. The holders of these studentships are selected by the London Council, and by the committee of the school, from persons of the industrial class who are intending to earn their living by wood-carving. Candidates must have passed at least one of the examinations of the Board of Education in freehand drawing. Those who have some knowledge of wood-carving, or have passed in other subjects of art, will be preferred. The day classes of the school are held from 10 to 1 and 2 till 5 on five days of the week, and from 10 to 1 on Saturdays. The evening class meets on three evenings a week and on Saturday afternoons. Forms of application for the free studentships and any further particulars relating to the school may be obtained from the manager.

Journal of the Royal Society of Arts.

FRIDAY, OCTOBER 22, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

STEAM TURBINES.

By Gerald Stoney,
B.E., M.Inst.C.E., M.I.E.E.

Lecture III.—Delivered April 5th, 1909.

In the last two lectures a description was given of, firstly, the lines on which steam turbines are constructed and designed, and secondly, their various applications on land.

In this lecture some account is given of the greatest development in the application of the steam turbine, that is, to the propulsion of ships.

The large and increasing amount of horse-power, and the greater size and speed of the modern engines tend towards some form which shall be light, capable of perfect balancing, and economical in steam. The marine engine of the piston type does not fulfil these requirements. In January, 1894, a pioneer syndicate was formed to explore the application of the steam turbine to marine propulsion. It was deemed expedient, for reasons of economy and also of time (as many alterations were anticipated) to build as small a vessel as possible, but not so small as to preclude the attainment of an unprecedented rate of speed. The *Turbinia* was constructed, her dimensions being 100 feet in length, 9 feet beam, 3 feet draught of hull, and 44 tons displacement. She was fitted with turbine engines of 2,000 actual horse-power with an expansive ratio of 150-fold, also with a water-tube boiler of great power and of the express small tube type. The turbine engines consisted of three separate turbines—a high pressure, an intermediate, and a low pressure—each driving one screw shaft independently. To the low pressure on centre shaft the reversing turbine for going astern was also coupled, and on each shaft were keyed three propellers of small diameter and of normal pitch ratio. This arrangement was found to be the best after many trials. The maximum indicated horse-power that has been obtained on runs of about five miles duration has been 2,500, giving a speed of 34½ knots, but a speed of 31 knots can be maintained for about two hours' duration, and since she was completed she has run several thousands of miles, sometimes in very heavy seas, and the main engines have never caused a moment's anxiety, nor have any repairs to them been necessary. But before this result was obtained a great deal of trouble had been given by the phenomena of cavitation, which is the vacuum left behind the blades of a screw propeller if it is forced too hard through the water. If we put a stick into water and move it slowly, the water follows up the stick and closes in behind it, but if we move it too violently a space is formed in the water, as it cannot close in behind the stick fast enough. The same thing occurs in screw propellers if the forces applied to them are too great. Mr. Parsons investigated this in a very beautiful way by allowing an intermittent beam of light to fall on a model propeller at one part of its revolution, so that it seemed as if it were standing steady, and thus the cavities about the blades could be clearly seen and photographed.

Thus it will be seen that after three years' hard work and many failures the *Turbinia* was completed, and in her the problem of adapting the turbine to work a screw propeller was worked out and, like almost everything else in engineering, resulted in a compromise.

The screws were made of small diameter and with broad blades so as to avoid cavitation and yet revolve as quickly as possible, and the turbines were made short and of large diameter so as to revolve as slowly as possible. In order still further to make them adapt themselves to one another each shaft was fitted with three screws sufficiently far apart to prevent serious interference, and thus each screw had only to

absorb one-third of the power transmitted by the shaft; and also the turbine was divided into three—a high pressure, an intermediate, and a low pressure, so that there was only one-third of the expansion in each. This enabled the drums to be made short and of large diameter, and yet have a good height of blade so as to minimise leakage.

In the first lecture it was shown that for any given amount of expansion and a given velocity ratio, a certain spindle volume was necessary for good economy. By thus dividing up the turbine into three parts each had only one-third of the total volume, and at the same time the blades were three times as high as if there were three separate turbines, each with drums of the same diameters as the divided ones. Also, since the expansion in each is moderate, there is no need to step the drums, and thus they are cylinders of one diameter only, very short and stiff, and enabling fine clearances to be used.

The total result was that the weight was probably about one-third and the leakage one-quarter of what there would have been with three separate turbines, each having the full expansion carried out in it, and it was this dividing up of the turbines that more than anything else made the *Turbinia* the success she was. A separate stern turbine was fitted on the centre shaft for going astern. After the *Turbinia*, the *Viper* and *Cobra*, torpedo-boat destroyers, followed, but the next great step was the introduction of the turbine into the Mercantile Marine.

Many conferences were held between Mr. Parsons, Mr. Archibald Denny, and Captain John Williamson, and finally, as a result, the *King Edward* was built in 1902 at Dumbarton, the engines being made by the Parsons Marine Steam Turbine Co., of Wallsend. The arrangement of the turbines was altered considerably from that of the *Turbinia* in order to get increased manœuvring power. Three shafts were still retained, with two screws on the wing shafts and one on the centre shaft, which revolved at rather lower speed; but, instead of all the three turbines being in series, the steam passed first through the centre high pressure one, and then was divided between two low pressure turbines, port and starboard. In the same casing as these low pressure turbines, and at the exhaust end, the stern turbines were incorporated. Such turbines are shown in Figs. 16 and 17. This gave much better manœuvring power than with the arrangement in the *Turbinia*, as when manœuvring the high pressure turbine was cut out and steam admitted direct to either or both of the low pressure turbines or to the stern turbines, thus giving as good manœuvring power as in the case of a twin-screw ship with reciprocating engines.

The success of the *King Edward* was the starting point for the success of the turbine in the Mercantile Marine for ships above about 18 knots, and it may be worth while to consider in what that success consisted.

At sea as well as on land one of the most important questions is coal consumption, and it was found by Messrs. Denny that this was some 20 per cent. less than in the case of similar vessels with reciprocating engines; also the cost of oil, which generally amounts to something like 5 per cent. of the coal bill, was reduced to well under 1 per cent., and at the same time the upkeep of the machinery was found to be very small, and it was most reliable. Vibration was also less, and the necessary engine-room staff much reduced.

The success of the *King Edward*, together with that of the *Viper* and *Cobra*, led the Admiralty to have turbines fitted into one of four third-class cruisers, and the vessel chosen was the *Amethyst*. Extensive trials were carried out between her and her sister ship, the *Topaz*, with reciprocating engines, each being 350 long and of 3,000 tons displacement. The turbine engines were similar to those described in the case of the *King Edward*, only cruising turbines were added to give better economy at low speeds, while the reciprocating engines were of the usual triple expansion, Admiralty type. The result was that at all speeds above 14 knots the turbine was the more economical, being 15 per cent. better at 18 knots, 31 per cent. better at 20½ knots, and 38 per cent. better at 22·1 knots. At full power on the same coal consumption the *Amethyst* with the turbine engines developed 42 per cent. more power than the *Topaz*, while on the specified coal consumption the speed was 23·6 knots, as against 21·1 knots, or 2½ knots more, representing an extra power of about 37 per cent. Another way of looking at the results is that at 20 knots the turbine ship has a radius of action of 3,600 nautical miles, while that with a reciprocator has only a radius of action of 2,000 nautical miles, or little more than half.

With cross-channel boats it has been found that the turbine vessels use 25 per cent. less coal per passenger and travel two knots faster than those with reciprocating engines, and the

Lusitania has been shown by Sir William White to be 16 per cent. more efficient than the great German reciprocating liners.

Nineteen hundred and six was a notable year in the history of the Marine Steam Turbine, for in it two great events occurred—the Admiralty decided to fit turbines in all new fighting ships, and the Commission appointed to consider the question of the 25-knot Atlantic liners to be built by the Cunard Company decided on turbines instead of reciprocating engines for these great vessels.

The Admiralty went up from the 15,000 horse-power of the *Amethyst* to the 23,000 horse-power of the *Dreadnought* and the 41,000 horse-power of the *Indomitable*—a gradual rise, it is true, but a great one when one considers the large number of vessels involved and that it affected practically the whole shipbuilding programme of Great Britain.

The Cunard Commission went up from the 8,000 horse-power of the cross-channel boat *Queen* to the 70,000 horse-power of the *Mauretania* and *Lusitania* in a single step, a thing requiring the greatest courage and confidence on the part of the late Lord Inverclyde and the rest of the Cunard Company, for there was always the great danger of building another *Great Eastern*, and having a huge "white elephant," as Brunel had in the middle of the last century. How successful these ships have been has been proved by the recent trip of the *Mauretania*, in which she crossed the Atlantic in less than 4½ days at an average speed of just 26 knots.

In these Cunarders each low pressure turbine weighs about 300 tons, is some 50 feet in length and 17 feet 6 inches in diameter; in the *Queen* they were only 25 tons weight, 20 feet long, and 6 feet in diameter.

Such a departure necessitated the most careful consideration of the effect of expansion on the various parts and of the deflections due both to difference of temperature, stresses due to rolling and pitching at sea, and the weight of the structure, for in engineering there is more danger in going from a small structure to a large than in anything else, as stresses go up in all directions and the whole tends to become relatively less rigid.

In these vessels on account of their great size it was decided to have four shafts, both to reduce the size of the turbines and to give increased reliability in case of accident. Thus each side, port and starboard, is complete in itself, having a high pressure and a low pressure turbine on separate shafts, and to reduce the size of the low pressure turbine the arrangement in the *Turbinia* was reverted to of separate stern turbines fitted on the high pressure shafts, which in this instance were the wing ones.

How effective this was will be seen when it is remembered that when the *Mauretania* lost a screw in consequence of striking some wreckage in the Atlantic she was still enabled to run the rest of the season with one turbine out of action at a loss of speed of only about two knots, and when a further accident caused the loss of another screw she still was enabled to cross the Atlantic at a fair speed. This seems to be about the greatest test that the reliability of these great ships could be put to.

In the case of warships also, especially of large size, a similar arrangement of four shafts is adopted, and such an arrangement has the great advantage that each set of engines is completely independent of the other, and thus, although one may be disabled by gun fire or torpedo, the other is unaffected, a condition which it is not possible to arrange with three shafts as in the case of the *King Edward*, *Amethyst*, &c.

Some greater economy might be attained both in weights of the turbines, and in steam consumption, by having instead of two high pressure turbines, a high pressure and an intermediate, exhausting into two low pressure turbines as before; but the advantage thus gained is partly counterbalanced by the loss of complete independence of the two sets of engines, most necessary for manœuvring, and the complication in the pipe arrangement. However, such arrangements are likely to be adopted in many cases in the near future.

During the past twelve years, there has been a distinct improvement in the steam consumption of turbine ships.

In 1897 the *Turbinia*	consumed	16lbs.	per shaft h.p.
In 1901 the *King Edward*	,,	16lbs.	,,
In 1907 the *Lusitania*	,,	12lbs.	,,
In 1907 the *Mauretania*	,,	11½lbs.	,,

The last figure represents about 69 per cent. of the energy available in the steam, according to Rankine's Cycle, and it is worth considering both where the increase in economy has taken place, and what increase is possible in the future.

Part of the improvement is due to increased size, which as a rule under similar conditions, gives more economy, because of the reduction in the ratio of clearance to length of blade, an

consequent reduction of leakage. Part also has been due to improvements in manufacture and design, especially in the direction of better vacua. Increase in the steam pressure above, say 120 to 150 lbs. at the turbines, as a rule, improves the efficiency of the turbine only a little, and adds to the weight not only of the turbine, but also the boilers, steam pipes, &c. More can be done at the lower end of the range of expansion, that is, by improving the vacuum. In the first lecture, it was shown that between a vacuum of 25″ and 26″ or between 26″ and 27″ (barometer, 30 inches) there was a gain of about 4 per cent., between 27″ and 28″ 5 per cent., and between 28″ and 29″ 6 to 7 per cent., or that about 3° Fahr. difference in the condenser temperature, meant a gain of 1 per cent. In the improved condensers described before, the temperature difference between the water leaving the condenser and the steam may be as low as 5° or 6° Fahr., and this with such high rates of condensation as 12 to 14 lbs. per square foot; and it is in the direction of more generally adopting such types of condenser as give the highest vacuum that one source of extra economy is to be looked for.

Another direction is the introduction of superheated steam for marine work as well as land work, but here the practical difficulties have not up to the present been satisfactorily surmounted. It is, however, quite possible that with improved arrangements and materials these difficulties may be got over in the future.

The application of the steam turbine to the propulsion of slow-speed ships, that is, ships of below 15 to 18 knots, has up to the present been difficult owing to the low speed of revolution of the screws making the turbines large and heavy, as well as not economical. This difficulty has now been got over by the use of an arrangement patented by Mr. Parsons some years ago, viz., the combination of reciprocating engines and exhaust turbines, similar to what was described before for land work. Here each utilises the part of the expansion for which it is best suited—the reciprocating engine for the high pressure part of the range, and the turbine for the low pressure where the volume of steam is large. The reciprocating engine, as explained before, is not economical for low pressures and large volumes, and the steam turbine, especially when the rate of revolution is small, is large, heavy, and uneconomical for high pressures and small volumes; but the turbine for low pressures, even at low revolutions, is an exceedingly economical heat engine. Thus the combination is more economical than either alone.

Many arrangements are possible, but probably the best is to have twin reciprocating engines port and starboard as in an ordinary twin screw ship, both exhausting at somewhere about 9 or 10 lbs. absolute into a turbine, driving a centre shaft. Under these conditions, the power in each shaft is about equal, and for manœuvring, the reciprocating engines alone are used, just as in the ordinary three-shaft turbine arrangement the low pressure turbines are used.

The first ship to be fitted thus is the *Otaki*, built and engined by Messrs. Denny, who are again taking the lead, as they did in the case of the *King Edward*. She is of 8,000 tons displacement, and at 13 knots sea speed requires only 5,000 horse-power. With 200 lbs. pressure and without superheaters being fitted, the very low consumption of 12·3 lbs. steam per shaft horse-power for all purposes was attained on trials, and better results are expected after more experience is gained in the working of the ship. But even this trial consumption is better than that which could be attained by the use of either reciprocating engines or turbines alone.

It is interesting to note that in the early days of the screw propeller the great difficulty was to make the engines run fast enough for the screw, and spur gearing was adopted in many cases in the first half of the last century. Gearing has been entirely dropped for the last fifty or sixty years, but now the difficulty in many cases is to make the turbine run slow enough for the screw, and once more gearing is being considered so as to make the turbine adaptable for use in slow speed steamers which, after all, constitute by far the greater part of the shipping of the world.

The combination system described above does this, but gearing a high speed turbine to a slow speed screw would also accomplish what is needed.

Eighty years ago, there was nothing but primitive spur gearing, with generally wooden teeth in one member, but now we have steel gears accurately cut by modern machinery, often with helical teeth, and running in oil baths. Chain gears of some form are also promising, as well as various forms of electrical and hydraulic gear. The electrical gearing is especially promising, one or more turbines with dynamos or alternators, practically identical with those used on land, being employed to

drive one or more motors on the screw shafts at reduced speeds of revolution. Again, in the combination system of reciprocating engine and turbine, the exhaust turbine may be a high speed one, driving a motor on the shaft of the reciprocating engine instead of a screw on its own shaft.

Such questions are now receiving much attention, and may result in all the steamships of the world being wholly or partly turbine-driven, instead of only those vessels of comparatively high speed.

At the present date there are about 120 vessels actually on service fitted with turbines, representing about 1,250,000 horse-power, and these comprise practically all the high-speed ships which have been recently built. Some 70 more are under construction, representing another 1,000,000 horse-power, or a total of 2,250,000 horse-power, and the curve of progress as yet shows no sign of saturation.

And now I have given you a short review of the position of the steam turbine at present. What the future may bring forth it is difficult to say. It has taken 200 years to bring the reciprocating engine to its present high state of efficiency; the steam turbine in a practical form is only 25 years old, and already has in many instances proved its superiority to its older rival. What may be the motive power of the future it is difficult to say. At present coal and waterfalls are the two great sources of motive power in the world; a minor one is the force of the wind, but largely on account of its uncertainty it is only of small importance. Another is the heat of the sun, but the utilisation of this directly has not been made practical as yet. But it is from this heat of the sun that we derive the power in our coal; in fact, the energy of the coal is the power of bottled sunlight which shone thousands of years ago, and there is more truth than is generally thought in Dean Swift's idea in "Gulliver's Travels" of the Laputans bottling sunlight in cucumbers. This electric light above us is really the sunlight which fell on the forests of the coal period many thousands of years ago. In this country we have little water-power. But the process of using coal to produce steam, and this steam to drive an engine, is a very wasteful one. In the very best steam engines only about 12 per cent. of the energy of the coalis converted into work, the other 88 per cent. is wasted in the losses in the chimney, by radiation, from friction, and, above all, in the condenser. This last is inevitable, owing to what is known as the second law of thermo-dynamics: it would take too long to-night to explain how it is inevitable. Slightly greater efficiency can be obtained by gas engines, but up to the present practical difficulties have prevented their adoption on a large scale. One way to get over this difficulty would be to form a battery using coal instead of zinc, and to convert the energy of the coal directly into electricity without the intervention of boilers, steam engines, and dynamos. How to do this has, however, still to be determined. But, as pointed out by the late Professor George Fitzgerald, there is a great source of energy in the air around us, if we could only tap it, and turn it to the use of man. This could be done by the "Sorting Demon" pictured by Clerk Maxwell. The second law of thermo-dynamics is only true for masses of molecules, and it may be possible that in the future we may find some way of harnessing the quick-moving molecules of the air, and letting the slow-moving ones go by. If we found out some such apparatus, we should be able to utilise for the service of man the energy of the atmosphere without the consumption of coal or other fuel. And if we look back on the advance made in the last 100 years, who will say it is impossible? Fancy our great grandparents in the "Flying Scotchman" travelling at the rate of 60 miles an hour. What would they think when a telephone was put to their ears, or a gramophone was set going? What would be the effect on a stage coach if it met a bicycle or a motor car? Still more, if an aeroplane arrived? Some of these things would have been declared impossible even within the memory of many of those here present.

SOME SPECIAL FEATURES OF THE DANISH SYSTEM OF CATTLE BREEDING.*

Denmark, mainly an agricultural country which formerly grew corn for export and raised very few cattle, began to turn its attention to dairy farming after the middle of last century. With the introduction of the centrifugal cream-separator and the building of co-operative dairy factories all over the country in the eighties the system of dairy farming spread to even the smallest farms. The question of improving the two national milking breeds, the black and white Jutland and the red Danish dairy cattle, became important and of interest to almost all farmers.

* Abstract of a paper read by Peter A. Mörkeberg before the Agricultural Sub-Section of the British Association, at Winnipeg, 1909.

The work of improving cattle breeding in Denmark being, as explained, of fairly recent date, has been gradually developed in two quite distinct directions; some features of the work aim at encouraging prominent breeders to develop herds capable of transmitting the most valuable qualities of the breed and inducing other breeders to take up this work, while other features aim at the better utilisation of the breeding animals from these superior herds for the improvement of the cattle breeding in general.

For the first purpose cattle shows and "selection of breeding centres" have been found useful, while Cattle Breeders Associations and Control Unions have helped in the other direction.

Cattle shows began about the middle of last century. At first all breeds and crosses competed together; from the sixties there were separate classes for the different breeds.

Already about the year 1870 the classes for single cows were discontinued and prizes offered instead for collections of cows bred by the exhibitor, a feature which is still considered very important, the idea being to draw attention to the best herds, which can more safely be done when a collection and not a single individual is shown. In 1887 the State caused to be held special shows for bulls over three years old for the purpose of encouraging farmers to keep the good bulls for a longer time. The result has been striking, the number of old bulls shown having increased from 371 to over 1,200. A special Danish feature has been introduced with these shows, viz., judging the bulls through their offspring, inasmuch as no prize is awarded for bulls over five years old unless their offspring, which must be judged before the show, have been found satisfactory. This entails a good deal of work, but has been found very useful.

The judges at shows take into consideration not only the points of the exhibited animal but also, in the case of bulls, the pedigree, including information of the milk production of the dam, and in the case of cows the milk production (quantity and quality).

Selection of breeding centres, that is a systematic selection of the best herds, which then receive an official recognition as "Breeding Centres," is another special Danish feature introduced in 1894. The herds are entered for a competition which is carried on during two whole years by a committee of judges, who visit the herds on the farms five or six times, while assistants on every twentieth day during the two years visit each of the competing herds, weigh the milk of each cow, test its percentage of fat, weigh the fodder given to each cow, and draw up the family herd book, in which the whole herd is arranged according to maternal descent, each animal being described with its sire and dam, milk production and prizes. At the end of two years' testing the committee of judges have acquired reliable information as to the value for use and for breeding of the different herds. The best herds are then designated as "Breeding Centres," with the result that the demand is increased for breeding animals from these herds at enhanced prices. A full report of the result of the two years' competition is published.

The Cattle Breeders' Associations have for their principal aim the purchase of a good bull. The first Association was formed in 1883. From the first these Associations paid attention also to the cows and to the health of the herds; they required also accounts kept of the feeding and the yield of the individual cows. From 1887 the State gave a yearly grant which helped the movement on. There are now 1,300 Cattle Breeders' Associations with 1,500 bulls, the State giving £8 per annum per bull on condition that the bulls have taken prizes, that the committee select the best cows of the members to be served by the bull, and that the committee at least once a year inspect the herds on the farms as to the state of health.

While the other objects of the Cattle Breeders' Association have been attained it was different with the required accounts of the feeding and yield of the individual cows. The members could not manage these, and when in the beginning of the nineties information of the percentage of fat in the milk was included in the requirements it was found necessary to take this whole matter up in a different way. This led to the formation of the Control Union of Cow Testing Associations. The object of these is to strike a balance-sheet for each individual cow for the guidance of the daily feeding, for the weeding out of those cows which it does not pay to keep, and for the selection of cows for breeding. Farmers in a district appoint jointly a "controlling assistant," who once every fourteen or twenty days visits each herd, weighs the milk of each cow, estimates the percentage of fat, weighs the food given daily to each cow, and keeps account of it all. He further keeps a book of the serving and calving, with all information necessary for the family herd book. The first Control Union was formed in 1895; now there are 479, with 10,925 members and 187,345 cows, comprising over 17 per cent. of the total number of cows in the kingdom. The work is carried on by 500 controlling assistants, the State giving a grant of £14 per union yearly.

The information with regard to the yield and quality of milk of the individual cows collected by the Control Unions is taken into account in awarding the prizes at the shows, and is also made use of in selecting the cows to be served by the bulls of the Cattle Breeders' Associations.

THE LUNACY REPORT.

The report of the Commissioners in Lunacy, just issued, shows that the figures for lunacy continue to rise somewhat rapidly. The last ten years show an increase in the general population of 12·1 per cent.,

while the insane have increased 22·5 per cent. On January 1, 1909, there were known to be under care in England and Wales 128,787 persons certified as insane, a number which exceeds by 2,703 that recorded on the 1st January, 1908. The average annual increase for the ten years ended December 31, 1908, was 2,370, and that for the five years ended on the same date 2,317; or, to put it in another way, on the 1st January, 1909, the total number of notified insane persons in England and Wales stood to the estimated population in the proportion of 1 to 278, or 36·02 per 10,000. This gives an increase on the ratio of the preceding year of 0·98 per cent., whilst the actual numerical increase has been 2·1 per cent. On the 1st January, 1899, this ratio was 32·96, so that in the ten years it has increased by 9·2 per cent., the proportion of such insane persons, in the community having risen from 1 to 303 to 1 to 278. No doubt, increasing thoroughness of notification has something to do with the increase. Influenza too, a comparatively new scourge, has played its part, more especially if it has induced any large proportion of the heart troubles by which mental defect is so often accompanied. Urban life, with its temptations and strains on the nervous system, accounts too for a part of the increase, and drink, which is not one of the largest factors in female lunacy, accounts for 24 per cent. of the male pauper lunatics. The increases in lunacy show a decided tendency to be in urban rather than rural counties, and in the larger rather than the smaller boroughs, Manchester heading the list in this respect. There also appears to be a high ratio of insanity in nearly all the professions (except that of teachers) where the work is mental. For example, the ratio for clergymen is 10·7, medical practitioners 14·2, literary and scientific persons 19·4; civil and mining engineers 49·8; artists, engravers and sculptors 25·4; architects 23·2.

For many years past the Commissioners have, at intervals, indicated the great importance they attach to the early and individualised treatment of insanity as affording prospects of recovery with which the results of subsequent efforts are quite unable to compare, and it is possible that many people lose their reason who would not do so if they could be detained and appropriately treated at an earlier stage of their affliction. The Commissioners urge the need for the removal of some of the difficulties which attend certification and which, as they say, lead to constant infractions or evasions of the law, and to such delay in treatment as is frequently disastrous. They recommend that if a medical practioner certified that a person was suffering from mental disease, but that the disease was not confirmed, and that it was expedient with a view to his recovery that he should be placed under the care of a person whose name and address should be stated in the certificate for a period therein specified not exceeding six months, then during that period the provisions of Section 315 of the Lunacy Act, 1890 (which makes it illegal to receive or detain a lunatic, or alleged lunatic, in an institution, or in an unlicensed house, except under the provisions of the Act and the order of a judicial authority) should not apply. The Commissioners support their recommendation by the example of Scotland, where the treatment of incipient insanity, in the manner they suggest, is lawful, and works as well, but it may be expected that Parliament will examine very narrowly any proposals that might have the effect of lessening the safeguards against improper arrest and detention. The Commissioners support the far-reaching proposals submitted a year ago by the Royal Commission on the feeble-minded. It may be remembered that they relate to a better and fuller classification of cases; the extension of treatment to kinds of mental defect at present unduly neglected, and the withdrawal of the whole matter from the Poor-law authorities, which means, practically, the abolition of "pauper lunatics."

THE USE OF CAMELS FOR TRANSPORT IN TURKEY.

There is no scientific system of camel breeding in Smyrna, and now they are only to be found in the villages of the ancient nomads or Yuruks, who are numerous in every part of the country. The nomads make a living for the most part in transporting merchandise from one part of the country to another where there are no railway communications. The dromedary is the chief beast of burden, but, for some unexplained reason, the number is diminishing from year to year. The American Consul-General at Smyrna says that there exist at present three varieties of the dromedary. The first variety is distinguished by the long hair of the mane, and more especially by the length of the hair of the shoulders and neck in the winter time; the second has light curly hair on the mane, neck, and shoulders; the hair of the third is perfectly smooth, and this variety is chiefly found in the mountain districts of Asia Minor. These varieties are obtained from cross-breeding with the two-humped camel, which certain proprietors bring from the district of Konia and Angora every winter, and the females of the second and third varieties. The food of camels and dromedaries in the district of Smyrna, from the month of September to March, consists of straw and beans, which are moistened, pounded, and kneaded before being given to them each evening. From the month of March onwards, and during the extreme heat of the summer, they live chiefly on hay and grass. The Yuruks of the highland district plant grain and valonia acorns in fields where camels have pastured for a season. The prices of dromedaries are as follows:—First variety, £18 to £23; second variety, £14 to £18; third variety, £11 to £14. Dromedaries are used principally for transporting merchandise such as cereals, valonia, figs, emery stone, licorice root,

&c., and in this capacity they are indispensable. As many as a hundred are sometimes seen, led by a little donkey, each laden with the products of the interior of Asia Minor, and all bound for Smyrna, the nearest seaport. In Smyrna itself they are so numerous sometimes in the streets of the city that they block the traffic. In the rough mountain districts they are much more useful than horses and donkeys, especially in many districts where there are no country roads, while, at the same time, they can carry much greater loads to market. Then, again, the cost of maintenance is very much less than that of any other beast of burden. The third variety is especially adapted for hilly country, and this is one reason, perhaps, why only this breed is to be found among the villages situated in the mountains. At the age of three they are broken to loads, but it is only at the age of five or six that they can do the maximum of the work devolving upon them. The strength ol a camel begins to decline at the age of twenty, as the average life of the toughest breed is only about twenty-five years. The best species come from the villages situated in the plains, and those of the Meander Valley are preferred to those of the Hermus. The cost of maintenance depends a good deal upon the liberality of the proprietors. Among the Yuruks, who inhabit the high mountain districts, their keep amounts to practically nothing. The cost of keeping a camel, however, in the Menemen plain, near Smyrna—during the winter months only—that is about four months' stabling, may be estimated at £5. The ordinary caravans consist usually of seven camels, and experience has shown that this is all that can be conveniently entrusted to one driver. The price for transportation varies according to the locality and the amount of work, but the average cost of a camel will come to about two shillings a day. In Smyrna, one Turkish merchant owns about 400 camels. Throughout Asia Minor, camels or dromedaries are used only as beasts of burden, while in Syria many are broken to the saddle and used as riding animals across the deserts. Upon the great caravan route between Trebizond, on the shores of the Black Sea, and Tabriz, in the heart of Persia, hundreds of loaded camels in a single drove may sometimes be seen. While, as time passes, the camel will not be able to stand the keen competition of the new railways, which are piercing every part of Asia Minor, yet, thanks to the power of tradition over the Turkish inhabitants of the country and the fondness for these animals, the caravan routes of to-day are still able to hold their own side by side with the Anatolia, Cassaba, and Aidin railways. Hundreds of camels pass over the caravan bridge into the city of Smyrna every day, and in the market place in front of the mosque of Mohammed, at Constantinople, many camels may still be seen. As far back as the middle of last century, General Von Moltke, in his descriptive letters from Asia Minor, had many good words to say about the camel. "This animal," he said, "can carry a burden of nearly six hundred pounds, and is used by the nomads and Arabs in taking their women, children, old men, tents, food, water, &c., from place to place. It is able to withstand a march of ten days without drink. The hair of the camel is used for clothing and tents. The milk and flesh are healthy. It exists on the most miserable food, such as grass and thistles. Such are the characteristics of this patient, strong, and most useful of animals." A camel is never relieved of its load from the beginning of the journey to the end. It eats, walks, and sleeps under its burden, often for weeks at a time. The training of a camel is no easy matter, as it takes about three years to teach it to bend the knees in order to be loaded and unloaded.

THE DEVELOPMENT OF SICILY.

The future of Messina is still a matter of uncertainty, according to the new Consular Report on Sicily, but circumstances make it probable that in a few years it will regain its former importance, though for the time being there will be a tendency for the trade of the eastern side of the island to diverge to Catania and Syracuse. From the point of view of the inhabitants of Palermo it would be very disastrous if the extinction of Messina were of long duration, owing to the connection and close communications that have so long subsisted between the two cities. Arrangements had been made for the construction in the earlier part of the year 1908 of two large and improved ferry-boats between Messina and Reggio di Calabria on the mainland. The main object of these new boats was to permit of a *train de luxe* crossing the Straits on one boat instead of on two, with the consequent division of the train into two portions, as heretofore. The new boats were designed to attain a speed of thirteen miles an hour; they were to be built at Naples and Leghorn, and to cost £80,000, but the calamitous consequences of the earthquake have ruined these and other projected improvements. Another enterprise which appears to have been suspended or postponed, if not actually put an end to, was the inauguration in January last of a fast service from Messina to Egypt by means of well-appointed steamers of 12,000 tons. The voyage from Messina to Alexandria was to have occupied only forty hours. Although there were numerous openings for British trade with Messina, especially in tissues, such as woollen, muslin, cotton goods and apparel, implements, boots, &c., it is surprising to read that only one commercial traveller called at the British Vice-Consulate during 1908. The most important British import into Sicily is coal, of which 642,185 tons were conveyed thither in 1908, this being a considerable increase on the figures of the previous year. Among the more important exports from Sicily it is worth noting that the check sustained by the sulphur industry in 1906, owing to vigorous competition by

American produced sulphur, continued in 1907 and 1908. The exports are believed to have diminished, and there is without doubt an accumulation of stocks and over-production, into which a Government Commission is at present inquiring. Wine, another interesting Sicilian product, has commanded very low prices, as much of the 1907 wine was still unsold at the time of the vintage. Nevertheless the yield in 1908 was above the average. It would have been still larger had the year not been exceptionally dry, but the absence of rain during the vintage and the comparative coolness of the summer, combined to produce a wine of very good quality and of greater alcoholic strength.

ARTS AND CRAFTS.

The Lace Exhibition at the Mansion House.—Lovers of hand-made lace had a real treat last year in the Exhibition held at the Horticultural Hall. The little show at the Mansion House last week was, of course, on a much smaller scale, and a good many of the exhibitors complained of the limited space at their disposal; but quite enough was shewn to prove the vitality of the hand-made lace industry in this country. Moreover, the leaflets circulated in the Exhibition by the newly-formed "National Association for the Organisation of the Hand-made Lace Industry in England" made it plain that those interested in the maintenance of English lace-making and the well-being, both of the industry and of the workers, are combining in the hope of improving the quality alike of design and workmanship.

In the desire to give employment to people in country villages and to dispose of the lace made by them, a certain amount of work has been encouraged which is by no means as good as it ought to be. The more far-sighted of those in the revival and the continuance of lace-making in this country realise that the prosperity of their industry, and of the workers engaged in it, will be furthered, not by doing cheap lace, which might almost as well be turned out by the machine, but by encouraging the competent execution of good designs. In lace-making, as in other trades, it is the really skilled worker in the finer kinds of work who earns the best wages. It is also the fine lace, which no machine can successfully imitate, which can count on a steady market at a good price; and good workmanship is wasted upon a worthless design. It is, therefore, to be hoped that the effort to raise the level of taste and technique will meet with that success which it certainly deserves.

The general standard at the Mansion House was high. There was some coarse lace made on the lines of Italian and Austrian work which was very pleasing in effect, and some of the Buckingham lace was very good. But the most interesting exhibits, on the whole, were those from Devonshire. The little case of work exhibited by students of classes held under the Devon County Council included one very fine specimen of Honiton, and several other pieces which as the work of pupils who had only been under tuition for fifteen months and did not come from districts with a strong lace-making tradition, were quite remarkable. The people responsible for the North Devon Cottage Industry have had the happy thought of going back behind the regular Honiton tradition, and reviving the older Devonshire lace with its more conventional design and somewhat different treatment. The majority of the lace designs sent in were rather disappointing. Some were eminently fit for their purpose and others were quite satisfactory as patterns, but they were seldom good in both respects.

The Schools.—It has become the custom in the London Art Schools to hold an exhibition of students' work just before the beginning of the school year, which opens with the autumn session. At the large schools these shows are, of course, confined to the work of present pupils, while at the smaller ones a considerable space is sometimes allotted to the work of former students now earning, or trying to earn, their living by their skill. It is, not unnaturally, somewhat of a disappointment, after going carefully through the National Competition show, where the exhibits are not merely the pick of the work sent from the schools all over the country, but the pick of that, to turn to the productions of the local schools one by one and to see how very much higher is the level of accomplishment required for success in National Competition than the attainments of the ordinary average student. Indeed it is difficult to get the higher standard out of one's head and to judge the work of the individual schools quite fairly. For all that these smaller and less attractive shows fulfil a very useful purpose and ought to be of the greatest interest to the student. Nothing is easier to the would-be student than to go round an exhibition of works gaining awards in National Competition and to imagine that in a year or two's time he will inevitably, since of course he is a very clever fellow, be doing work as good as what he sees there. If, however, after his visit to South Kensington, he goes to see the exhibition at a local school of art he will realize, unless he is singularly wanting in intelligence or suffers from inordinate self-satisfaction, that it is by no means so easy as he fondly imagined to do really good work as a designer and a craftsman, and that there are a very large number of serious students who never arrive at doing anything like first-class work. No one wants to depress students unduly at the beginning of their career, but they are far more likely to be permanently depressed if they start with the idea that they are going to do wonders than if their ambitions at the outset are more modest.

Some Recent Lustre Pottery.—It is not at all surprising that in a scientific age some of the most successful artistic achievements should be in crafts and manufactures where chemical experiment plays a very important part. Artists and men of science do not always understand each other very well; but the

man of science whose researches enable him to produce something really beautiful is, they must admit, a very good friend to art. The branch of industry in which art and science have of late years walked most peacefully hand in hand is perhaps pottery manufacture. It cannot, of course, be contended that any very large proportion of the output of the pottery trade in this or any other country is really artistic; but there is no doubt that the direct outcome of increased chemical knowledge has been the production of beautiful wares, some of which, like the various types of crystalline glazes, are really new, whilst others, like lustre, are the revival of an art that was long lost. The sort of boom in crystalline glazes which followed the last Paris Exhibition seems for the moment to have come to an end. It appealed apparently only to a very limited public. There is, indeed, some very charming work being done in these kinds of glazes, but the attention of manufacturers seems just now to be directed rather towards lustre. There are several firms making lustre ware of various kinds, but the exhibit of the Pilkington Tile and Pottery Company at the Franco-British Exhibition last year, which included a large show of painted lustre, marked a very definite step forward in the development of lustre painting. It is one thing to get lustrous effects of one sort or another; it is a very different and much more uncommon achievement to paint in lustre patterns and figures which, with all the wealth of ever-changing colour, are clearly and precisely drawn. It is therefore very interesting to see that, instead of resting content with what was accomplished last year, the firm has been still further developing this kind of work. Not only have they increased their range of colours—some of the deep strong blues now being made are really fine, and the delicacy and brightness of the newest green is quite wonderful—but they have had, further, the happy idea of painting a thin coat of slip under the glaze which strangely changes the whole quality of the colour. Sometimes the inner surface of a bowl is completely coated with slip while the outer surface is glazed in the ordinary way, and this results in a very pleasing contrast of effect. An equally pleasant contrast on the outer surface of a vessel is obtained by coating only the neck or some prominent portion of the ornament. The under-coating of slip, without taking from the lustrous effect, adds considerably to its delicacy, and it produces always a very subtle variety in the quality of the colour.

In the direction of modelling in combination with lustre a good deal has been done in the last year. One of the largest recent pots is enriched with a St. George and the Dragon in comparatively high relief, whilst some of the vases have bulbous necks decorated with modelled ornament, and higher relief than heretofore is used in some of the tiles. It is, no doubt, very easy to overdo relief in pottery. If the artist does not exercise a good deal of self-restraint, his work may get lumpy and coarse before he is aware of it, but of the suitability of a modelled surface to the display of lustre colour there can be no manner of doubt. For one thing the glaze, melting as it does in the fire, runs off the parts in high relief and collects in little pools, as it were, in the background, which leads to an astonishing variation in the depth of the colour. Then, the unevenness of the surface, which catches the light at all sorts of angles, not only enhances the effect of the lustre, but adds greatly to the variety of its tone. There may be room for objection to modelling on vases on the ground that, modest as it may be in its early stages, it will probably end in excess; but the objection could hardly be urged by the most bigoted critic with regard to tiles, whilst it would be difficult to imagine more beautful colour than that produced by the play of the firelight on modelled lustre tiles.

EMPIRE NOTES.

Steel Smelting in Vancouver.—A striking illustration of the need of alertness on the part of British capitalists is afforded by the statement that a United States firm—the Irondale Steel Company, of Washington—proposes to locate on a site to be selected somewhere in the Province of British Columbia a plant which will employ not less than 1,500 men. The company looks for a subsidy from the Government of the Province which is likely to be granted, as, according to Mr. A. T. Frampton, who writes from Victoria, British Columbia, there is an exceptional opportunity for the establishment of an industry of this character in Vancouver Island where iron ore, coke, and the necessary fluxes are obtainable. He says that the authorities of Victoria have done their best to point out the unique advantages likely to attend the starting of an industrial enterprise of this nature, and have in vain sought to obtain the support of capitalists from the Mother Country for the purpose. Now the opportunity will be lost to them to the profit of our American cousins.

The Powell Wood-Process in New Zealand.—This wood seasoning process which consists of boiling timber in a saccharine solution, and then passing it into specially constructed drying chambers is about to be installed at Raugatana in New Zealand. The inventor of the process is Mr. William Powell, formerly of Liverpool, who, some years ago, noticing that timber used for flooring or wall plates in sugar factories never appeared to be affected by dry rot, made a number of experiments, which led him to conclude that wood boiled in a solution of molasses and water, and carefully kiln-dried afterwards, could be seasoned rapidly without splitting or cracking, and, with the addition of other ingredients, might be rendered immune to the action not only of dry rot but of white ants and the teredo, or sea worm. The process does not appear, at present, to have "caught on" in England, but in Australia and India works have been installed, and now the New Zealand timber people

have taken up the matter. As there appears to be value in the process it is surprising that it has not been adopted for rapid seasoning, and for rendering timber immune against dry rot, in this country.

The Federalisation of Australian State Debts.—This important proposal, which had been decided upon by the Prime Minister of the Commonwealth and the Premiers of the various States, at their recent conference in Hobart, has been submitted in the form of a Bill to the Commonwealth Parliament. The Bill provides for a Referendum on the subject, which will probably be submitted to the electors at the Federal elections in March next. The present State debts amount to £247,974,624. To this amount a few millions will have to be added, to cover financial obligations incurred since June 30th, 1908, bringing the total up to about £250,000,000 sterling. While this proposal will not interfere with the rights of the States or the municipalities to borrow on such security as they can offer, for railway construction and other reproductive and public works, some restrictions will, no doubt, be imposed as to the amount of such loans. It is, however, confidently expected that a considerable saving will be effected in the way of interest, which at present entails an annual charge of £8,839,695 upon the various States. This, one of the most important steps towards federation which has been taken by the Commonwealth and States Governments, should not only be to the commercial and financial advantage of the Commonwealth, but should lead to greater unity of action in all federal matters.

Trade Movements in South Africa.—Official statistics from Natal show that instead of an anticipated deficit there has been for 1908 a small surplus, which, in view of the recent lean years, is regarded as a favourable sign of improving financial conditions. The shipping returns are nearly up to those of the best shipping year (1905). The imports and exports, however, show a reduction, but there has been a considerable increase in land under cultivation and in the stock held by farmers. In the Transvaal, the revenue shows a large increase upon the previous year, while the amount of trade in tonnage, according to the report of the Chairman of the Board of Trade at Johannesburg, has increased in round numbers 9,000 tons a month during the six months ending June 30th of this year, as against 8,000 tons in the previous six months. There was also a satisfactory increase in the tonnage of goods in the Orange River Colony, while the imports in the Transvaal had increased to the amount of a million sterling, and the exports to over £700,000.

Gold Mining in Victoria.—The reduction of the cost of cyaniding from 10s. or 12s. per ton to 2s. opens a wide field for treating the low grade bodies of quartz and the alluvial sediments in Victoria. In a report of the State Director of Geology, he says that, in the stilt or tailings of the gold ore treated in Victoria, there is as much impalpably fine gold left as all the alluvial gold hitherto won. This is a striking statement in view of the fact that since the gold discovery of 1851, Victoria has produced over 66 million ounces, of the value of more than 282 millions sterling. There is no doubt, however, that the application of this process on a large scale will yield immense results in all the gold fields of Australasia. There are numbers of low grade mines in Western Australia, for example, which might be made to yield considerable returns were sufficient capital forthcoming to apply the economic methods of treatment now in vogue, notwithstanding the difficulties arising from the scarcity of water in the dry areas in which they are located. Here again is a great opening for the profitable investment of British capital.

Military Pensioners and Emigration.—In two recent articles in the *Pall Mall Gazette* the subject of the suitability of military men for emigration and of the opportunity afforded to pensioned non-commissioned officers to commute a considerable part of their pensions for this purpose, has been very ably treated. For purposes of defence as well as settlement it seems very desirable that many ex-soldiers, who, at present, find it difficult, if not impossible, to obtain work in England, should be encouraged to emigrate to the oversea dominions of the Crown, where they and their families might find new homes under conditions far more favourable than are possible here. According to these articles, a movement is on foot to get the War Department to extend the concession of commutation to private soldiers whose pensions only average 1s. or 1s. 1d. per day. At present, the Army Regulations require pensioners to leave 1s. at least of their pension uncommuted, which debars thousands of men, many of whom would gladly avail themselves of the opportunity of settling in our Colonies, from securing even a partial commutation of their pensions. Attention is also drawn to the fact that the Government scale of commutation is lower than the commercial value of such pensions; a fact which requires attention if we desire to do justice to men who deserve well of their country and who, in re-entering civil life, should be afforded every facility to make a good start for themselves and their families.

Colonial Exhibitions and their Uses.—In the address of Mr. Justice Longley at the inauguration of the Provincial Exhibition in Halifax, Nova Scotia, he claimed that that Exhibition had had "an immensely stimulating influence upon the agricultural and industrial life of the province." The Exhibition was designed to demonstrate the great variety of the resources of Novia Scotia—agricultural, horticultural, mining, and fishing—and its object appears to have been realised. Special mention is made of the display of fruit which was much commended, and of the root, and green crops which were far ahead of previous

years. There is no doubt that such Exhibitions help to awaken local interest and to arouse a spirit of emulation, especially among exhibitors of agricultural produce, which must make for the good of the country. At the same time, in the interests of our home trade, it is most desirable that the British manufacturer should be well represented at Exhibitions of this character held in the leading industrial and commercial centres of our Empire.

CORRESPONDENCE.

EARLY STEAM NAVIGATION.

In the note in last week's *Journal* on Early Steam Navigation, it was stated that Henry Bell obtained information *from* Fulton, but that no authority was given by Galloway for the statement. "From" is a misprint for "for." The authority for this statement is to be found in a letter by Bell, addressed to *The Caledonian Mercury* in 1816, and quoted by Woodcroft. From this it appears that Fulton had requested Bell to call on Miller, and obtain a drawing and description of his boat. This he did, and Bell adds that two years later (which would presumably be about 1790 or a little later) he heard from Fulton that he had constructed a steamboat, which seemed likely to answer, but required improvement. Bell goes on to remark that his correspondence with Fulton led him to think that it was absurd for him to send information abroad, and not to put his knowledge into practice in his own country, and it was this consideration which induced him to set about the construction of the *Comet*. Fulton therefore had a share in the introduction of steam navigation in Europe as well as in America.

After this Fulton came over to England, and in 1801 he was present at some of Symington's experiments, and was actually carried for some distance in the *Charlotte Dundas*. An objection made by Symington that the progress of the boat was impeded by the narrowness of the canal was answered by Fulton that the objection would not apply to the large rivers of North America, and this of course proved to be the case.

Mention ought perhaps to have been made last week of the Marquis de Jouffroy, who, in 1783, experimented with a boat at Lyons in which motion was communicated from a steam-engine by ratchet gear to a paddle-wheel. This was probably the first vessel ever moved on the water by steam.

GENERAL NOTES.

WOMEN MEMBERS OF THE SOCIETY.—It may be interesting to note that ever since the foundation of the Society there have been some lady members. The earliest list in the possession of the Society (1756) contains the names of two ladies—Lady Betty Germain and Miss Elizabeth Vaughan. The Countess of Denbigh's name is added in 1758, and those of the Countesses of Macclesfield and Northumberland in 1764. Since that early date there have been very many women members, and their number is now considerable.

THE MALAGA RAISIN INDUSTRY.—In his report on the trade of Malaga, just issued, Mr. Cecil Staniforth directs attention to the export trade in raisins, and makes some remarks to which the attention of buyers in this country may be usefully directed. Owing to the low price which continued throughout the last vintage, farmers generally complained bitterly, so much so in fact that many who had large tracts of land in the best situations in the Guadalhorce Valley (which yields the best quality of fruit for the British market) have decided that their interests will be better served by planting beetroot, and are going to uproot their fine old muscatel vines. The root of the evil, says the Consul, lies in the fact that the principal markets of the United Kingdom refrain from buying at the commencement of each season, thus forcing the poorer farmers to send their fruit on consignment to London, and when once this market holds large stocks, the fruit is sold by auction at disastrous prices for the local farmer. There is every indication that if this course of events is annually repeated the Malaga raisin industry will, before many years, become a thing of the past. The total yield last year was about 900,000 boxes, or about a quarter more than was expected.

OPIUM IN CHINA.—It will be remembered that the Indian Government, in pursuance of its declared intentions, has been reducing the amount of opium offered for sale in India by about 5,000 chests annually, so that the amount put up for auction in 1909 will be 43,200 chests instead of 52,800 in 1907. But it may be gathered from Mr. O. R. Coates' report on the trade of Shanghai, just issued (Annual Series, No. 4360), that there has not been any appreciable decrease of native opium placed on the market. In fact, the amount of opium brought to Shanghai has been unusually large. In 1906 the gross amount of foreign opium imported into Shanghai was 33,219 cwt., and of native opium 15,731 cwt.; in 1908 the imports of foreign opium fell to 28,869 cwt., and the amount of native opium increased to 22,814 cwt. gross. A succession of Imperial decrees spurred the provincial governments to energetic efforts to suppress the opium habit, and among other measures the establishment of official monopolies for the sale of the drug, native and foreign, has been one of the most favoured. This form of restriction was obviously contrary to the treaties, and has been strenuously and successfully opposed by foreign dealers in the drug, but the attempt has had a disturbing effect on the trade, native dealers not daring to invest in large stocks of opium lest some arbitrary action of the local authorities should suddenly involve them in loss.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

AERIAL FLIGHT.

By F. W. Lanchester.

Lecture I.—Delivered April 26th, 1909.

The engineer, accustomed to dealing with problems in locomotion or traction, when confronted with the proposition of mechanical flight, will ask as his first question, "What is the magnitude of the coefficient of resistance, and on what factors does it depend?" In other words, "What is the force necessary to maintain a flying machine of given weight in a state of uniform horizontal motion?" It is only within the last few years that it has been possible to give an authoritative reply to this question, and even to-day we do not know with certainty what is the lowest obtainable limit. The coefficient of resistance or traction not only tells us what force is required to maintain a given body in motion, but as an immediate consequence it tells us the energy required to effect the transference of the body from one stated place to another stated place, since energy is force multiplied by distance, and, therefore, other things being equal, the coefficient of traction is the measure of the cost of traction.

In the first place a few facts will be given as to the resistance that obtains in other modes of locomotion, in comparison with that of some of the existing successful flying machines.

The resistance of an iron tyre over a common road varies ordinarily between 2 per cent. and 3½ per cent. of the load, depending upon the kind of road surface and its condition; the figure is much the same if solid india-rubber be substituted for the bare iron. If the pneumatic tyre is employed the tractive effort depends less upon the nature and condition of the road surface; it is usually about 2 per cent. to 2½ per cent. For a passenger train on rails the coefficient is commonly less than 1 per cent., being in some exceptional cases (at low and moderate speeds) as low as ·25 per cent. For ocean-going vessels the figures are much the same as for vehicles on rails. Thus the *Lucania* at full speed has a coefficient of ·7 per cent., and the figure for slow cargo vessels varies from about ·25 per cent. even down to ·1 per cent., the latter being the coefficient for a slow "tramp" steamer of large size.

Against the above figures the coefficient in the case of the Voisin flying machine is 13 per cent. or 14 per cent., and for the Wright machine 12 per cent. or thereabouts; thus in flight, if we may judge by existing practice, the resistance is at least four times as great as in any commercially established mode of locomotion, and is 20 or 30 times as great (or even more) as in transport by rail. These figures are given concisely in Table I, p. 1006.

It is evident from the foregoing that the power required to drive a flying machine at any given speed is far in excess of that required in any "commercial" mode of locomotion, and may be roughly represented as equivalent to driving an automobile up a gradient of at least 1 in 10. In view of the fact that for divers reasons (to be discussed later*) it is imperative that the velocity of flight should be at least in the neighbourhood of 30 or 40 miles per hour, it becomes evident that the problem of supplying the necessary horse-power is one of a very serious kind; in fact, it is *the* problem ever confronting the designer of the flying machine.

Professor Langley, of Washington, stated, some 18 years ago, that the power required for flight is less at high than at low speeds. This conclusion was given as a result of certain experiments, and it was for a considerable time very generally accepted, being termed

* Lecture II.

"Langley's law," though by what right it is not clear, since a law should be a quantitative and not a mere qualitative statement, and since the same view had already been expressed by Wenham.

Unfortunately, the optimistic view propounded by Langley in his so-called law has not been realised; in fact, it has no actual justification. It is founded on the supposed negligibility of skin-friction, a supposition that can be no longer upheld.

As a matter of fact, the power required for flight increases when the velocity is increased, and experiment and theory both indicate that the power and the velocity increase in approximately the same ratio. In the present lecture I propose to demonstrate the real relations that exist between power expenditure and velocity, and to point out the factors that impose a limit on the performance of the flying machine of the future.

In the first place let us turn our attention to the evidence of the hard facts with which we are acquainted. I have here a model, No. 1, of ½ gram weight, designed to fly at the very low velocity of five feet per second, and it will be observed that the gliding angle is approximately one in five, that is to say, the rate of descent is, roughly, one foot per second.

Now the work done by gravity in overcoming the resistance to flight is measured by this rate of descent, and since one horse-power is represented by the descent of a mass of 550 lbs. at one foot per second, the performance of this model is equivalent to a rate of 550 lbs. (sustained in flight) per horse-power expended. Putting this another way, if we had 550 lbs. weight of models identical with the present sample, they would require collectively a tow rope pull of 110 lbs. to maintain them in horizontal flight, which at five feet per second means 550 feet per pounds-second, or one horse-power.

Another model (No. 2) travelling at 17 feet per second, has a velocity of gliding descent of 2½ feet per second, which is the equivalent of 220 lbs. sustained per horse-power. These results are set out in Table II., p. 1006. The corresponding figures are given for the Voisin and Wright machines, due allowance being made for the approximate propeller efficiency in both cases.

It may be regarded as probable that the resistances and rate of power expenditure of the most successful flight machines of to-day, though not actually the best obtainable, will be sufficiently near the minimum for the purpose of approximate comparison.

The results are striking; they not only dispel at once any illusion on the subject of "Langley's" law — the power actually increases in an unmistakable manner with increased velocity—but when the figures are transformed to represent the coefficient of resistance they indicate that this quantity is, roughly speaking, constant. This latter is a really remarkable and important fact, the full significance of which will be appreciated later.

We will now pass to the theoretical aspect of the subject, and firstly we have to consider the laws that govern the pressure reaction experienced by planes and other bodies in motion in a fluid.

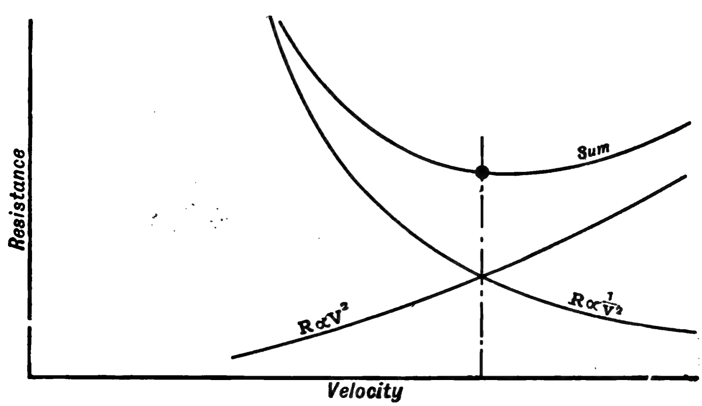
There is one law that, as a close approximation, is applicable to all cases of fluid resistance—between certain limits of velocity: this is the "V^2 law." It is expressed by saying that for a given body in stated presentation the fluid dynamic reaction, or the component of the fluid dynamic reaction in any specified direction, is proportioned to the square of the velocity. It is almost needless to remark that the rate of doing work in overcoming the line-of-flight component of the pressure reaction is equal to this component multiplied by the velocity, V; hence a corollary to the V-square law of resistance is that the power varies as V^3. This is by no means the correct law for the power expended in flight.

The question arises at once—If the V^2 law is a generalisation, why should it not apply to the case of a bird or machine in flight? The reason that the law of flight resistance is not the V^2 law, is that one of the pressure components, the vertical component, is defined: it is the weight of the body and is constant. There is a certain velocity at which the weight of any given bird propelled through the air would be just sustained; at velocities less than this there is a deficit in the sustaining force, at greater velocities there is an excess. Now if by some occult means the weight of a bird could be made to vary as the square of its velocity of flight, the V^2 law of resistance and the V^3 law of power expended would apply; but in the absence of such variation, that is to say, with $W =$ constant, the bird requires to alter the shape or angle of its wings so as to derive from the air just the necessary pressure reaction and no more, and this alteration of shape or angle gives rise to new conditions and laws of an altogether different kind.

Most of the experimental work on the present

subject has been done with planes, and not with curved forms as the wings of a bird, but these aeroplane experiments have furnished results of the right kind. In brief, it has been shown that if the surfaces were not subject to skin friction the resistance would become less when the velocity becomes greater according to an inverse square law; this law may be regarded as an approximation of a sufficiently exact kind for planes of any reasonable *aspect ratio* so long as the angle of incidence of the plane is small. If this law—the law of frictionless flight—actually held good, the power required would, as believed representing their sum. Now here a fact is apparent of which the proof is given in the author's work;* the total resistance has a minimum value at the point where the two different kinds of resistance are equal one to the other; thus, if an aeronaut requires to travel from one point to some other point on the least supply of fuel he will choose the velocity corresponding to this point of least resistance. If, on the other hand, an aeronaut desires to fly with the least possible expenditure of power he will require to fly at a lower velocity, for the horse-power, *i.e.*, rate of doing work, is proportional to the resistance multiplied by the

FIG. 1.



by Wenham and Langley, diminish as the speed increases; but this is far from being the case, for the tangential drag (or skin friction) is considerable; according to recent experiments the resistance of a thin plate moving edgeways is commonly between ·006 and ·020 of the resistance of the same plate moving normally, *i.e.*, at right angles to its surfaces. This ratio is expressed in the author's work, "Aerial Flight," by the symbol ξ, termed the coefficient of skin friction; it is the *double-surface* coefficient, and varies in approximate accordance with the V^2 law; hence the resistance due to the organs of flight consists of two parts which vary in an opposite manner with respect to variations of velocity.

In Fig. 1, in which abscissæ represent velocity and ordinates resistance, we have two curves representing respectively these two kinds of resistance, following the V^2 and the inverse V^2 laws, and we have a third curve velocity, that is, to the product of the abscissæ and ordinates of the curve (Fig. 1). This is of minimum value where the aerodynamic resistance is equal to three times the direct resistance.†

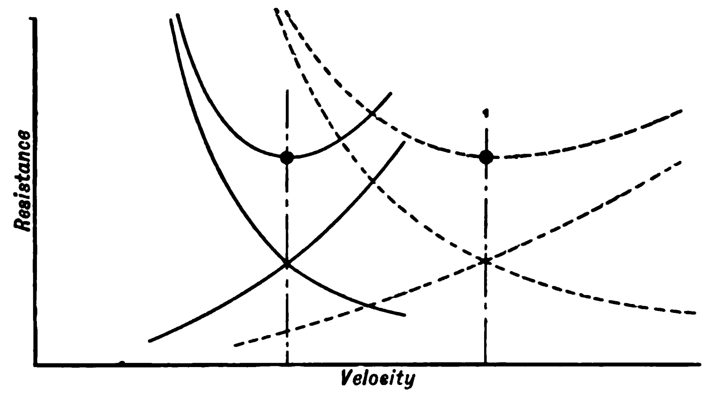
We have hitherto supposed that the bird or aeronaut can alter the angle of his supporting members, but we have not supposed him able to alter the area. If, as is the case with many birds to some degree, we suppose changes of area possible, the conditions become more complicated and we are faced with new and different laws.

For each change of area we have a new pair of curves of aerodynamic and direct resistance, and a new total curve (Fig. 2), and thus we can no longer represent all the possible changes on a two dimensional or plane diagram. But now the object we have in view may be taken into account as a factor limiting the

* "Aerial Flight," Vol. I, Aerodynamics, §§ 164, 176.

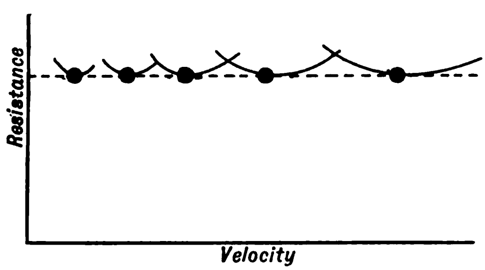
† "Aerial Flight," Vol. I., Aerodynamics, § 164.

FIG. 2.



conditions. Since the practical problem is to get from one point to another with the least possible expenditure of energy, we need only consider the portions of the different curves at and around their points of minimum value. Thus in Fig. 3, if we draw a number of these total

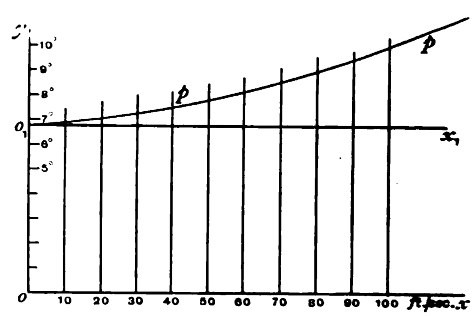
FIG. 3.



curves and draw a curve passing through the minimum point of each, we shall have a curve giving the resistance for variations of velocity on the assumption that the area and angle have been adjusted in every case for minimum value. It is one of the results obtained by the author, that for a given weight sustained this minimum value is constant.* This throws considerable light on the constancy of resistance coefficient for various models and machines at different velocities given as a matter of experience in Table II. In addition to the resistances considered as forming the total in the investigation by which the above result is given, there is a cause of resistance that is best considered apart from the flight resistance proper—that is, the resistance due to the invariable parts of the bird or machine, or body resistance. This body resistance increases (in accordance with the V^2 law) directly as the square of the velocity, and is substantially unaffected by the alterations of area and angle contemplated in the preceding investigation.

To summarise the position, we may (assuming the condition of least resistance to be complied with) suppose the resistance to flight to consist of two parts, one of which is

FIG. 4.



constant and comprises the resistance due to the flight organs, and the other of which, due to the body, varies directly as the square of the velocity. These two kinds of resistance are represented in Fig. 4, in which the constant resistance is given by the horizontal line O x, and the added or body resistance by the line p p.

In Fig. 4 the ordinates give the coefficient of resistance as an angle—the *gliding angle* of free descent.

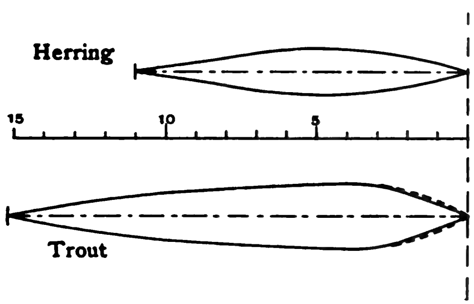
---

* Comp. "Aerial Flight," Vol. I., Aerodynamics, § 166.

It is at the present juncture worthy of note that there is thus a close analogy between the flying machine and an ordinary motor car climbing a steady gradient. The flight resistance corresponds to the gradient resistance, which does not vary with changes of velocity, and the body resistance of the flying machine is strictly analogous to the "wind resistance" of the motor car; it arises from the same identical cause, and varies according to the same law.

In order to diminish as far as possible the body resistance, the body or mechanism should be enclosed by a stream-line or ichthyoid form. It is not known with precision what the correct form of least resistance may be, for no theory is known by which the best form, in the case of a real fluid can be deduced. It is generally understood that forms of smooth

FIG. 5.



contour and fined off stem and stern do not give rise to motion of the discontinuous type,* and this (*i.e.* the absence of discontinuity) is the essential feature of stream-line motion. The author has measured certain fish forms which, reduced to solids of revolution, are given in Fig. 5; these seem rough approximations to paraboloids (in which the axis of revolution is parallel to the *latus rectum*), but in which the maximum section is about 7-16ths from the nose.

The resistance of forms such as those illustrated is not very accurately known. Various observers give it in the case of the ·15 form, that is, about 6 : 1 ratio, as from 1-8th to 1-30th of the resistance of a normal plane of the same "projected area." It is probable that the coefficient of resistance thus defined for a well-designed fish form of 1 : 6 ratio varies as a function of the size and velocity; for small forms at low velocities it may be as high as, or even higher than, ·125, whereas for large bodies it is probable that as low a coefficient as ·06 may be obtained. The author believes that for well formed bodies it is usually between these limits. The present case is merely an example of the want of agreement commonly met with in experimental aerodynamics.

It is evident, referring again to Fig. 4, that for low flight velocities the body resistance becomes relatively unimportant, and the loss of power due to a badly formed stream-line body may be inconsiderable. For high velocities on the contrary, the body resistance, even with the most carefully designed form, may constitute a large part of the total resistance, and the greatest care becomes necessary to prevent the expenditure of power from this cause from becoming excessive.

Having discussed the means by which the body resistance may be minimised, we will now revert to the question of the conditions governing the flight resistance proper, the constant component of Fig. 4.

The influence of variation in the coefficient of skin friction is rendered evident by the curves shown in Fig. 6, in which the line represents the curve of total resistance that results from a reduction in the skin friction corresponding to the difference between the lines 1 and 2; it is evident that the minimum resistance value given by this curve is less than previously.

Several writers—notably Wenham, Langley, Dines, and Maxim—have stated that the influence of skin friction is negligible, and Langley gives the value or the coefficient as approximately ·00015, as against the author's result about fifty times as great. If the value were actually as stated by Langley, skin friction, under the conditions of flight as at present known to us, would in effect be negligible; but there is no doubt that Langley's statement is in error.

If it were possible, the correct way to measure skin friction would be to measure directly the tangential drag experienced by a plane in edgewise motion. In practice the experiments have to be made on a plate of some material possessing thickness, which, strictly speaking, is a departure from the conditions; the author has made determinations in this way by means of an instrument termed an aerodynamic balance,* the plate being made of stream-line section. It is useless to experiment with planes with square cut edges owing to the fact that the air set in motion by the lead-

* See Appendix.

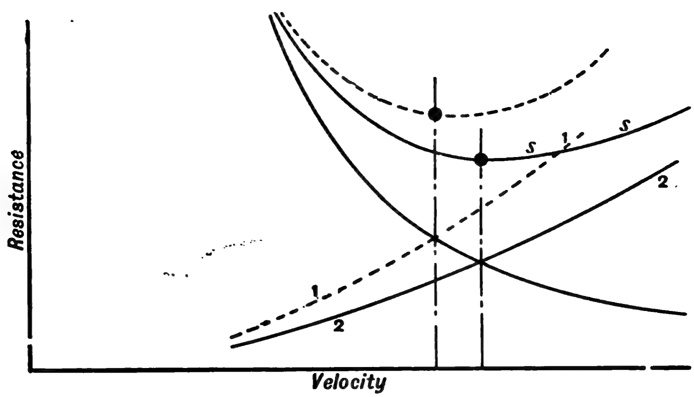
* "Aerial Flight," Vol. I., § 246.

ing edge of the plane relieves the skin-friction on the surfaces along which it passes to a very great extent, and so if a deduction for the edge area be made the calculated coefficient will be far below its true value.

this way. Beyond this the coefficient undoubtedly is less for high velocities and large surfaces, than when the area is small and the velocity low.

The other important factor by which the

FIG. 6.



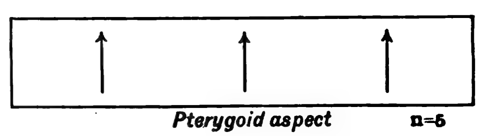
It is not easy by means of apparatus of a portable kind to demonstrate even the existence of skin-friction to an audience, but the following method has been used by the author. If a sphere whose centre of gravity and centre of pressure coincide, be surrounded and supported by fluid in which skin-friction is absent, it will be manifestly impossible for the sphere to acquire rotation or to lose any rotation initially imparted to it, for forces acting between the surface of the sphere and the fluid will have no tangential component, and hence will all pass through the centre; but the force of gravity also passes through the centre; hence all forces acting on the sphere pass through its centre, and they cannot give rise to a couple.*

It is evident that the only direction in which a direct effort can be made to reduce the coefficient of skin-friction is by employing materials as smooth as possible, if not actually going to the length of varnishing or polishing the surfaces. It is known that some small

reduction in the coefficient may be effected in constant flight resistance is influenced is aspect ratio.*

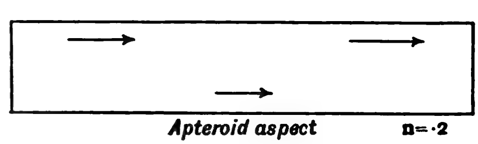
If a given weight is sustained by a plane at a stated angle the area required is less for planes in pterygoid aspect, Fig. 7, than in

FIG. 7.



apteroid aspect, Fig. 8, and as a general proposition the area required is less the greater the aspect ratio. It is a consequence of this

FIG. 8.



* A demonstration by this method was given by the author at a Lecture to the Liverpool Engineering Society, Feb. 9th, 1909. In the experiment, as tried, a small celluloid ball was supported on a jet whose nozzle velocity was probably about 150 feet per second, and the speed and direction of rotation are found to undergo continual change, proving conclusively that skin-friction exists. A rough computation made from the rate of change of rotation and the velocity of the air jet gives a value of the coefficient of the right order of magnitude, as determined by other modes of experiment.

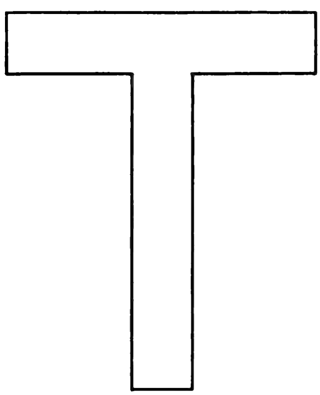
* The term "aspect" in its present usage was first employed by Langley to denote the attitude of a plane in azimuth in relation to its direction of flight. The term "aspect ratio" has been introduced by the author to denote the proportions of the plane or wing surface, *i.e.*, "aspect ratio" is span in terms of fore and aft dimension ("Aerial Flight," Vol. I., Aerodynamics, § 150).

that the use of planes of great aspect ratio results in economy, for the necessarily exposed surface is less, and thus the skin friction is diminished.

The same facts apply equally to supporting members of other than plane forms, and hence a considerable aspect ratio is a *sine qua non* if economy is desired. The aspect ratio employed by nature varies considerably, but amongst birds it is found as low as 4 in the case of the lark and scops owl, and may be as high as 13 in the wandering albatross.

An experiment of a very simple kind, originated by the author some years ago, may be easily made to demonstrate the importance of "aspect ratio." A piece of stout paper cut to the shape of the letter T (Fig. 9) is allowed

FIG. 9.



to fall head first, when it is found to be unstable and will turn over. If, on the other hand, it be let fall stem first, it will be seen to drop vertically like a stone.

When the T assumes accidentally a very slight inclination to its direction of motion the pressure reaction on the head which is in pterygoid (winglike) aspect is greater than that on the tail which is in apteroid aspect. Hence for small angles the centre of pressure is always nearer the head than the centre of gravity and the stem of the T may be regarded as acting as ballast. If the pressure reaction were the same in pterygoid as in apteroid aspect the T would fall equally well (or badly) whether suspended from its head or stem.

A feature commonly found associated with the development of aspect ratio in nature and conducive to the economical sustentation of the load is the arched section, the advantages of which (in connection with mechanical flight) were first clearly established by Horatio Phillips in this country and by Lilienthal in Germany. This feature is illustrated in Fig. 10, which represents the section of the wing

FIG. 10.

(Herring Gull)

of a herring gull; a most remarkable feature associated with the arched section is the dipping front edge which may be observed whenever birds in gliding or soaring flight are seen under sufficiently favourable conditions.

The advantages derived from great aspect ratio and from the dipping front edge are due to the form of motion—the fluid dynamic system—by which the supporting member or aerofoil is surrounded. The author has shown that this system comprises what is termed in hydrodynamic theory a cyclic component, a type of motion with which we are most familiar in the particular case of the vortex ring, and which is sometimes in consequence known as vortex motion.

In an inviscid fluid—the ideal fluid of mathematical theory—cyclic motion can only take place in what is termed a doubly or multiply connected region, that is, a region that is looped by an obstacle; for example, the spaces either surrounding or internal to the surface of an anchor ring are said to be doubly connected. Now, in the case of the wings of a bird or the aerofoil of a flying machine the cyclic motion takes place in the vertical plane of flight, and the greater the aspect ratio the better it lends itself to the type of motion in question; nevertheless, whatever the span of the aerofoil may be, unless we consider it as infinite, the surrounding space remains a simply connected region, and cyclic motion only becomes possible by reason of the viscosity of the fluid.

The manner in which viscosity, however small, gives rise to so fundamental a difference in the behaviour of a fluid is one of the problems at present in progress of solution; it appears to initiate something in the nature of instability in the systems of flow established by theory for the perfect fluid, and so the resulting changes are out of all proportion to

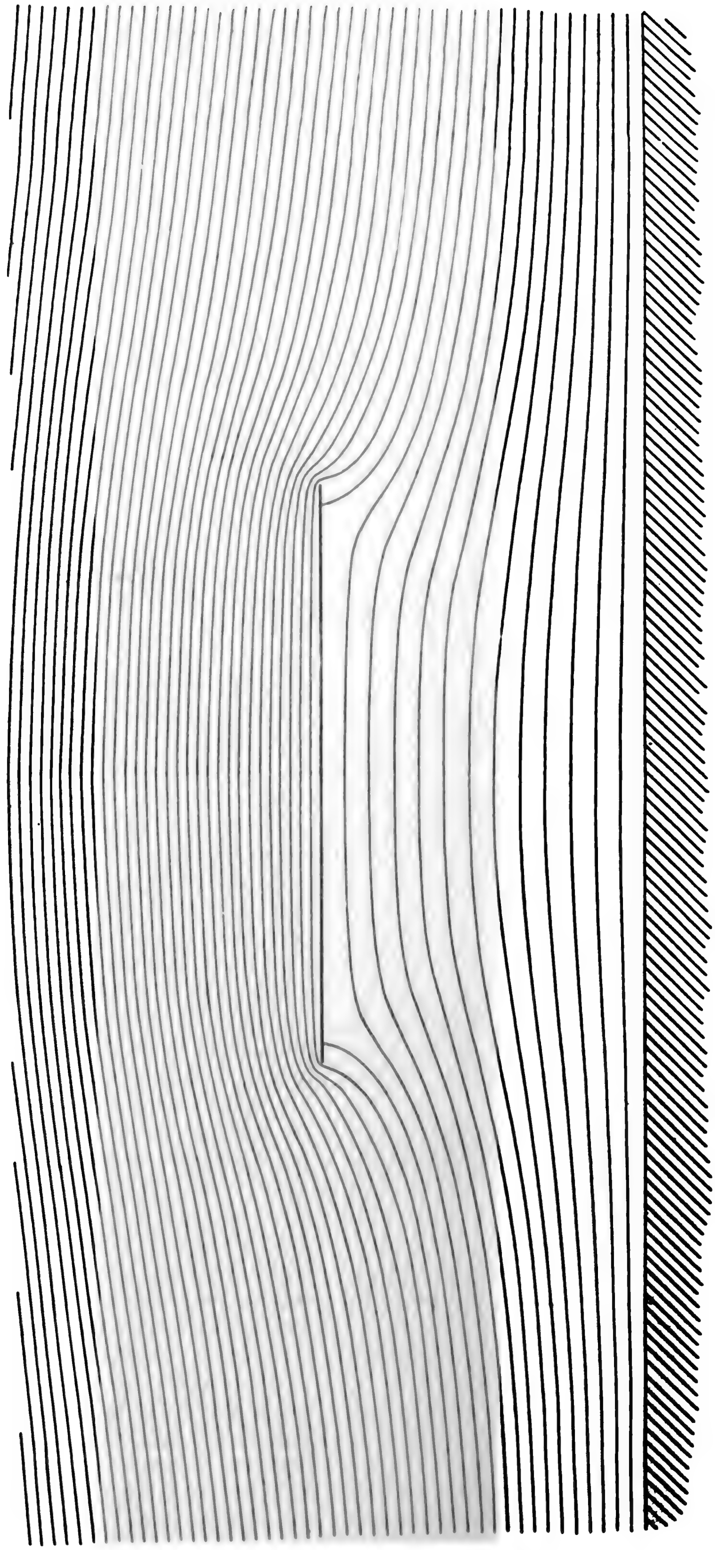


FIG. 11.

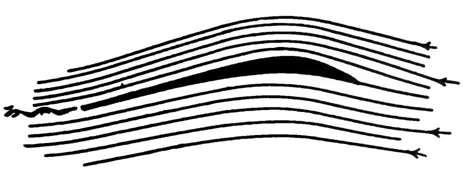
the effect that produces them. In any case the possibility of a cyclic system in a simply connected region in a real fluid must to-day be accepted as established, and for the present purpose it is sufficient to draw attention to the bearing of this fact on the branch of the subject under discussion.*

Fig. 11 represents the ideal case of a cyclic motion about an infinite plane lamina in motion in an inviscid fluid. Here a load will be sustained indefinitely by the aeroplane without any expenditure of energy, the cyclic system superposed on the motion of translation gives rise to the stream-line system depicted which is a conservative system of the general character of a wave on the crest of which the aeroplane is sustained. The system is symmetrical in this case and therefore the diagram may be read in either direction; it will be seen that the fluid rises to meet the plane during its approach, gives up its upward momentum to the plane and receives downward momentum, this exchange of momentum giving rise to the supporting reaction.

FIG. 12.



In a real fluid a plane such as depicted would give rise to a discontinuous system of flow and to take full advantage of the cyclic system the leading edge must dip to meet the upcurrent and the trailing edge must also dip to conform to the direction of the stream-lines. Thus a suitable section is given in Fig. 12. Under actual conditions also the lateral dimension or "span" is not infinite and this results in a continual lateral dissipation of the supporting system which has to be made good by work done by the aerofoil; it is, therefore, necessary to impart a greater downward velocity to the air than that of the upcurrent received.

Thus the cyclic theory of the periptery supplies the key to the solution of the problem of aerofoil design; if the use of that key is not yet fully mastered it is due to the newness of the subject rather than to its intrinsic difficulty.

Basing his investigation on the foregoing theory the author has established certain important relations connecting the form of suction of the aerofoil, the pressure per square foot, and the velocity of flight, proper to least resistance. Thus there is a definite relation between the weight sustained per unit surface and the square of the velocity of flight* that results in the least resistance to flight, and this relation may be calculated with a fair degree of accuracy if the value of the aspect ratio and the coefficient of skin friction are given. The appropriate values (taken from Table IX. from the author's "Aerial Flight") are given in Table III. for different values of aspect ratio from 3 to 8 for values of the coefficient ξ = ·02 and ·01, the aerofoil being taken as of the arched section (or pterygoid form) discussed in the author's work. The value of the constant in the case of a true (or plane) aeroplane is considerably lower.

An interesting point arises in connection with the value of the coefficient ξ. It is known that, other things being equal, ξ diminishes according to some unknown law as the size of a plane is increased. There is also experimental evidence to show that it also becomes less for high velocities. Beyond this, there are theoretical grounds for supposing that the change in respect of velocity is of identical form with the change in respect of size, and that so long as the product of linear size and velocity (L V) is constant, the value of ξ is constant. Now if we design a number of aerofoils of the same aspect ratio to comply with the condition of minimum resistance to support a given weight, W, at different velocities of flight, we know as in Table III., the area multiplied by V^2 is constant, and the area is proportional to the square of the linear dimension: hence L^2 V^2 is constant, or L V is constant. Consequently we have the rather unexpected result that the coefficient of skin friction (assuming the conditions as those of least resistance), is independent of the size or the velocity of the machine. In other words, as soon as we have settled the weight of the machine, and the aspect ratio it is proposed to employ, the value of the appropriate coefficient is determined.

In practice, the extent to which the theore-

* In his "Aerial Flight," Vol. I., the author has discussed the whole question very fully (cc. iii. and iv.). It is there shown that the conditions of double connectivity are simulated by vortex filaments being continuously generated at the right and left hand extremities of the aerofoil which trail behind in the fluid, their contained rotation becoming distributed and their energy dissipated.

* This must not be mistaken for a mere re-statement of the V^2 law; it rests definitely on the proof given in the author's work. That the law of best pressure value corresponds to the V^2 law is counterpart to the fact that the best angles of dip and trail are constant in respect of velocity variations.

tical requirements can be fulfilled, has certain limitations. Constructional considerations prescribe a limit to the aspect ratio that can be employed; secondly, the question of the weight of the aerofoil makes it undesirable to utilise as much surface as the simple theory would indicate; this point is investigated more fully in the author's work, and a general solution is given. Thirdly, the struts, guy wires, &c., used perforce in the aerofoil of a full scale machine offer considerable resistance of a kind that varies roughly as the area employed and the square of the velocity; this resistance has to be considered as part of the direct resistance of Fig 1, and may be dealt with by a special coefficient computed from a trial design, and added to the coefficient of skin-friction; in fact, these resistances in effect augment the skin-friction coefficient. Struts, guys, &c., forming part of the frame of the chassis of the machine, on the other hand, undergo no changes with change of area, and therefore form part of the body resistance.

From computations that the author has made, it would appear probable that the total resistance of the flight organs—the constant resistance of Fig. 4—is in the case of many of the present successful flying machines about 10·1 of the weight, and the difference between this and the co-efficient of traction, given in Table I., is that properly classed as body resistance; however, the machines vary considerably amongst themselves, and computations made on data at present ascertainable cannot be implicitly relied upon; an error of 10 per cent. might easily exist.

In the case of birds it is probable that the coefficient of traction is commonly from 12 per cent. to 20 per cent., about one-sixth of which is body resistance.

It is worthy of remark that the velocity of flight of the various present-day machines is not widely different. This is due, on the one hand, to the fact that at speeds below 30-35 miles per hour through the air the maintenance of equilibrium becomes a grave difficulty, so much so as to render flight dangerous except in the calmest weather, and on the other hand to the fact that the maximum possible velocity of flight is proportional to the power carried, and as yet the petrol motor has not been sufficiently reduced in weight to leave a great margin of horse-power. It is natural that working under the restriction as to horse-power the earliest successful attempts at flight should be made at speeds very little in excess of the minimum safe limit!

HOME INDUSTRIES.

Electric Driving.—It is a little surprising that electrical driving has not, as yet, made much headway in the cotton and woollen industries. There are more than 53,000,000 spindles dealing with the raw material of cotton, or, including spindles producing waste yarns, over 57,000,000, and the number of looms exceeds 739,000. But very few of these spindles and looms are electrically driven. Nor is it

likely that whilst the present depression in the cotton trade lasts, many spinners and manufacturers will be prepared to reorganise their power plant, and instal electricity as a motive power. It may be expected, however, that when the next cycle of prosperity comes, there will be considerable resort to electricity. Its advantages, as they apply to cotton machinery, are many. It saves friction. Even with the highly-perfected steam drive there is considerable loss in power throughout the mill, due to friction in the engine, the rope race, the shafting, and the belting. A correspondent of *The Times* (October 20th) gives a recent case of a mill tested, when it was found that the engine had to develop 1,252·20 horse-power, in order to drive the mill satisfactorily, although the machines only needed 895·96 horse-power as a *maximum*. Taking a percentage on the power required for useful work, 39·76 per cent. extra power was needed beyond that for working the machines themselves. If the mill had been electrically driven, and the current had been bought from a supply corporation, the consumer would have had to pay for only 861·41 horse-power, of which 783·98 horse-power would be utilised in useful work. The difference between the latter figure, and the 895·96 horse-power which would be absorbed if all the machinery were running, is accounted for by the fact that, during part of the time, doffing, grinding, stripping and similar operations have the effect of keeping certain machines standing. Other advantages of electrical driving, as compared with steam, are—(1) that the prime mover and the machinery can be placed in any relative position, and that each machine can be driven independently without reference to the others; (2) the steadiness of the drive is increased; (3) a more regular and therefore better selling yarn is produced; (4) there is a greater immunity from general breakdown; (5) in the erection of new mills much lighter structures can be designed, and utilised by dispensing with shafting, pulleys, and belting, and so saving much weight, while in combination with buildings of reinforced concrete, electrically driven mills can be constructed at smaller cost than the mill buildings now used. The mills already electrified are examples of what can be done, but each mill must be individually considered, and treated on its own merits.

Canals and Waterways.—Volume VI. of the Report of the Royal Commission on Canals and Waterways has just been issued. It contains the reports on the waterways of France and Belgium, Germany and Holland, drawn up by Mr. W. H. Lindley, who was appointed an Assistant Commissioner for this purpose. The report contains a mass of information upon foreign waterways, and shows in great detail how much these several States have done to preserve and extend their inland waterways. A different policy has been followed in this country. So long ago as 1121 Henry I. deepened and rendered "partially navigable" the old Roman Fosse Dyke, which, in a sense, may be called the first British canal, and in 1563 a pound lock canal was constructed from Topsham to Exeter, similar in all essential points to one of the present day, but it was not until 1760 that a navigable canal of considerable length—from the Mersey to St. Helens—was completed, and a century later the great railway companies obtained the control of our inland navigation system which has brought it to its present lamentable condition. The demonstration of the evils resulting from this policy by various Departmental Committees and Royal Commissions has produced some remedial legislation on the subject, but it has hitherto yielded little or no result.

The Working of the Patents Act.—It is made plain by the reports of various Continental manufacturers' organisations that they regard the new Patents Act in this country as putting two serious obstacles in their way. The question of international patent law was one of the subjects discussed at the annual meeting of the International Society for Industrial Legal Rights, held at Nancy, and the following resolution was passed:—"The Congress is of opinion that no country should compulsorily enforce the working of patents, and it is in the highest degree desirable that the law on the subject should at least be uniform in all countries." It is suggested that the working of a patent in any one country should be considered sufficient, and in case of its not being worked at all the penalty should not be the withdrawal of the patent rights, but the legal right for a license on the part of anyone desirous of working the patent. The congress is further of opinion that in any case the patent should not be annulled if the patentee can show that he has offered to grant licenses on fair terms to interested parties and these have refused to take them up. Finally, the patent rights should not be withdrawn if it can be shown that the industry in the country itself is equal to that represented by the quantity of the patented articles in question actually imported.

The Census of Production (1907).—The Census of Production discloses some striking facts with regard to the relative magnitudes and values of the home and export trades in the various goods. It will surprise many to find that the export of broad woollens is of an average quality higher than such as are retained for home use, yet it appears that the average value of those produced is 2s. 1¾d., and the average of exports 2s. 8½d. The export of these is 50·4 per cent. of the production in quantity, but 64·3 per cent. in value. So in narrow woollens, a class including low dress Melton and similar goods, as well as woollen trouserings, exported goods are on the whole of a superior kind to those made for the home trade. In broad worsted coatings, 44 per cent. of which are exported, the export and the general price are almost equal. Carpets, 36 per cent. of which are exported, have the same average price of 2s. 7d. alike in export and production. The blanket trade is three parts home trade and the blankets exported are valued lower by 7½d. a pair than the

9s. 5d., which is the 1907 value of all that were manufactured. Flannels and delaines are still more of a home trade than blankets, the exported proportion being less than 20 per cent. Of plush only 8.7 per cent. of the yardage goes abroad, and of damasks, tapestry, and furniture stuffs, only 6 per cent. Damask weaving is a dwindling trade and there is not much business done at home in tapestry looms. Roughly the home and shipping branches of the woollen and worsted cloth industries are about equal in importance. Of coal, 265,134,000 tons were raised in 1907, and of this quantity only 182,914,000 remained in the United Kingdom.

The Cotton Position.—There is no longer any doubt that the American cotton crop will be a short one. The damage inflicted to the crops of Louisiana and Missisippi by the hurricane of September 20th, was exaggerated, but the loss sustained in both yield and condition of the staple is nevertheless considerable. In many sections, some of the cotton carried to the ground by the violent winds has been saved, but the quality and grade are found to be affected. At present cotton is plentiful owing to the rush to market, but values have reached such a level that cotton mills cannot produce finished goods, and sell them at a remunerative price. In consequence, there is a movement on foot on the part of manufacturers to curtail production, and according to the *New York Journal of Commerce*, "if the present plans of manufacturers mature, the reduction in the consumption will amount to one million bales in the United States alone. The proposal is for a short time to the extent of 224 hours, during the present cotton season, the agreements to become effective if not less than seven million spindles shall have been signed up. To save one million bales, roughly, the equivalent of a stoppage of 6 per cent. of all the spindles in the States for a year is necessary. The *Journal of Commerce* says that even the curtailment of a part of the seven million spindles is not likely to become effective in the immediate future, "as many of the mills that will sign an agreement will be unable to fill present orders without steady running well into January." It is difficult to get at the truth from contradictory statements of this kind. If a mill has orders that will keep it working until January, it is not probable that it will bind itself to shut up for 224 hours after that time. If the present high prices continue, it is pretty certain that there will be a considerable decrease in the use of cotton in the United States, but a reduction in the consumption of one million bales is quite another matter.

MEETINGS FOR THE ENSUING WEEK

MONDAY, Nov. 1...Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Major P. G. Craigie, "Farm Labour and the Cost of Production."

Royal Institution, Albemarle-street, W., 3 p.m. General Monthly Meeting.

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. J. H. Coste, "Technical Gas Calorimetry." 2. Messrs. W. P. Jorissen and J. Rutten, "Naphthalene Picrate and the Quantitative Determination of Naphthalene." 3. Mr. J. C. Stead, "Some Notes upon the Manufacture of Large Blocks of Artificial Stone from Sand and Lime."

British Architects, 9, Conduit-street, W., 8 p.m. 1. President's Address. 2. Presentation of Royal Gold Medal to Dr. Arthur J. Evans, and Address by Dr. Evans on "Recent Discoveries in Crete."

London Institution, Finsbury-circus, E.C., 5 p.m. Dr. P. C. Mitchell, "The Feeding of Animals in Captivity."

TUESDAY, Nov. 2...Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Address by the President, Mr. James C. Inglis. 2. Reception in the Library after the Meeting.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Sir John Cockburn, "Signs of Imperial Solidarity."

WEDNESDAY, Nov. 3...Geological, Burlington-house, W., 8 p.m. 1. Mr. S. S. Buckman, *a.* "Certain Jurassic (Lias Oolite) Strata of South Dorset, and their Correlation." *b.* "Certain Jurassic (Inferior Oolite) Species of Ammonites and Brachiopoda." 2. Dr. W. F. Hume, *a.* "The Cretaceous and Eocene Strata of Egypt." *b.* "The Granite Ridges of Kharga Oasis: Intrusive or Tectonic?"

Royal Archæological Institution, 20, Hanover-square, W., 4½ p.m. Mr. R. Garraway Rice, "Portions of Sussex Churches which can be dated from Bequests in Early Wills." (Part II.)

THURSDAY, Nov. 4...Linnean, Burlington-house, W., 8 p.m. Prof. H. H. W. Pearson, "Some Account of the Field Botany of Namaqualand, Damaraland, and South Angola."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. H. M. Dawson and Miss H. S. Leslie, "Dynamics of the Reaction between Iodine and Acetone." 2. Mr. J. F. Thorpe, "The Formation and Reactions of Imino Compounds." (Part XI.) "The Formation of 1-imino-2-cyanocylopentane from Adiponitrile."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. F. Martin Duncan, "The Romance of Plant Life."

Civil and Mechanical Engineers, Caxton-hall, Westminster, S.W., 8 p.m. Mr. A. S. E. Ackermann, "Technical Popular Fallacies."

East India Association, Caxton-hall, Westminster, S.W., 4 p.m. Mr. Atul Chandra Chatterjee, "The Need and Methods of Industrial Development in India."

FRIDAY, Nov. 5...African Society, Trocadero Restaurant, Shaftesbury-avenue, W., 8 p.m. Address by Herr Dernburg.

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. W. D. Scott-Moncrieff, "Drainage and Sewage Disposal."

Geologists' Association, University College, W.C., 8 p.m. Conversazione.

Anthropological, 50, Great Russell-street, W.C., 8½ p.m. (Huxley Memorial Lecture.) Prof. Gustaf Retzius, "The North-European Races."

Engineers, Caxton-hall, Westminster, S.W., 7½ p.m. Dr. David Sommerville, "Some Observations on the Chemistry and Bacteriology of Sewage Purification."

SATURDAY, Nov. 6...Educational Handwork Association (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 3 p.m. Dr. T. P. Nunn, "The Educational Value of Handwork Teaching."

Journal of the Royal Society of Arts.

No. 2,972. VOL. LVII.

FRIDAY, NOVEMBER 5, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CANTOR LECTURES ON "AERIAL FLIGHT."

The Secretary very greatly regrets that Mr. F. W. Lanchester having failed to supply the MS. of the second lecture of the course on "Aerial Flight," it is not possible to publish it in this number of the *Journal*. It is hardly necessary to say that every effort has been made to induce Mr. Lanchester to fulfil his contract with the Society, and the Secretary can only express his profound regret at his lack of success.

No information as yet can be given as to the publication of this, or the third Lecture.

CANTOR LECTURES ON "ARTIFICIAL ILLUMINATION."

The Cantor Lectures on "Modern Methods of Artificial Illumination," by Mr. LEON GASTER, Editor of the *Illuminating Engineer*, have been re-printed from the *Journal*, and the pamphlet (price two shillings) can be obtained on application to the Secretary, Royal Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures, which have been published separately and are still on sale, can also be obtained on application.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One-Hundred-and-Fifty-Sixth Session will be held on Wednesday evening, the 17th of November, at 8 p.m., when an address will be delivered by SIR WILLIAM H. WHITE, K.C.B., LL.D., F.R.S., Vice-President and Chairman of the Council. The subject of the address will be "An Imperial Navy."

The following arrangements have been made for meetings previous to Christmas :--

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

NOVEMBER 24.—T. THORNE BAKER, F.R.P.S., "Photo-Telegraphy."

DECEMBER 1.—HON. RICHARD C. PARSONS, M.A., "Resilient Wheels for Vehicles."

DECEMBER 8.—JAMES BUCKLAND, "The Destruction of Plumage Birds."

DECEMBER 15.—H. PEARSON, "The Diamond Fields of Brazil."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock :—

NOVEMBER 30. — SAMUEL SIMPSON, B.Sc., M.R.A.S.E., "Agricultural Development in Nyasaland."

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

DECEMBER 9.—SIR JAMES WILSON, K.C.S.I., "The Punjab."

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

CHARLES CYRIL TURNER, "Aeronautics." Four Lectures.

LECTURE I.—NOV. 29—Aerostats and aeronefs—Ballooning and its future—Possible lines of development—Kites—Birds—Is flapping wing flight imitable? —Soaring flight—Gliding flight—Action of the air on plane and curved surfaces—The leading or "entering" edge—Aspect ratio—The inclined plane—The curved plane — The concavo-convex plane — The gliding angle—Air resistance—Stream-line form—The atmosphere — Different qualities of air—Air propellers.

LECTURE II.—DEC. 6.—Dirigible balloons—Comparative efficiency of different types—The elevator—The ballonnet—The compartment system—Methods of suspension—Stability—Motors and propellers—The ascent and the landing—Harbours—Capacity and utility of dirigible balloons.

LECTURE III. — DEC. 13. — Aeroplanes, helicopters, and ornithopters — Present failure of the two latter—The simple glider—Principles of stability. —The question of automatic stability—The relation of

speed to stability—Various methods of obtaining stability — The compartment system — Adjustable planes—Flexible planes—Some suggestions—Starting and alighting—Position of the pilot.

LECTURE IV.—DEC. 20.—Flying-machine motors and propellers—Specialised flying-machines—Differentiation of type—Limitations—Practical results—Uses of the flying-machine—Navigation of the air—Flying by night—Special maps and landmarks—Possibilities in war.

Papers to be read after Christmas :—

H. S. SMITH, "Oxy-Acetylene Welding."

E. COOKE, "The Teaching of Design."

CHARLES JOHN STEWART (Public Trustee), "The Public Trustee and his Work."

CYRIL DAVENPORT, "Miniatures."

KENNETH GRAY, "Heating and Ventilation."

E. B. HAVELL, late Superintendent Calcutta School of Art and Art Gallery, "Art Administration in India."

GEORGE OWEN DUNN, M.Inst.C.E., Chairman, Bombay City Improvement Trust, 1904-1909, "The Bombay Housing Question."

SIR RICHARD CARNAC TEMPLE, Bart., C.I.E., "The People of Burma."

DR. JOHN MCCALL, Agent-General for Tasmania, "Fruit Production in the British Empire."

C. G. ZANDER, "Printing Inks."

SYDNEY PERKS, F.R.I.B.A., F.S.A., "The Guildhall: the recent discoveries and restoration."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

January 13, February 17, March 10, April 21 May 26.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

February 1, March 1, May 3.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

ALAN S. COLE, C.B., "Textile Ornamentation." Three Lectures.

January 17, 24, 31.

PROFESSOR W. WATSON, D.Sc., F.R.S., "The Petrol Motor." Four Lectures.

February 7, 14, 21, 28.

LAWRENCE WEAVER, F.S.A., "Lead Work." Two Lectures.

March 7, 14.

ALFRED B. SEARLE, M.S.C.I., "Modern Methods of Brick-making." Four Lectures.

April 11, 18, 25, May 2.

JUVENILE LECTURES.

Wednesday evenings, January 5 and 12, 1910, at 5 o'clock :—

PROFESSOR HAROLD B. DIXON, M.A., F.R.S., "The Chemistry of Flame." Two Lectures.

THE PLACE OF RESEARCH IN EDUCATION.*

By HENRY A. MIERS, D.Sc., M.A., F.R.S.,
Principal of the University of London.

The word research has played a very important part in most educational writings during recent years. There was a time when research was supposed to be the province of dry-as-dust university professors, and was not regarded as having many points of contact with ordinary life, or with ordinary education; the man who pursued research might be a teacher with zeal and some leisure for investigation, but was more often a man of means to whom it was a pleasure. He was also regarded as different in kind from the inventor, whose main object was to make a fortune. In Sir James Murray's New English Dictionary the earliest use of the word "researcher" in its modern sense is in a letter from *The Times* of 1883; and there it is actually employed in contrast to teacher.

Faraday is, perhaps, the most splendid example in the annals of British, or, indeed, of European, science of the born investigator—the man imbued with the spirit of scientific research. He was also a heaven-born teacher, and no better lectures than his have ever been delivered to a popular audience; he made the Royal Institution fashionable for London society. But in those days the audience expected to learn from lectures and not by practising the methods of the lecturer; he as a researcher was living on a different plane, and only descended to their level when he came before them as a teacher.

This gulf between teaching and research has been to a large extent obliterated by the universities.

With the rapid growth of the industrial applications of scientific discoveries, which succeeded one another with bewildering rapidity, it has been realised that the training of investigators is one of the most important functions of the universities, and, accompanying the cry for technical education, came the demand for the endowment of research. The University Commission in 1877 recommended the institution of research fellowships. Ever since the days when the Royal Society was founded by a few investigators at Oxford, the universities had from time to time produced small groups of men who were inspired by a zeal for scientific inquiry. Universities were henceforth to be expected to produce a regular succession of researchers.

So remarkable have been the results upon German industry of the scientific labours of highly trained investigators, so fruitful has been been the expenditure of public money upon their training, such astonishing developments have followed the employment of skilled experimentalists in industry and commerce, that the benefits of research are universally recognised. They are even recognised by politicians, and are frequently reckoned in terms of exports. Such achievements as the manufacture of aniline dyes and artificial indigo are familiar examples of the beneficial

* Reprinted from the *Standard* of Nov. 1, 1909.

results of scientific investigation, and it is realised that if a country falls behind in the training of discoverers, the national loss is to be reckoned in millions.

Institutions devoted to special research, such as our National Physical Laboratory and Lister Institute, are now being founded in most countries, manned by staffs of earnest workers trained in the universities and engaged upon systematic inquiries. It is even beginning to be recognised that this work need not necessarily be accompanied by immediate financial and industrial success. The discoveries which have no immediate application sometimes prove to be the most important of all, for they may lead to the establishment of the most fundamental principles. The extraordinarily rapid development of the applications of electricity was in no small measure due to the fact that the mathematical principles on which these applications were based had been already worked out by the mathematical physicists. We may be sure that there will be no lack of research into rubber substitutes, light motors, flying machines, and the other discoveries that lead to fame or fortune; neither is it likely that the investigations of bacteriology, or the search for the causes and the remedies of the mysterious diseases that terrify the pnblic mind, will be allowed to flag; but it is recognised now that from private endowments and the public purse funds should be forthcoming not only for these objects, but also for advanced scientific researches of all sorts; and that it is the duty of the universities to train the brightest intellects for their study.

But, though the industrial applications gave a new stimulus to research as a recognised part of University education, and although in the minds of the public the word may be connected mainly with work which leads to such results, the introduction of research has really effected a far more profound revolution in education. It has meant the introduction of the research spirit. Without this the thing itself may from the educational point of view become a mere shadow.

The teacher who sets his pupil to make observations or to collect details for the investigation which he is himself pursuing, may be doing good service to the cause of science or of learning, and to his own reputation, but unless he also inspires his pupil with an interest in the object to which the work is directed, and a passion for discovery, he may not be doing better service towards the education of the student than by any other exercise.

For, after all, the educational value of research, apart from the actual value of the discoveries made and the materials amassed for further advance, depends entirely upon the inspiration of the teacher and the response of the student. As flint strikes fire from steel, so, when teacher and pupil meet in the clash of original thought do their minds glow with the ardour of discovery; but without that mutual enthusiasm the process of research may be as uninspiring as it was when the professor confined his original work to his private room or laboratory. Here, as elsewhere, all depends upon the individual; and it is quite possible for a student to prosecute what is called research under an unsympathetic teacher without ever understanding the true spirit of it.

In all the best and most successful developments of higher education a great deal more than this has been done; not only has the success of the applied sciences introduced a new method into their teaching, and made investigation a necessary part of the student's work, but the scientific method has also been communicated like a fever to all branches of learning, and has set them aglow with new activity. It has been discovered that the taste and power for investigation may be acquired by students, and the inspiration of a teacher, who is immersed in research, may communicate a zeal for it to his pupils, that they may become his most valuable assistants, that in them he may build up a school to bring fame to himself and his university, and that his pupils may go out into the world to hand on the lamp of investigation in turn to their followers. When degrees were given for research, and the university seal was set upon investigation as an integral part of a university course, a new chapter was opened in the book of education; and with this advance is bound up the whole system of seminars and advanced courses, which are designed to bring the students into contact with recent discovery and with the original thought of contemporary investigators.

Most British universities now grant certain degrees for research, and it has become the practice to insist upon some evidence of original work or of the power to perform it on the part of the teacher before he is appointed. It is recognised that this will inspire him in the work of instruction. In history, philosophy, science, economics, language, and literature, in almost all the field of educational work, research is demanded; the success of a school is gauged by its output of such work; and the reputation of the teacher is in no small degree measured by the productive activity of his pupils.

So potent is this new force, the spirit of research, in higher education that without it no university teaching is likely to be able to hold its own; the classrooms and the laboratory must be permeated by it if they are to be the scene of successful training. If investigation is not carried on by students, their teachers, at any rate, should be investigators. Let the classics be taught by men who have themselves studied the original manuscripts in foreign libraries, or pursued philological researches; let the professor of history have a first-hand acquaintance, as a worker, with the records that he expounds and the evidence that he describes; let the science professor be one whose name is conspicuous in the journals of the learned societies. The university teaching of ancient history must take account of Minoan civilisation and all the other recent discoveries of the archæologist; the teaching of languages must not disregard the labours of the students of phonetics;

the professor of theology must be familiar with patristic investigation or the modern Higher Criticism; the philosopher, the mathematician, the economist should be themselves active workers who are contributing to the progress of their sciences. Only thus will advanced teaching be conducted in the spirit of living study. There is, or ought to be, no place for the university professor who is not moving with the restless tide of advancing knowledge; who is not himself one of the forces that direct it. To be successful, teaching and research must go on side by side, each drawing vitality from the other. The mere knowledge that the professor or the reader is himself pursuing investigations is enough to stimulate the imagination of the student if he is allowed to see the fruit of those investigations in the work of the lecture or the classroom; how much more stimulating is it if he is himself allowed to take part in his teacher's researches, and if they are made part of his university course!

On the other hand, so exacting are the requirements of modern examinations, and so crowded is the modern curriculum, that there is not always time for this even when the desire is present. For this reason the endowments most required just now are scholarships or fellowships which will enable picked students to remain at their universities two or three years after completing the degree course, and before going out to their work in the world, and to devote those years to research under the direction of their teachers. The universities should be the centres of research in every conceivable subject; nowhere else can the happy union of teaching and investigation be effected. It is not sufficient to endow young men and women, and to leave them free to prosecute their own investigations; in nine instances out of ten they will set to work in the wrong way or on the wrong problem. It is cruel to appoint young teachers fresh from their university examinations, and to expect them to carry on their own researches, and direct the researches of others if they have not themselves had some training therein. But, given teachers who are investigators and students who are endowed and retained for a year or two in order to devote themselves to research under their leadership, the universities will be the oracles from which answers will be sought to the complex riddles of modern life and modern thought; when any new problem arises they will be asked to undertake its investigation.

One more consideration may be urged: it is not only for the properly prepared student that research calls. The inherent interest of original work as compared with routine exercises opens up possibilities in any subject, even for those whose training has been in something quite different. Persons of mature mind whose education has been purely literary, are sometimes able to take up with enthusiasm original research in science under proper guidance without going through the preliminary course; or the scientific student may become, say, an ardent historical investigator. Persons of more than undergraduate age will not desire or be able to go through the complete course of a new subject from its elementary to its final stage, but they can begin at the other end, and enter it by embarking on original work at once under a leader of experience. This view, though it may be highly unorthodox, is based upon my personal experience with advanced pupils, and I know it to be true.

INTERNATIONAL EXHIBITIONS.

A short time ago, Mr. H. Greville Montgomery, M.P., published a pamphlet on "International Exhibitions." Mr. Montgomery's principal object was to discuss the value of such exhibitions to manufacturers, and the consequent desirability of this country taking part in them. Mr. Montgomery criticises the past action of the Government as regards exhibitions, and is strongly in favour of an independent Consultative Committee of Manufacturers, such as has existed for a considerable time in France.

He also remarks that the object of the Government is political, rather than commercial, and that it is consequently hard on individual exhibitors that they should be called upon to represent the country. No doubt there is a certain amount of reason in this argument. But the "political" object of the Government is to advance the industrial and commercial interests of the country, and though it can never be quite certain whether it is to the advantage of an individual manufacturer to exhibit, there can be no question whatever that it is to the general interests of the country that it should be represented at important International Exhibitions. It also appears to be fairly certain that the beneficial results of such exhibitions are not experienced only by the individual who may represent a particular trade, but by the trade in general.

Whether or no individual exhibitors profit by exhibiting is a question difficult, if not impossible, to answer. Men of business are not very keen to give information about their own concerns, and whether an exhibitor has made a profit or not at an exhibition is a matter which he very properly prefers, in most cases, to keep to himself.

Some firms require advertising, others do not. A firm with its hands full of business, which is not anxious to extend that business—supposing such a firm to exist—has no reason for exhibiting any more than it has for advertising. But it is a fair argument that if a firm wishes to advertise it can get as much publicity, at a cheaper rate, by putting up a stall in a good exhibition than it can by advertising in other ways.

Mr. Montgomery objects to the fact that International Exhibitions have now become "pleasure shows and fairs." There is no doubt about this fact. But there is also no doubt that the side-shows alone would not pay without the assistance of the serious

business element. Everyone who knows anything about exhibitions is perfectly well aware that a great majority of the visitors go to the amusements, and for the sake of the amusements. But most of them look at the exhibits as well, and there is also a large proportion of visitors who go solely for the exhibits.

It is probable that the Board of Trade is fairly well conversant with the views of manufacturers, and if they are not, they certainly ought to be. There is no difficulty in ascertaining what those views are without a representative committee being formed. At the same time, it it very probable that such a committee might be useful in this country, as it certainly has been in France.

The question, "does it pay to exhibit?" whether it refers to an individual or to a country, is not easily answered. The committee whose action Mr. Montgomery criticises were inclined to the affirmative answer, and the bulk of the industrial community appears to agree with them.

CHINESE WILD SILK.

M. Francis Marre, writing in *Cosmos*, gives some interesting particulars concerning the wild silk industry of China. A certain quantity of this silk, known under the name "water-eel," is annually imported into France to be worked up in the factories of Lyons and Avignon, but the greater part of it finds its way to America, where it is made into a stuff called "radjab." Of late years, however, a considerable amount has been employed in the manufacture of balloons, a purpose for which it is peculiarly fitted by its strength and toughness.

The silk is obtained from a very common Chinese variety of the oak silkworm (*Antherea Pernyi*). The larva feeds on the leaves of the *Cudrania triloba*, a dwarf oak which grows plentifully on the hills of Ho-Nan, Süchwan and Kweichou. A warm, moist climate prevails almost all the year round in this mountainous district.

The cocoons of the oak silkworm are treated quite differently from those of the domestic silkworm which is fed on mulberry leaves. They are hung in long festoons sheltered from the sun—generally in buffalo-sheds, in order that they may be kept at a constant warm temperature. They remain thus until the Feast of Spring (at the end of January or the beginning of February), when they are removed and hung up in a large room, of which all the doors and windows are carefully stopped. A hole is made in the middle of the roof to allow the escape of the smoke from a stove which is placed in the middle of the room. The stove is kept steadily burning for twenty days; at the end of this period the moths emerge from the cocoons and pairing immediately begins; the males and females are then separated, the latter being placed in palm-leaf baskets, where they lay their eggs. This operation takes about five days. Each female lays on an average some sixty eggs, which are about ten times the size of a mulberry silkworm's egg. After another interval of from fifteen to twenty days, spent in the room which has been closed and heated as before, the worms are hatched and are then taken in the baskets to the places where their food grows. The baskets are set down under the dwarf oaks, the flexible young twigs of which are arranged by the natives so as to make it easy for the worms to climb up to the leaves.

The worm feeds for two months, and then begins to make its cocoon, an operation which takes a week. The cocoons are collected towards the close of May, *i.e.*, from three and a half to four months after the removal from the warm chamber.

The silk is wound and spun in two ways. In the first, which is used to produce a coarse material, the thread is spun from twenty cocoons. Silk of this kind is manufactured almost entirely at Süchwan. In the second the thread is spun from eight cocoons, and silk of this kind, which is made for the most part at Kweichou, is in greater demand for export purposes.

A pound of cocoons produces, as a rule, 240 grammes of fine silk. The average price varies from year to year. In 1907 it was 15 francs the kilogramme; in 1908, 22·6 francs.

THE NORWEGIAN FISHING INDUSTRY.

The Norwegian winter cod fisheries begin, as a general rule, during the first part of January each year, and last until June. These fisheries are conducted along the shores of the central and northern parts of the country, the Lofoten Islands from remote ages having been considered the best grounds. During the season, the fishermen gather at the several fishing stations in these islands from all parts of the north country. With the modern and larger craft now used, many of them provided with motors, the men are enabled to frequent more distant fishing banks, and it has therefore been found more profitable than formerly to fish much further south, where the banks are farther out to sea. The fish are seldom taken more than twenty miles off shore along the Lofoten Islands, and the best catches there are often made only two to three miles from shore. Nets, set lines, and hand lines are used indiscriminately. Some 85,000 men, with 19,000 craft of different kinds and dimensions, are annually engaged in the Norwegian winter cod fisheries. The winter cod is prepared for market by the Norwegians in two different ways, either by what is known to the trade as "stockfish," or else by what is termed "klipfish." The latter, according to the American Consul at Christiania, is known in Latin countries, where both kinds find their best market as "bacalao." In the preparation of stockfish, after the head and entrails have been removed, the fish are strung together in pairs by the tail fins, and hung, unsalted, on horizontal poles resting on beams, placed on uprights, where they are left

until perfectly dried. For klipfish, the head and entrails are removed, the fish split along the belly, and the upper part of the backbone removed. The fish is then salted, and piled in suitable buildings in regular layers, and finally in due course of time, taken out, worked free of surplus salt, and carefully cleaned of black membranes on the belly side, and then cured in places where suitable flat rocks are found convenient for the purpose. Sometimes more than 100,000 fish may be prepared this way in one place, giving employment to a great number of persons—mostly women and children. Klipfish is well known under the general appellation of codfish (salted). Among the by-products of cod are the livers, from which is extracted oil prepared either for medicinal or mechanical purposes, and the roes. The roes are, to some extent, prepared and canned for food, and by far the larger portion is salted in barrels and exported to France and Spain, where they are used at the sardine fisheries. The heads of cod and the backbones of the klipfish are dried and ground for fertilizers. The number of cod and the by-products obtained during the last season were 54,000,000 cod, of which 26,000,000 were prepared as "stockfish," and 24,000,000 as "klipfish," 47,000 barrels of medicinal cod-liver oil, 24,700 barrels of livers for machine oils, and 41,900 barrels of roes. The prices paid to the fishermen vary considerably, according to time and place. The average catch at the Norwegian cod fisheries for a period of forty-two years covered by statistical reports is 50,700,000 codfish per annum, and this figure was reached in 1909 for the first time since the year 1897.

SECOND INTERNATIONAL FOOD CONGRESS.

This year's Congress, just held in Paris, was devoted to the definitions of such operations as might be recognised in the manufacture of alimentary substances.

In passing, it may be said, that when these definitions are complete, they will form a guide of an irreproachable character to all who are concerned in the production or handling of food and alimentary substances. It will not be possible, however, to translate into law the various findings until analytical methods are unified, and a complete system of standardisation has been set up in every country—a task to which next year's Congress will probably be devoted.

The Congress this year was held in the College of Medicine, Paris, which was kindly given up by the Faculty to its deliberations, during the week (October 17th to 24th).

Over 2,000 members subscribed their names, and they hailed from 28 different countries throughout the world. The official opening took place on Monday, the 18th October, and was presided over by M. Ruau, the distinguished Minister of Agriculture of France.

The various food and alimentary substances were grouped together under general headings, which formed the designations of sections, and the order of procedure was as follows:—

Each subject was discussed and a definition arrived at by a vote. This definition, or resolution, was considered to be the finding of the Section, and was thereafter referred to the Hygienic Section, which discussed the matter from the point of view of Health and Hygiene.

The Sections were as follows:—I. Drinks, including wine, liqueurs, cider, beer, syrup, and vinegar. II. Bakery Products, including flour, bread and pastry. III. Confectionery, including sugar, honey, cocoa, and chocolate. IV. Grocery and Spices, including tea, coffee, mustard, and salt. V. Dairy Produce, including milk, cream, condensed milk, butter, cheese, and eggs. VI. Meat Industry, as also oils, edible fats, bacon curing, sausages, preserved fruits, and vegetables. VII. Drugs, essential oils, chemical products, mineral waters, and ice.

In all these sections there were continuous discussions until resolutions were arrived at, and the results will be published in Proceedings ("Compte Rendu") in due course, and this will form a complete book of reference on the sophistications of food, and the limits to which they will be tolerated in all countries.

Some of the findings of the Congress were very notable. Thus—in connection with wines, it was decided that while pure wine could only be described as the product of the complete, or incomplete, fermentation of the juice of fresh grapes, it would appear that the manipulations are many and various, and that the addition of foreign substances, such as sulphurous acid, and pure alcohol derived from malt, are allowable. In connection with fruits also, sulphurous acid is deemed a necessary addition.

One of the most important discussions took place concerning dairy produce and the use of preservative in butter and other produce. It was decreed that "Boron preservatives" were not only allowable, but were absolutely necessary in the manufacture of butter. It was also held that the addition of such a preservative should not require to be declared in future, any more than the presence of salt would have to be declared, and thus the addition of preservatives would be reduced to the regular operations recognised as being essential to the good conduct of the butter industry. It was also decreed that the standard water contents of butter should be raised from 16 to 18 per cent.

Coffee was clearly defined as being an article of produce without the addition of any foreign matter, from the coffee bean in its entirety, and the addition of chicory in any shape or form, and the extraction of caffeine, were declared to be sophistications, and were prohibited.

Milk, again, was considered to be only worthy of

the name when derived from a healthy cow and could only be regarded as pure when it did not contain any added matter whatever. The subtraction also of any portion of the fat was regarded as being an irregular operation. Pasteurisation, filtration, and refrigeration were regarded as regular operations; but sterilisation, creaming, and homogenisation were declared to be facultative operations, which should be announced at the time of sale.

In connection with drugs, much discussion took place, and a very interesting brochure was presented by the English delegation, which occupied a large part of the discussions. The result may be the appointment of an International Commission to investigate the matter more fully.

Cocoa and chocolate attracted much attention, and there was a long battle between small producers and large capitalists as to what may be tolerated in cocoa. The small producers wanted the use of alkali to be recognised, inasmuch as they contended that, while its use enabled them to produce a cheaper commodity, they also sold the cocoa at a cheaper price than the large manufacturers, and consequently they supplied a great section of the public who could not afford to pay the high prices asked for by the few large manufacturers. Subsequently it was declared that the use of alkali in cocoa manufacture should be tolerated, but that the whole question should also be submitted to an International Commission.

In connection with confectionery it was decided that the use of some 20 aniline colours should be allowed, and ice for alimentary use was defined as being of two kinds—manufactured and artificial. It could be only considered pure when it was manufactured from either sterilised or towns' water, and natural ice should be handled under such conditions as should prevent any exterior contamination, and should be under permanent sanitary control. The use of any other kind of ice for beverages, or in connection with food was prohibited.

These brief references to the decisions arrived at, will serve to indicate the kind of work done, and will also illustrate the fact that the various discussions were taken part in by men who were thoroughly competent to come to a decision on the various matters submitted to them.

One thing was very noticeable, namely, that it became plainer and plainer as the Congress progressed that there was hardly a substance in connection with the food supply, which was not subjected to some kind of sophistication or adulteration, and it became evident also, that if the means could be devised to prevent frauds in foods, it would be an immense gain to every nation, inasmuch as it appeared to be quite common in some industries to employ skilled chemists with a view to reducing the quality of the food, while preserving their external appearance, and that frauds of this kind are daily perpetrated. This more especially affects the poor, who are not in a position to judge of the purity of their food, or to control it in any way.

HOME INDUSTRIES.

The Agricultural Outlook.—With wheat at from 40s. to 43s. a quarter, and probabilities pointing to higher prices, farmers are beginning to ask themselves whether they may not put land now laid down to indifferent grass under the plough again. A few years ago it was assumed that, for many generations at least, the Western States of America would be the chief granary of Great Britain. It was argued that, with at least equal energy and skill, with a climate and soil better adapted to wheat-growing, with an ever increasing supply of labour, and with ever multiplying channels of transport, Western farmers of English race could scarcely fail, ere long, to maintain the same lead in the markets of Europe, as English manufacturers, but for a protective tariff, would be able to maintain in those of America. But sufficient allowance was not made for the rapid growth of population in America. Already the United States have ceased to be the largest exporters of wheat to the United Kingdom; before many years have gone they will cease to be exporters of grain, and before another generation has passed the United States may be buying wheat from Canada to feed their own people. Argentina has now become our chief granary, but there is a tendency in the Argentine to displace wheat with cattle. India sends us large quantities of wheat, but the supply is subject to great variations, and the home consumption grows apace. To make up the deficiency from elsewhere we must look to Canada and Siberia. The potentialities of Canada in this direction are great, but she will hardly do more than repair the decline in the exports from the United States, and cannot do that for many years to come. The wheat production of Siberia is increasing, but the increase is not likely to be very rapid in the immediate future, and meantime the demand is not only increasing in Europe, but in Asia, not only in England and in Germany, but in Japan and in India. It is reasonably safe then to assume that the days of very low prices for wheat have passed, and that farmers may now rely upon the prices of all kinds of grain reaching, and remaining at, a level that will give a fair profit, and a larger one than can now be got from some of the poor grass land. It must not be forgotten in considering possible profits of grain growing in this country that the cost of production is considerably less than it was in what are looked back upon as the halcyon days of agriculture. The self-binder has greatly reduced the cost of harvesting, and in other directions savings have been effected. Wheat with an average crop of four quarters—last year the average was 32·16 bushels—per acre means with the price at 40s. per quarter, £8 per acre, and that of itself leaves a profit. Much too might be done in many directions, and something is already being done, by means of co-operation. In olden times, however low might be the price of wheat, the farmer got the whole, or nearly the whole of it, but now-a-days a large army of middlemen has sprung up, and

a toll is exacted at every stage in the process whereby the national food supplies are brought within the consumer's reach. An extensive application of the co-operative principle to the distribution of farm produce, if not to agriculture itself, may prove to be one solution of the agricultural problem. However that may be, the prospects of agriculture, resting as they necessarily must largely upon prices, are brighter just now than they have been at any time since the middle seventies.

Private Banks—The amalgamation of Stuckey's Banking Company with Parr's Bank deprives the country of one of its few remaining great private bank institutions. Founded at Langport, Somerset, nearly two hundred years ago by Samuel Stuckey, a purely local bank for Gloucester and Somerset, its career has been one of uneventful prosperity. Its head office has remained at Langport, a town of some 2,000 inhabitants, but it holds nearly £7,000,000 of deposits, and it has a larger note circulation than any other bank except the Bank of England. The business of Stuckey's was built up by the gradual and steady opening of branches at places in the west country where banks were wanted, and the number of its branches is now 71. Since 1880 its business has nearly doubled if the amount of deposits may be taken as a guide, and it might have been thought that its controllers would have preferred to continue the separate control of the bank. Parr's was also originally a private bank carried on by Messrs. Parr and Co. of Warrington, but unlike Stuckey's its progress since it took over Messrs. Parr's business in 1865 has been largely due to amalgamations. In its first report it announced that the business of Messrs. Thomas Firth and Son, at Northwich, had been acquired, and since then its amalgamations have been continuous. Among them may be named the Metropolitan and Provincial Bank of Macclesfield; the Wigan Old Bank, Wigan; F. W. Jennings, Leek; Fuller, Banbury Nix and Co., London; Alliance Bank, London; Sir Samuel Scott and Co., London; Shrubsole and Co., Kingston-on-Thames; Croxon, Jones, and Co., Oswestry; Dumbell's Banking Company, Isle of Man; Robin Brothers, Jersey; and many others. At the end of last year its offices amounted to 185, and its amalgamation with Stuckey's leaves it with only six joint-stock banks ahead of it in the amount of its current deposit and other accounts. It is with something more than sentimental regret that many, more especially West country folk, will hear of the absorption of Stuckey's. The rapid disappearance of the private banks is by no means an unmixed gain to the community, but it is inevitable.

Why they are Disappearing.—The disappearance of Stuckey's as an independent organisation recalls Mr. Walter Bagehot and his views upon the future of the private banks. The great uncle of Mr. Bagehot, Samuel Stuckey, founded this bank of which his father, Thomas Bagehot, was for thirty years the controller. For several years Mr. Bagehot himself was manager of local branches of Stuckey's Bank, and on leaving the West of England he supervised the bank's London business. Naturally Mr. Bagehot looked favourably upon the private bank, but five and forty years ago he predicted that the days of small banks would before many years come to an end, and that the difficulties of large private banks are very important. In 1810 there were 40 private banks in Lombard-street admitted to the clearing house—there now is only one, nor is the race renewed. Everybody admits that you cannot found a new private bank. The old ones merge or die, and so the number is lessened, but no new ones begin to increase the number again. No new private bank is founded in England because men of first-rate wealth will not found one, and men not of absolutely first-rate wealth cannot. As Mr. Bagehot points out, in "Lombard-street," in old times the private banks were without rivals. The Bank of England had a monopoly in banking of the principle of association. But now large joint stock banks of deposit appeal to the public. They have a large paid-up capital and intelligible published accounts, and they use them as an incessant advertisement, in a manner in which no individual can use his own wealth. In the business of banking there is an enormous growth of detail. Now-a-days bankers not only keep people's money, but also collect their incomes for them, and the private banker has not the organisation that enables him effectively to carry on this new, ever-expanding, and exacting business.

The Whisky Industry.—In the last ten years, the Scotch whisky trade has been struggling with the consequences of reckless production. Stocks were piled up, so that in the financial years, 1897-8 and 1898-9, no less than 26,000,000 gallons were added to the stocks, and in 1904-5 the total stocks in Scottish bonded warehouses aggregated 121,778,000 gallons. During the past financial year, while the production of home-made spirits in Scotland was increased by 1,611,172 proof gallons, the stocks in bond showed a further decline of 1,460,713 proof gallons, but at the latest date for which the official figures are available, the stock remaining in bonded warehouses amounted to 114,188,000 gallons. The falling-off during the last four years, although varying from 1,264000 gallons to 3,328,000 gallons has been very slight when the immense volume of the stocks is considered, and even without the extra duty imposed by the Budget it must have been a long time before the position could be described as a healthy one. As it is, the imposition of the additional duty of 3s. 9d. per gallon on home-made spirits has been very prejudicial to the trade. The Chancellor of the Exhequer admits that he greatly under-rated the effect of the additional duty upon consumption. The imposition of large additional burdens on a falling industry make it probable that less rather than more will be got out of the tax,

and this has happened with the whisky duty. Consolation may be found in the decrease of crime consequent upon the great fall in the consumption of spirits, but from the point of view of the trade the additional duty has greatly worsened the position.

The Change in the Excise Duties.—Many exaggerated statements have been made with regard to the changes in the license duties that will be effected by the present Budget if it becomes law, but it is apparent that the new scale of duties if finally adopted will greatly lessen inequalities in taxation which are indefensible in themselves and unjust to the small public houses. Under the existing system, while the duties levied on houses of less than £100 annual value represent a ratio of from 53 to 60 per cent. of the mean rateable value, the ratio rapidly declines until, in the case of houses rated at between £2,000 and £5,000 per annum the duties represent no more than 2·7 to 1·3 per cent. of the mean rateable value. Mr. J. E. Allen has given an admirable illustration of the anomalous results of the present scale by pointing out that 100 houses rated at £16 pay £800; 10 houses rated at £160 pay £300; one house rated at £1,600 pays £60. The present proposals go a long way to equalise duties.

CORRESPONDENCE.

BURIED TOADS.

With reference to your note on toads in the Society's *Journal* of the 8th inst., in the course of which you say, "Put him in a dry place and he shrivels up at once," it may be of interest to relate what came under my personal observation a few years ago.

When on duty in the lines one day at Aldershot, I was called over to see a toad which had been cut out of a lump of moss litter. He was in a large, nuggety lump, which had separated out from the bale on breaking it up. This toad was, I think, "made in Germany," and must have been subjected to very great pressure in the wire-bound bale of dry moss litter. He was quite healthy apparently, and I carried him to the canal bank, where I released him.

H. COTTINGHAM.

Halifax, N.S.,
October 20, 1909.

NOTES ON BOOKS.

CATTLE OF SOUTHERN INDIA. By Lieut.-Colonel Gunn, Superintendent Indian Civil Veterinary Department, Madras, 1909. Price Rs. 3.

The "Report on the Material and Moral Progress of India," written by Sir Clements Markham in "the seventies," still holds its own, for well selected, comprehensive, accurate, and profitable information, and above all, for inspiration, as "a Model Blue-Book," for so it was, on its publication, at once entitled by the *Saturday Review*: and the aptest praise that can be accorded to Lieut.-Colonel Gunn's "Report on the Cattle of Southern India" is to say that it deserves to be placed among one's books of reference, beside Sir Clements Markham's "Blue-Book," and Professor Wallace's "India in 1887," as the "Model Bulletin," No. 60 of its series, issued down to this date by the Department of Agriculture of the Government of Madras. It is worthy indeed of comparison with some of Surgeon Buchanan Hamilton's MS. Reports on the Agriculture of Southern India [Malabar, Kanara, and Mysore].

Colonel Gunn deals exhaustively with the technical side of his subject. Excluding the innumerable "lesser breeds without the law" of unnatural selection, there are six great breeds of artificial, or human production to be clearly recognised among the cattle of Southern India; and of these the two chief are those distinguished all over India by the names of "Mysore," and "Ongole"—from a town of the Nellore District. Of all six breeds, and their varieties, full descriptions are given, so detailed, precise, and graphic, that they are quite independent, for the purpose of identifying the originals, of the excellent photographs, 60 in number, that but serve to emphasise the accuracy and vividness of the written specifications of the several types of bulls, milch-cows, and oxen so illustrated; and this is the proper utility of the photograph in such works; in which it should never usurp the place of the letter press, wherein their quickening spirit should first be found.

But Colonel Gunn does not limit himself to an exclusively technical view of the cattle of the Madras Presidency; he tells us also of their agricultural history, and even of their national and political history; and it is this part of his Report that will interest all its readers. As my space is limited it is impossible to refer here to more than his history of the celebrated "Mysore" cattle. They are not so beautiful of form and feature as the statuesque and docile "Ongoles," that might well have provided the model for Myron's "Heifer," in praise of which the Greek "Anthology" has preserved 36 epigrams [Pliny xxxiv. 19 (8)]. But they are more compactly built, and are very strong, and high-spirited, and sound and hard, and fleet of foot, and are especially adapted to roadwork, either for slight draughts or pack loads; the Ongole cattle being more suitable for heavy, and slow, and steady draught work. The "Mysores" of the very highest lineage are named "Amrat Mahal," literally "the Palace of the Immortal drink (compare nectar) of the gods," but in this connection meaning "pails of milk:" and these "Amrat Mahals" are divided into two classes, the "Dodadhana," literally "Strong-bows," and the "Nadudhana," literally "Dwarfed-bows." The herds, or *serwes*, of Amrat Mahals accumulated in Mysore during centuries of Hindu rule, were all seized by Hyder Ali when he over-

ran the Deccan in 1761, but he allowed them to be scattered, and degenerate. His son, Tippu Sultan, however, again brought the herds under State control; and instituted markets for their sale, attending them himself for the purpose of presenting prizes to the finest beasts of the year. Under his patronage the "Mysores" rapidly regained their pristine prestige, and it was thanks to their strong backs and nimble legs that he was able in 1783 to cross the peninsula of India in one month for the recovery of Bednore. They also enabled the Duke of Wellington to execute his marches of unexampled rapidity in India that are to this day the admiration of military men; and they gained for the Bombay Army the credit it required for its superlative commissariat arrangements under Captain Davidson, in the Afghan war of 1842. In 1860 Sir Charles Trevelyan, the destroyer of the Indian navy, to the destruction of which we owe the decline of our influence in Persia during the past fifty years, ordered the grazing grounds, or *kavals*, of the "Amrat Mahals" to be broken up, and the herds dispersed, with again the most fatal results to the public interests. Fortunately, before it was too late, the Government of India reorganised these establishments, although with some difficulty, as it was found that the bulls and cows of the best blood had been purchased between 1860 and 1866 by the prescient Khedive of Egypt, Ismail Pasha. At the present date the condition and number of the "Mysores" of both pedigrees are far in advance of all previous authentic records, and their names and fames never stood higher in India.

The bull and the cow are intimately associated with the religion of India, as with all the religions of antiquity, of which Hinduism is a still living survival; and also with the folk lore of the Hindus. But space again does not admit of any adequate references to these particulars of Colonel Gunn's report in this place. But it is of moment to note that the presence of so many ill-conditioned bulls and cows in India is not due to any neglect of them, as ignorant Europeans are repeatedly found stating, but simply to the mistaken piety that makes it impossible for a Hindu to kill cattle incapacitated for work, by accident, disease, or old age. They are therefore given a free run of the grazing grounds, and grain dealers' stalls, with the cattle still in "active service." This may tend theoretically, but I think scarcely practically, to the deterioration of high graded breeds, but it is no more cruelty than is providing, as we now do in this country, for the unemployable, as well as unemployed, and giving old-age pensions to poor people on their reaching the age of seventy,—instead of their euthanising us all! The household cow is fed of a morning before her master and his family; and an oath by "the tail of a cow," *gaudivya*, is as appealingly, and appallingly binding on a Hindu, as the oath "by the head of a son" was on the ancient Romans [Pliny the Younger II, 20, and Martial XI, 94], and is still on the modern Persians—the Parsis—of Bombay. Speech is personified by the Hindus in the name of the goddess Vach, the Latin "vacca," and "vox," &c., and the English vowel, advowson, &c., and the Hindustani *bhasha* is but a variant of the word. The Sanskrit appears in the Greek γαῖα, "earth," and the goddess "Earth," and βοῦς, "cow," "bull," and "ox," *gau*, "cow," "bull" [or ox], and in composition "Earth," as in *gauchana*, "a wheat field," re- and in the English "cow," Scotice *coo* [the English word, ox, has been identified with the Sanskrit *akshan*]. Finally, the Indian land measure *gauvada*, or *gaukos*, means literally the distance the lowing of "a cow reaches," and *gaucharma*, as much land as can be included within a cow-hide cut into strips [compare our words "hide," and "plow" in their similar significances]: and the linear measure, *gaukarna*, used by Hindu handicraftsmen, literally means the length of "a cow's ear." All this indicates the immeasurable, the abysmal antiquity of the knowledge, the use, and the worship of the cow and the bull among the Indo-Aryan races from long before they divided into Persians, Hindus, Celts, Germans, and Slaves; a process Sir Henry Rawlinson calculated to have extended over at least 50,000 years. To the artistic eye, one of the most beautiful sights—visions—in India, is that of some huge, milk-white "Ongole" lounging about the bazaars with a long chain of huge turquoise blue enamelled beads hanging about its neck. Their colour symbolises the purity. and holiness of the beautiful creature; and thus connects these necklaces with the Forget-me-not, and the blue Iris, and the blue Lotus of Egypt, and the sapphire, called by the Greeks "Truth," and with the "Blue Ribbon of the Garter,"—the garter of Joan Countess of Salisbury; and again with the "blue ribbon" of our modern "total abstainers."

GEORGE BIRDWOOD.

THE OLD AND THE NEW PERU. By Marie Robinson Wright. Philadelphia: George Barrie and Sons; London: C. D. Cazenove and Son. £2 2s.

After many years of travel and residence in this land of romance, Mrs. Wright has set herself to describe "the most interesting of all the South American countries." Let it be said at once that she has succeeded in writing a most fascinating and popular account, which, if it does not, perhaps, contain much material that is new, certainly sets forth in an exceedingly readable and attractive style most of the information about Peru that will prove of service to the general reader. To begin with, she gives what she calls "a passing glimpse of the old Peru;" and if, as she adds, the whole story can only be told in many volumes, she certainly contrives with the aid of some excellent illustrations to give a very suggestive idea of the wonderful ruins of Pachacámac, of the palace of Chan-Chan, with its elaborately carved walls and terraces, and of the buildings

of Cuzco, whose great stones are so cunningly cut and laid that they are still the wonder of the architect. Proceeding, she gives in brief the history of the country, from the Spanish conquest of Pizarro, whose daring was only equalled by his perfidy; of the fate of the unhappy Atahuallpa and the overthrow of the Inca dynasty, and the dark centuries of Spanish misrule. After this short but adequate historical *résumé* she goes on to describe "the progress and development that are evident in every feature of the national life as reflected in the social, political, industrial and commercial institutions of the New Peru." It is impossible to note more than a few of the points on which she touches. Her descriptions of the scenery, scattered at random throughout the volume, are excellent. "Tradition says, that when Maita-Ccapac first led his army across the Apurimac river, some of the soldiers were so enchanted with the attractions of the country, especially the picturesque valley above which the snowy summit of the Misti glistens among the clouds, that they asked the Inca's permission to remain. 'Ari, Quepay!' responded their lord, 'Very well,—Remain here!' and from this exclamation is derived the name of the beautiful city that now brightens the valley at the foot of the Misti—Arequipa."

The natural resources of the country would seem to be boundless. Apart from the immense mineral wealth which still lies buried in the Andes, Peru contains vast tracts eminently suitable for agricultural and pastoral development, while the value of the forests can scarcely be guessed at. Guano—which one might almost call a by-product of the country—between the years 1840 and 1867 brought to the Peruvian treasury the enormous sum of two hundred and twenty million dollars. "Every financial difficulty that arose at that time was met by mortgaging the future returns from the sale of guano; and Peru, counting on the extraordinary and abundant return from this source, met all the demands of the Government without recourse to taxation—a condition unheard of elsewhere in the financial history of the world."

How is it, then, that with all these natural advantages Peru has not made greater strides in wealth and progress? The answer is the Andes, which, while they are indirectly the cause of most of Peru's wealth, at the same time render it almost inaccessible. Some idea of the difficulties of transport may be gathered from Mrs. Wright's statement that Deputies from Iquitos, on the Amazon, travel to Lima, on the Pacific, by way of Europe and Panama, rather than cross their own country, as the foreign trip takes less time. But this state of things will be soon improved. Already the Oroya Railway, the highest in the world, has been pushed across the Andes; a second ascends 14,660 feet as far as Arequipa and Lake Titicaca, and others are now under construction. "The prosperous future of Peru," says Mrs. Wright, "is assured by the patriotism, energy, and enterprise that are apparent in every feature of the national life, and it is certain that the present century will see the wealth and greatness of the country increased beyond anything dreamed of in the days of the Incas and the viceroys."

FORENSIC CHEMISTRY AND CHEMICAL EVIDENCE. By William Jago. London: Stevens and Haynes. 5s. net.

A short time ago Mr. Jago delivered a course of lectures at University College, London, on "Forensic Chemistry," with special reference to chemical evidence, its preparation and adduction. Mr. Jago is both a chemist and a barrister-at-law, and he is, therefore, exceptionally well qualified to understand the difficulties which beset the members of the two professions when questions relating to chemical evidence come before the Courts. The lectures have been republished in their present amplified form at the request of a number of lawyers and chemists, and the book should certainly prove of great assistance to those who have to deal with chemical evidence. It appears to treat the subject in a very clear and complete manner, discussing such questions as the adulteration of food and drugs, the use of preservatives and colouring matters, and chemical evidence both in civil and criminal cases, and embodying the most important judicial decisions on the various points raised.

THE GROWTH OF THE ENGLISH HOUSE. By J. Alfred Gotch, F.S.A., F.R.I.B.A. London: B. T. Batsford. 7s. 6d. net.

The object of this book is to give a short history of the architectural development of the English house from 1100 to 1800, "from its first appearance in a permanent form down to the time of our grandfathers, when it lost much of its interest." The author has during many years made the subject of domestic architecture the study of his leisure time, and in his previous works, "The Architecture of the Renaissance in England" and "Early Renaissance Architecture in England," he has shown that he not only possesses a great knowledge of his subject, but that he can express himself in a simple yet scholarly style. In the present volume the arrangement is chronological; starting with a description of the Norman Keep, Mr. Gotch proceeds to deal with the fortified manor house of the thirteenth century, in which the chief feature is the dominance of the hall, the later manor house of the Middle Ages, the Italian influence which made itself felt in the early sixteenth century, and so on through the Elizabethan and Jacobean periods to the late seventeenth and early eighteenth centuries. In this way the steps in the gradual evolution of the English house are clearly traced, and a careful study of the book should (as its author hopes it will) enhance the pleasure of cultivated people in visiting the ancient homes of their country by enabling them to differentiate one style from another, and "to connect the various buildings with their appropriate phases of history. The numerous illustrations have been carefully selected, and are admirably reproduced.

GENERAL NOTES.

ROYAL INSTITUTION.—The 84th Christmas Course of Juvenile Lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Mr. William Duddell, F.R.S., his subject being "Modern Electricity." The course, which will be experimentally illustrated, commences on Tuesday, December 28, at three o'clock, and will be continued on December 30, 1909, January 1, 4, 6, and 8, 1910.

THE ILLUMINATING ENGINEERING SOCIETY.—The opening meeting of this Society will take place on Thursday, November 18th, at 8 p.m., at the House of the Royal Society of Arts (18, John-street, Adelphi, London, W.C.), when a brief report of the progress of the Society will be presented by the Hon. Secretary, and the inaugural address will be delivered by Prof. Sylvanus P. Thompson, D.Sc., F.R.S., the first President of the Society.

PUZZLE POSTCARDS.—The latest development of the picture postcard is the puzzle postcard, published by Messrs. Raphael Tuck and Sons. It consists of a stoutish envelope of cardboard which, on being opened, is found to contain a picture postcard and a puzzle picture of the scene displayed on the post-card, dissected into some thirty pieces. Various games may be played with these puzzles, the object generally being to see who can complete the largest number of designs in the least time. They should find a ready sale, among the young people, at Christmas time, when they will help to shorten a long evening.

AFFORESTATION IN ITALY.—A report has just been issued by the Italian Secretary of Agriculture on the work of afforestation which has been carried on in Italy during the last forty years. The Government are keenly aware of the value of forests, and are determined to reafforest, as soon as possible, the lands which were stripped of trees when the forests ceased to be protected. One hundred and twenty-two thousand acres of Government land have been planted, of which 69,000 acres, or approximately 108 square miles, were planted in 1907 alone, involving an outlay of nearly two million dollars, and providing employment for a large number of men. Reafforestation has been carried on with such energy that there now remain only about 36,000 acres of Government land in need of planting. During the period under review, the Italian Government, in addition to conducting planting operations on a large scale, have distributed over 130,000,000 young trees and 237,000 lbs. of seed in order to encourage planting and sowing by private individuals.

SANITATION IN TROPICAL AFRICA.—In accordance with the recommendations of the recent departmental committee on the West African Medical Staff, the Secretary of State for the Colonies has appointed the following gentlemen to be an advisory committee on medical and sanitary questions connected with the British Colonies and Protectorates in Tropical Africa:—Mr. H. J. Read, C.M.G., of the Colonial Office (chairman); Sir Patrick Manson, K.C.M.G., M.D., M.R.C.P., F.R.S., senior lecturer, London School of Tropical Medicine; Sir Rubert Boyce, M.D., F.R.S., dean of the Liverpool School of Tropical Medicine; Mr. C. Strachey, of the Colonial Office; Mr. W. T. Prout, C.M.G., M.B., late Principal Medical Officer, Sierra Leone; Mr. Theodore Thomson, C.M.G., M.D., of the Local Government Board; Mr. W. J. Simpson, C.M.G., M.D., F.R.C.P., Professor of Hygiene, King's College, London; Mr. J. K. Fowler, M.A., M.D., D.Sc., F.R.C.P., late Dean of the Faculty of Medicine, University of London. Mr. A. Fiddian, of the Colonial Office, will act as secretary to the committee.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 8... Surveyors, 12, Great George-street, S.W., 8 p.m. Opening Address by the President, Mr. Alexander Rose Stenning.

Geographical, Burlington-gardens, W., 8½ p.m. Mr. Claude White, "Two Journeys in Bhutan."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. S. L. Hughes, "Candidate, Member, and Ex-Member."

Cold Storage and Ice Association (in the ROOMS OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. Discussion on "A System of Units for the Refrigerating Industry."

TUESDAY, Nov. 9...Asiatic, 22, Albemarle-street, W., 4 p.m. Dr. G. A. Grierson, "The Beloved of the Adorable."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Messrs. J. Dalziel and J. Sayers, "The Single-Phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway." 2. Mr. Joshua Shaw, "The Equipment and Working-Results of the Mersey Railway under Steam and Electric Traction." 3. Dr. Charles Augustus Harrison, "The Effect of Electrical Operation on the Permanent-Way Maintenance of Railways as Illustrated on the Tynemouth Branches of the North-Eastern Railway."

WEDNESDAY, Nov. 10...United Service Institution, S.W., 5 p.m. Mr. Douglas Owen, "Our Food Supplies in Time of War."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 8 p.m., Discussion on "The Quality of Effluents in Relation to Standards."

THURSDAY, Nov. 11...London Institution, Finsbury-circus, E.C., 6 p.m. Mr. C. J. Sharp, "English Folk Singers and their Songs."

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Inaugural Address by the President, Dr. Gisbert Kapp.

FRIDAY, Nov. 12...Physical, Imperial College of Science, South Kensington, S.W., 8 p.m. 1. Mr. P. V. Bevan, "The Absorption Spectrum of Potassium Vapour." 2. J. S. Dow, "Some Further Notes on the Physiological Principles Underlying the Flicker Photometer." 3. Dr. F. W. Edridge-Green, "Exhibition of a Colour Perception Spectrometer." 4. Mr. H. G. Savidge, "Tables of Ber and Bei and Ker and Kei Functions, with Further Formulæ for their Computation."

Journal of the Royal Society of Arts.

No. 2,973. VOL. LVII.

FRIDAY, NOVEMBER 12, 1909.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One-Hundred-and-Fifty-Sixth Session will be held on Wednesday evening, the 17th of November, at 8 p.m., when an address will be delivered by SIR WILLIAM H. WHITE, K.C.B., LL.D., F.R.S., Vice-President, and Chairman of the Council. The subject of the address will be "An Imperial Navy."

The following arrangements have been made for meetings previous to Christmas :—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

NOVEMBER 24.—T. THORNE BAKER, F.R.P.S., "Photo-Telegraphy."

DECEMBER 1.—HON. RICHARD C. PARSONS, M.A., "Resilient Wheels for Vehicles." SIR JOHN WOLFE-BARRY, K.C.B., F.R.S., will preside.

DECEMBER 8.—JAMES BUCKLAND, "The Destruction of Plumage Birds."

DECEMBER 15.—H. PEARSON, "The Diamond Fields of Brazil."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock :—

NOVEMBER 30. — SAMUEL SIMPSON, B.Sc., M.R.A.S.E., "Agricultural Development in Nyasaland." SIR HARRY H. JOHNSTON, G.C.M.G., K.C.B., D.Sc., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

DECEMBER 9.—SIR JAMES WILSON, K.C.S.I., "The Punjab."

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

CHARLES CYRIL TURNER, "Aeronautics." Four Lectures.

LECTURE I.—NOV. 29—Aerostats and aeronefs—Ballooning and its future—Possible lines of development—Kites—Birds—Is flapping wing flight imitable?—Soaring flight—Gliding flight—Action of the air on plane and curved surfaces—The leading or "entering" edge—Aspect ratio—The inclined plane—The curved plane — The concavo-convex plane — The gliding angle—Air resistance—Stream-line form—The atmosphere — Different qualities of air—Air propellers.

LECTURE II.—DEC. 6.—Dirigible balloons—Comparative efficiency of different types—The elevator—The ballonnet—The compartment system—Methods of suspension—Stability—Motors and propellers—The ascent and the landing—Harbours—Capacity and utility of dirigible balloons.

LECTURE III. — DEC. 13. — Aeroplanes, helicopters, and ornithopters — Present failure of the two latter—The simple glider—Principles of stability.—The question of automatic stability—The relation of speed to stability—Various methods of obtaining stability — The compartment system — Adjustable planes—Flexible planes—Some suggestions—Starting and alighting—Position of the pilot.

LECTURE IV.—DEC. 20.—Flying-machine motors and propellers—Specialised flying-machines—Differentiation of type—Limitations—Practical results—Uses of the flying-machine—Navigation of the air—Flying by night—Special maps and landmarks—Possibilities in war.

Papers to be read after Christmas :—

H. S. SMITH, "Oxy-Acetylene Welding."

E. COOKE, "The Teaching of Design."

CHARLES JOHN STEWART (Public Trustee), "The Public Trustee and his Work."

CYRIL DAVENPORT, "Miniatures."

KENNETH GRAY, "Heating and Ventilation."

OMAR RAMSDEN, "Goldsmiths' and Silversmiths' Work."

C. G. ZANDER, "Printing Inks."

SYDNEY PERKS, F.R.I.B.A., F.S.A., "The Guildhall: the recent discoveries and restoration."

E. B. HAVELL, late Superintendent Calcutta School of Art and Art Gallery, "Art Administration in India."

GEORGE OWEN DUNN, M.Inst.C.E., Chairman, Bombay City Improvement Trust, 1904-1909, "The Bombay Housing Question."

SIR RICHARD CARNAC TEMPLE, Bart., C.I.E., "The People of Burma."

DR. JOHN MCCALL, Agent-General for Tasmania, "Fruit Production in the British Empire."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 13, February 17, March 10, April 21 May 26.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

February 1, March 1, May 3.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

ALAN S. COLE, C.B., "Textile Ornamentation." Three Lectures.

January 17, 24, 31.

PROFESSOR W. WATSON, D.Sc., F.R.S., "The Petrol Motor." Four Lectures.

February 7, 14, 21, 28.

LAWRENCE WEAVER, F.S.A., "Lead Work." Two Lectures.

March 7, 14.

ALFRED B. SEARLE, M.S.C.I., "Modern Methods of Brick-making." Four Lectures.

April 11, 18, 25, May 2.

JUVENILE LECTURES.

Wednesday evenings, January 5 and 12, 1910, at 5 o'clock:—

PROFESSOR HAROLD B. DIXON, M.A., F.R.S., "The Chemistry of Flame." Two Lectures.

THE DEPARTMENT OF LEATHER INDUSTRIES, UNIVERSITY OF LEEDS.

The city and district of Leeds have long been one of the chief centres of leather manufacture in the United Kingdom, and this fact naturally suggested the idea that a department for the technical study of the subject should be established to do for the trade what the Yorkshire College had done for the engineering, textile and dyeing industries of the West Riding. Accordingly in 1890, after consultation with the leading tanners, a report was drawn up containing definite proposals for the purpose, which were approved in substance both by the Council of the College and by the Leeds Association of the Leather Trade, and somewhat later by the Court of the Worshipful Company of Skinners, who were approached on the subject as the proposal took definite form. As a beginning, the present Professor, Mr. H. R. Procter, who was at that time chemist to an extensive leather works, and who had previously had many years of practical experience in the trade, and was already favourably known as a writer on its technology, was appointed lecturer. In the spring of 1891, in company with a small deputation representing the Yorkshire College and the Leeds Association of the Leather Trade, he visited the leading Continental tanning schools at Vienna and Freiberg in Saxony, and the Technical High School at Berlin, to study their arrangements and methods of teaching. With the knowledge thus gained, a laboratory was at once fitted up at the college, and a course of lectures arranged for the following session, the expenses being met by contributions from the Skinners' Company and from members of the Leeds Association of the Leather Trade.

The department opened with an attendance of nine day students, and a considerable evening class. From that time to the present advanced instruction has been given to a number of day students, as well as teaching of a less detailed character to evening classes. At present there are 19 day and 9 evening students. Two have been working for the ordinary B.Sc., and two for the honours B.Sc. degree in leather manufacture, and ten in different stages of the diploma course.

Among the past students of the department many are now occupying important positions both as proprietors and managers of leather works and in technical education, and, so far, no difficulty has been experienced by satisfactory students in finding suitable employment. The students have been drawn not only from the West Riding, but from all parts of Great Britain, from many of the British Colonies and India, and from the United States, as well as from France, Germany, Austria, Russia, Italy, Spain, and Belgium.

The building is admirably adapted for its purposes, and is probably second to none in the accommodation which it provides for its students. On the ground floor, in addition to a lecture-room and preparation-room, is a covered limeyard and tanhouse fitted with the necessary vats, drums, and paddles for complete tanning on a small scale. Adjoining this is a dye-house with the requisite appliances for moroccos and coloured leathers, and beyond, a large currying shop with shafting and abundant power, not only for driving the machinery which is provided, but for experimenting with new machines which are lent by machine makers for testing or exhibition. This room communicates, by a lift, with the laboratories of the first floor and the drying-rooms and store-rooms in the roof. While the ground floor is mostly devoted to experimental manufacture, the first floor is fitted for scientific study of the tanning process in all its various details. A large laboratory for students, with accommodation for about 30 pupils, a smaller research laboratory for the Professor and a few advanced students, a microscopic and bacteriological laboratory with provision for photomicrography, and a balance room and library are provided, together with a private room for the Professor. On the upper floor, in addition to drying and storage accommodation, is a well-lighted museum containing a large collection of

tanning materials and manufactured leathers to illustrate processes and defects of manufacture.

The course of study is intended, in the first instance, to familiarise students, both by information in lectures and by practical handling of the materials, with the details of the tanning process and the reasons why particular modes of treatment produce particular effects. This knowledge once gained, the student is in a position to judge of the causes of defects, and the changes which it is necessary to make to prevent or remedy them or to modify the leathers produced in such a way as may meet the requirements of the trade. Methods of chemical and microscopic analysis are also taught and practised for determining the purity and value of the various materials employed, and for checking their use in the different stages of the process. In the latter part of the course, students are encouraged to attempt the practical production of leathers in which they are interested, and to study the smaller details of the processes. Particular attention is paid to leather dyeing and the manufacture of coloured leathers, and small quantities of almost all kinds of leather of commercially saleable quality are produced.

In addition to actual teaching, the department undertakes a large amount of research work in connection with the practical production of leather and the scientific principles on which it is based, and the methods of analysis employed in controlling the purity of materials and the conduct of tanning processes. On these points much useful information has been freely given to the trade.

The scientific publication and research work of the department during last year is considerable and important. Among the papers of most practical interest may be mentioned those on various methods of control of tannery liquors, Mr. Bennett's paper on tannage with mimosa bark, which contains many points applicable to other materials, and a method for the detection of sulphite-cellulose liquors, which have become somewhat frequent constituents of mixed extracts.

HOME INDUSTRIES.

The Cotton Industry.—In March of this year the rate for middling American cotton was 4·93d., last week it had advanced to 7·95d. The upward movement has been influenced by Messrs. Neill Brothers' estimate of 10,600,000 to 11,000,000 bales, which compares with a crop for last season of 13,800,000 bales. The price of Egyptian cotton, too, has risen, until last week it was quoted at 11$\frac{5}{16}$d, it being thought in well-informed quarters that the yield will be less than last year. There seems ground for the fear that there may be a shortage of supplies next year. American producers of cotton are in a strong position to hold for even higher prices, as they have already sold enough cotton to meet their most pressing obligations, and they do not at present attach much importance to the proposed curtailment of production by cotton manufacturers. It is considered certain that the American cotton crop this season will be the smallest in proportion to the demand for many years. The Master Spinners' Federation Committee have recommended American spinners to continue running short time until December 6. They have only been working four days a week since the beginning of July, and owing to the appreciation in cotton values it is possible that the short time policy will be continued throughout the winter. Manufacturers claim that prices for the raw material have advanced to such a level that they are unable to produce finished goods to sell them on a profitable basis. A great meeting of members of the Master Spinners' Association is about to be held to discuss the whole situation and decide upon future policy, and it is suggested in some quarters that strong action should be taken by the Committee of the International Cotton Spinners' Federation with the object of stopping the manipulation of prices by speculators.

Wool.—Spinners who have merely looked on at the wool and top markets during the last month have cause for congratulation. The wool of merino quality bought at the last London auction will not make a super 60's top on the average under 2s. 6d., but tops of that quality can now be bought at Bradford for 2s. 2d., and for future delivery at 2s. 1d. Tops made out of wool recently imported into Bradford can only be sold at heavy loss, and the remark applies to wool at sea. There is no evidence that the downward tendency of prices in Australia has received a check. At the last auctions at Brisbane and Adelaide, when at each centre 33,000 bales were disposed of, prices were again lower. Mr. Bertrand Harmer, of Norwich, has just issued a circular to the clothing manufacturing trade, drawing attention to the decision of the Huddersfield Woollen Manufacturers' Association, not to make any allowance in future for patterns. The Association, which is composed of more than thirty large manufacturers in the Colne Valley district, has decided that all patterns above 9 in. by 27 in. will be charged for in full, and that no further allowance will be made for patterns in any form. Mr. Harmer suggests joint action, but this must be difficult to bring about. There is no representative body to defend the interests of the wholesale clothing industry.

The Outlook for Wheat.—The estimate of Russian grain crops recently issued by the Russian Ministry of Agriculture has naturally weakened wheat prices. Early in September the preliminary estimate of the Central Statistical Bureau at St. Petersburg placed the probable wheat crop at 73,250,000 quarters. The Ministry of Agriculture now puts it at 70,125,000 quarters for European Russia, and 11,300,000 quarters for the North Caucasian provinces. Adding the probable crop of Siberia, the total wheat production

for all Russia should be between 85,000,000 and 90,000,000 quarters. Taking the last five years, the Russian crop has averaged 75,000,000 quarters, and the exports 14,500,000 quarters. That gives something over 60,000,000 quarters as the home consumption, so that if the latest official estimate of this year's crop may be taken as accurate, there will be at least 25,000,000 quarters of wheat available for export, which would be a record export, that of 1904, which is so far the largest, being only 22,500,000 quarters. Nor is it only that the Russian wheat crop is far above the average. All the grain crops, with the exception of millet and buckwheat, promise to be larger this year than last, and than the average for the five years 1903-7. The unexpected size of the Russian wheat crop, and the ample present supplies of wheat, may be expected to keep prices easy, but a good deal will depend upon the extent of the Argentine crop. Reports speak well of the weather in that country, but it is feared that serious damage has been done to the wheat crop by locusts. The Australasian crop is expected to be a very large one.

The Australian Preference for British Goods.— At the time when under the Lyne tariff British exports to Australia were given a 5 per cent. preference, it was contended in this country, as, indeed, in Australia, that the preference was too small to have much effect in arresting the decrease in imports from Great Britain, which had been so noticeable in the trade returns of 1905-7. In order to show that this view has proved erroneous, during the visit of the Congress of Chambers of Commerce to Melbourne, in September, the Minister of Customs, Sir Robert Best, circulated a report intended to show that the decline has been arrested by the preference, but, as shown by the report, the "arrest" has been of the slightest. A series of percentage tables in the report shows 35 lines in which the percentage of British imports in 1908—when the preference was first in force—was less than in 1907, and 34 lines in which the percentage in 1903 exceeded that of 1907. The latter list includes confectionery, matches, apparel and attire, socks and stockings, electrical articles, earthenware, jewellery, and blankets. The list of goods in respect to which the 5 per cent. has proved ineffectual includes pickles, sauces, carpets, gloves, woollen piece goods, watches, mining machinery, silks and velvets, fancy goods, oils, bicycles, pianos, bags, stationery, leather, pipes, china, varnishes, and glass ware. The best that Sir Robert can say about the 5 per cent. as it affects British imports is that "the decrease in British importations in regard to the total of the particular items benefiting by preference has been arrested. Thus, comparing 1906 with 1905, the decrease was 0·3 per cent.; comparing 1907 with 1906, it was 2·46 per cent.; comparing 1908 with 1907 the decrease was 0·23 per cent." The effect of the Canadian preference upon British imports has been very much more marked, but then the preference has been more than six times as much.

Colliery Certificates. — The action brought by Messrs. J. and P. Coats, Ltd., against Mr. David Brown, and tried at the High Court of Justiciary, Edinburgh, will, it may be hoped, end the practice of collieries granting covering certificates for coal other than their own. It seems that in December, 1907, Messrs. Coats asked for tenders for 400 to 500 tons of best Bent splint coal for shipment to Barcelona, and accepted Messrs. Shields, Brown, and Ramsey's tender. In January 479 tons were shipped, and a certificate was sent to Messrs. Coats which stated: "This is to certify that we have shipped on board the s.s. *Diamond* at Grangemouth, to order of Messrs. Shields, Brown, and Ramsey, 479 tons of our best splint coal, all freshly wrought and well screened. The Bent Colliery Company, Limited, William New." It was afterwards discovered that only 30 tons of the coal was Bent splint coal. When Messrs. Coats and Co. discovered how they had been treated they decided to institute criminal proceedings. The manager of the Bent Colliery Company, in giving evidence, said that when Mr. Brown applied to him for a cargo of Bent coal he said that he could not let him have it, and they agreed that the only way out of the difficulty was to get some coal of the same quality, and the manager agreed to give his certificate for the coal. He issued the certificate, he said, in the belief that he was issuing a certificate for coal the same as their own. He admitted that he was not correct in describing the coal as "our best splint coal," but he looked upon the certificate not so much as a certificate of origin as a certificate of quality. It was shown in the evidence that there was no criminal intention in this, and that nobody suffered or profited by the substitution of one coal for another. The coal shipped, though it did not come up the shaft of the Bent Colliery, and was not literally Bent coal, came from the same seam, and was, for all practical purposes the same material. But the certificate was false. Messrs. Coats obtained full value for their money, but they did not obtain what they had ordered and they were told had been supplied to them. Mr. Brown did what is quite customary in the trade, he did it in good faith with no intention to injure anybody, but it often happens that certificates are issued in bad faith. In Mr. Brown's case the jury returned a verdict of guilty, recommending the respondent to the utmost leniency of the Court, and the prosecution did not move for sentence, and the Lord Justice Clerk was content to reprimand Mr. Brown formally and dismiss him from the bar, but anybody else now found guilty of the uttering of false colliery certificates will not be let off with an admonition. There is no harm in collieries making up cargoes with other coal than their own when they are short of material, or in authorising their immediate buyer to do so, but the condition precedent is that they inform the consignee of the fact, and obtain his acquiescence.

CORRESPONDENCE.

"THE COLORIST."

My attention has been called to your mention of "The Colorist" in your issue of September 17th, 1909. I am glad to find a disposition for fair play in your criticism, even though "The Colorist" is somewhat misrepresented therein, which no doubt arose from a too hasty reading of the book. This disposition for fair play on your part encourages me to hope that you will print the following reply to your review.

I do not refer to M. E. Chevreul as the latest authority on the subject of colour, as you have it: I distinctly state that his work of fifty-five years ago, which is erroneous, has permeated all colour literature (of an æsthetic nature), since his time.

I will admit that scientific students who investigate colour at the present time, have a knowledge of the Young-Helmholtz theory of colour. Their knowledge, however, is largely confined to theory and light, and few indeed have a practical knowledge of its application to pigments in painting and printing. On the other hand I venture to say that there is not one artist, art student, or colour printer in fifty in the United States, who has not read "The Colorist," but is imbued with the idea that the Brewster theory is the correct one. I am also quite inclined to believe that this is the case in England as well.

On page 12 of "The Colorist" will be found in paragraph 2:—"It is probable that what we call a primary colour is such only in relation to the organ of sight, the eye, and has no such function with light itself independently." On page 43 of "The Colorist" at the top of the page will be found the following:—"It may be well to state here that the minus colours advocated in this book as the primary colours for the subtractive method are primary in the sense that they cannot be duplicated or mixed subtractively by any other colours." Does not this successfully refute your statement that I "do not seem to appreciate that there can be no possible justification for speaking of any colours as being primary in a scientific sense"? And yet when we mention the exact triad which represent the fundamental or basic colour sensations of the eye, why should we not call them scientific?

You state that red, green, and violet can be made to reproduce all other colours; also that red, yellow, and blue as pigments may be made to do the same thing. You will find if you try the experiment that with pigments it is necessary to use not red, but a red purple; not blue as ordinarily conceived but a cyan blue (a greenish blue).

J. ARTHUR H. HATT.

Brooklyn, New York, October 9th, 1909.

EARLY STEAM NAVIGATION.

Frequent articles have appeared of late, generally in connexion with the Fulton Celebration in this country, like that by H. T. W. on "Early Steam Navigation," in your *Journal* of October 15th, which either do not mention the name of the first steamer to cross the Atlantic Ocean or give the credit to the *Savannah* (which only steamed four days of the entire trip). In the Historical Museum at Chicago is a model of the first steamship like those of the present, not an auxiliary steam and sail boat, that crossed the ocean—the *Royal William*. This steamship was built in the forties at Quebec, Canada, went to London under her own steam, having no other means of propulsion, and afterwards was sold to the Spanish Government.

The designer is unknown to the writer, but James Goudie, an articled shipwright* of Greenock, was sent to Quebec to superintend her construction. Mr. Goudie left the model which he constructed, and the plans and description of her construction, to the Chicago Historical Museum where the data are accessible. So after all England can claim the construction of the first steamship to cross the ocean.

ROBERT CRAIK MCLEAN,
Editor, "Western Architect."

Minneapolis, Oct. 25, 1909.

[The first ship to cross the Atlantic by the aid of steam was the *Savannah* in 1819. She started from the town of that name in Georgia on the 27th of April, and arrived at Liverpool on the 20th of June. Her engines were used on 18 days. In 1838 the *Sirius* and the *Great Western* crossed the Atlantic silmultaneously under steam alone. The former started from Cork on the 4th of April, and the latter from Liverpool on the 8th of that month. They arrived at New York on the 23rd of April.—ED.]

A CORRECTION.

In the notice of Colonel Gunn's "Report" in last Friday's issue of the *Journal*, the dislocation of two lines near the top of the 2nd column of page 1018 so obscures the etymologies there detailed, and the conclusions they seem to suggest, that I venture to reproduce the disordered sentences in their definite form, as follows:—"Speech is personified among the Hindus by the goddess Vach; the Latin "vacca," and "vox," &c.; the French *vache*; and the English vowel, advowson, &c., and the Hindustani *basha*, is but a variant of the word. The Sanskrit *gau*, "cow," "bull," "ox,"—and, in compound words, "Earth," as in *gau-chana* "a wheat (literally gram) field," reappears in the Persian *guftan*, to speak; in the Greek γαῖα, earth, and Gaea or Ge, the name of the personified Earth, and βοῦς, "cow," "ox," "bullock" [μόσχος], and in the plural "cattle," "kine," [the "bull" is ταῦρος]; in the Latin "bos;" and in the English cow, Scotice *coo*, bull, and bawl, &c.; "ox" having its root as some say in the Sanskrit *akshan*. Finally, the Hindu land measure *gau-vada*, or *gau-kos*, literally means the

* Goudie was given the last year of his apprenticeship to go to Quebec.

distance the lowing of "a cow pervades;" and the land meausure *gau-charma*, as much land as can be included within "a cow-hide" cut into strips [compare "hide," "plow," &c.]; and the linear measure *gau-karna*, used by Hindu handicraftsmen, literally means the length of "a cow's ear."

It is needless to correct obvious typographical and clerical errors; but while writing it may be as well to add that on the same page 1018, column 1, line 15 from the top, "required" should be "acquired"; and in line 7 from the bottom, "their euthanising us all," should read "our euthanising them all";—including ourselves, on becoming pensionaries.

GEORGE BIRDWOOD.

Nov. 6, 1909.

GENERAL NOTES.

BRITISH LIVE STOCK AND MACHINERY IN JAPAN.—In a memorandum on the subject of the Island of Hokkaido, Japan, Mr. E. F. Crowe, Commercial Attaché at Tokio, mentions that there are two important stock farms on the island, one belonging to the Prefecture, and one to the Department of Agriculture, in addition to two horse-breeding farms belonging to the Government. There are also some large private stock farms. The farm belonging to the Prefecture possesses 247 cattle, mostly Ayrshire and Shorthorn; the amount of butter produced annually is about 7,000 lbs., and the dairy machinery is of a London make. Most of the other machinery on the farm, however, is American. There are altogether 429 horses, comprising thoroughbreds, trotters, Anglo-Arabs, and Clydesdales, and about 200 Southdown and Cotswold sheep. The Japanese, however, do not care for mutton, and the director of the farm is doubtful whether sheep can be kept successfully for the sake of the wool alone. As regards pigs, the stock consists of 80 Berkshires, and experiments are being made in ham-curing. Poultry are represented by Plymouth Rocks. The farm belonging to the Department of Agriculture possesses 80 Simmenthal cattle, 40 brown Swiss, and 50 Ayrshires, as well as 170 Southdown and Shropshire sheep. Mr. Crowe suggests that there is an opening for British machinery here if it were brought more to the notice of the directors and owners of these and other farms on the island. (Names and addresses can be ascertained, on application at the Office of the Board of Agriculture, 8, Whitehall-place, S.W.).

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 15...British Architects, 9, Conduit-street W., 8 p.m. Mr. H. Inigo Triggs, "The Planning and Laying-out of Public Places."

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. J. Garstang, "The Hittites: Progress and Research."

TUESDAY, Nov. 16...Sociological (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers: 1. Messrs. J. Dalziel and J. Sayers, "The Single-Phase Electrification of the Heysham, Morecambe and Lancaster Branch of the Midland Railway." 2. Mr. Joshua Shaw, "The Equipment and Working-Results of the Mersey Railway under Steam and under Electric Traction." 3, Dr. Charles Augustus Harrison, C.E., "The Effect of Electrical Operation on the Permanent-way Maintenance of Railways, as illustrated on the Tynemouth Branches of the North-Eastern Railway."

Statistical (in the Theatre of the Royal United Service Institution, Whitehall, S.W.), 8 p.m. Address by the President, Sir J. A. Baines.

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. O. G. Pike, "Behind Birdland's Veil."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Hon. J. McCall, "Tasmania."

WEDNESDAY, Nov. 17.. ROYAL SOCIETY OF ARTS John-street, Adelphi, W.C., 8 p.m. Opening Address of the 156th Session by Sir William H. White, on "An Imperial Navy."

Meteorological, 25, Great George-street, S.W., 7½ p.m. 1. Mr. C. J. P. Cave, "Methods Employed for Observing Pilot Balloons." 2. Mr. W. Marriott, "Registering Balloon Ascents at Gloucester, June 24th and 25th, 1909," and other papers.

Microscopical, 20, Hanover-square, W., 8 p.m. Messrs. E. Heron-Allen and Arthur Garland, "The Recent and Fossil Foraminifera of the Shore-Sands of Selsey Bill, Sussex."

United Service Institution, Whitehall, S.W., 3 p.m. Captain Howard V. Knox, "Use of Ski, and Training of British Soldiers for Duties on Snow-clad Frontiers."

Child Study Society, 90, Buckingham Palace-road, S.W. Dr. W. C. Sullivan, "The Child Criminal."

Junior Engineers (at the Royal United Service Institution, Whitehall, S.W.), 8 p.m. Presidential Address by Engineer Vice-Admiral Henry J. Oram, "The Propelling Machinery of War Ships."

THURSDAY, Nov. 18...Illuminating Engineering Society (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m. Inaugural Address by the President, Professor Silvanus P. Thompson.

Royal, Burlington-house, W., 4½ p.m.

Linnean, Burlington-house, W., 8 p.m.

Chemical, Burlington-house, W., 8½ p.m. 1. Messrs. B. D. W. Luff and F. S. Kipping, "The Resolution of Symmetrical Derivatives of Phosphoric Acid." 2. Messrs. M. Barrowcliff and F. Tutin, "The Configuration of Tropeine and γ-Tropeine and the Resolution of Atropine." 3. Miss I. Smedley, "Note on the Stereo-isomeric Modifications of $\alpha\beta$ Dibro-benzyl acetone."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Percy Fitzgerald, "The First Printed Book."

Historical, 7, South-square, Gray's-inn, W.C., 8 p.m. Miss M. Morrison, "The Duc de Choiseul's Projects for the Invasion of England (1768-1770)."

FRIDAY, Nov. 19...Society of Women Journalists (at the HOUSE OF THE ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.), 8 p.m.

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Mr. C. R. Enock, "The Architecture of the Incas of Peru."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Mr. H. A. Humphrey, "An Internal-Combustion Pump."

SATURDAY, Nov. 20...Sanitary Institute, Nottingham. Discussion on "The Improvement of City Slums by Housing Reform."
